WHEREAS, Our professional brother, Dr. John M. Swift, who after a successful career, has been removed by an all-wise Providence, therefore,

Resolved, That as a co worker his death is sincerely felt by this society; and

Resolved, That we extend to his relatives and friends our sympathy and condolence; and

Resolved, That a copy of this memoir be spread upon the minutes of our Society and that the same be transmitted to the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, the medical journals of this State, and the *Northville Record*, with the request that they publish the same, and also that a copy be sent to his widow.

Signed: E. B. Smith, David Inglis, J. H. Sanderson, H. C. Wyman.

WILLIAM BRODIE, M.D., born in Philadelphia forty-two years ago, and a graduate of the University of Pennsylvania, died suddenly at Forest Grove, Pa., from nephritis on September 3.

W. H. CRAYNE, M.D., died at Colfax, Washington, August 6, aged 48 years. He was born in Fountain County, Ind., and at the age of nine years moved to Champaign, Ill. He served for one year during the war in a company of Illinois volunteers. He graduated from the St. Louis College of Medicine and Surgery in 1880, and located in Oregon in 1884. He has resided in Colfax, Wash., since 1889.

JOHN ALLEN, M.D., Saco, Maine, September 1, aged 85 years.——Robert M. Pulliam, Richmond, Va., September 5, aged 66 years.——William H. Palmer, M D., Jackson, Mich., September 6, aged 60 years. During the war he was hospital steward and assistant surgeon of the Ninth Michigan Infantry and was also with the Army of the Cumberland during its operations in Kentucky, Tennessee and Alabama.——Professor Gros of Algiers.——P. v. Stern, physician to Russian Embassy at Berlin.——W. Kremnitz, Bucharest, aged 54 years.——J. Goldenhorn, Odessa, aged 38 years; death from surgical infection.——I. Tschetschichin, known by his works on the heat centers, aged 67 years.

MISCELLANY.

Why Not?—We are gravely informed that Dr. Kitasato of Tokio, Japan, is in charge of laboratories where anti-diphtheria, anti cholera, typhoid and erysipelas serums are made; also that his institute, connected with the sanitary society of Japan, contains at least the essential requisites for a bacteriologic course and for the practice of microphotography.

Actionable Words.—To render words spoken of and concerning a physician actionable, the supreme court of Indiana states, in the case of Divens v. Meredith, they must be spoken of him in his professional character. It is not enough that the language disparages him generally, or that his general reputation is thereby affected, or that the words used tend to injure him in his profession.

Indications from the Curve of the Agglutinating Power in Typhoid Fever.—If the curve rises abruptly and falls again, resembling the shape of a bell in its course, the typhoid is benign. In severe cases the curve rises slowly and irregularly, and the prognosis is unfavorable if the agglutinating power falls with the temperature.—P. Courmont, *Semaine Méd.*, July 28.

Personal.—Recently appointed by Governor Barnes: L. Haynes Buxton, M. D., of Guthrie, Okla., superintendent of public health and secretary of board; Wilber Hamilton, M.D., of Norman, vice-president of board. Wilson Lockhart, M.D., has been appointed superintendent of the Eastern Washington Hospital for the Insane at Medical Lake, vice Dr. John M. Semple resigned.

The Continuity of Living Matter.—Prof. Rudolph Virchow, at the twelfth International Medical Congress, lately held at Moscow, re-iterated with warmth in an opening address, his views of cellular life. "Life," he said, "has no other origin than from life itself. Life is in the cell. He who speaks of serum as a vital force apart from cells is wrong. The grand truth of cellular succession may be assailed in the future as it has been in the past, but it will never be thrown to earth."

The "Medical Record" and the English.—The *Medical Record* since the Montreal meeting has become pro English. It has frequently shown its great knowledge of the English people and their customs. In fact, it seems to know everything about the English except their language.

Medical Moscow.—The medical schools and hospitals of Moscow were mostly erected by the generosity of the enormously wealthy wholesale merchant class in that seat of extreme Russianism and devotion to the Church. This fact determines the character of the medical world there, which does not affiliate with the outside world like St. Petersburg. The stately row of clinics, two story palaces with side corridors, extends for a kilometer, and scarcely a year passes without the endowment and erection of some new clinic or hospital. All are heated with hot water, and have electric lights, etc. The number of large and small hospitals is almost endless, although most of them are built on the old-fashioned hospital plan. As many of the professors are connected with the wealthy merchant class, it is not a rare occurrence for one of them to endow some clinic or hospital, or to erect a sectarian school or even a church in the midst of the college buildings, at his own expense.—From A. Sack's letter in the *Deutsche Med. Woch.*, August 12.

The Bacillus Icteroides.—There is great rejoicing in South America over Sanarelli's announcement of his discovery of Sternberg's specific bacillus of yellow fever. The distinguished Italian bacteriologist presented his report at a special afternoon meeting in the theater of Montevideo, before a brilliant assemblage, including the President of the Republic and delegates from numerous medical and scientific societies all over the country. It was published in full in the daily press, in *O Brazil Médico* and other Spanish and Portuguese as well as Italian journals. The bacillus responds to every bacteriologic test to prove its identity and the experiments in the line of sero-therapy already promise important results.

Discretion with Township Trustee.—The discretion to determine whether or not a sick and indigent person, found within a county in Kansas where such person has no legal settlement, can be safely and properly sent to the county where such settlement exists, the court of appeals of Kansas holds, in Stevens v. Board of Commissioners of Miami County, July 31, 1897, rests with the trustee of the township, as overseer of the poor. Upon this ground, it further holds that the county becomes bound for medical services rendered upon an order of the trustee, or overseer of the poor, in a case in which he has, upon investigation and inquiry,, determined that aid ought to be extended to an indigent person so found within his township.

The Shrinkage of the Birth Rate in France has suggested the *Alliance Nationale*, of which Dr. Jacques Bertillon is president. The society was organized early during the year and has induced thirty-eight departmental assemblies to request the passage of a law reducing taxation pro rata to the number of children in the family, and that the same be applied to all financial questions in which the government is a party. In addition, where the number of servants exceeds the number of children, the taxpayer is to be subjected to an exceptional surtax, and all favors at the disposal of the state are to be reserved for the members of large families. Another proposition which is receiving considerable attention is that the government should educate and care for all children over six in any family.

Specific Agglutination Reaction Produced in Filtered Cholera, Typhus and Plague Bouillon Cultures by the Addition of Homologous Serum.—Further progress in our knowledge of the agglutination reaction is announced from the Vienna Diphtheria Antitoxin Institute under Professor Paltauf, by R. Kraus, assistant, in the *Wien. klin. Woch.* of August 12. He secured filtrates through "pukal" of cholera bouillon cultures, absolutely free from germs. To these he added sterile cholera serum (goat serum), and kept at 37 degrees C. In the course of twenty-four hours a precipitate formed, leaving the fluid above it perfectly clear. Analysis of the precipitate showed that it is formed of two albuminoids, one responding to the alkali albuminate and the other to the peptone test. He considers it therefore more than probable that it consists of direct substances from the bodies of the vibrios. Exactly similar results were obtained from filtrates of typhus and plague cultures with homologous serum. But the reaction is totally absent if any other serum is used, and also in experiments with toxin-producing bacteria (diphtheria, etc.).

Mortality Rate Tables.—From the *New York Times* of August 28, we learn that "the table of rates of mortality in the various States of the Union issued by the Hospital Marine Service is practically of little value. Really to learn what is the ratio of *deaths to population* we must know accurately both elements of the calculation. It is only in the larger cities, and not in all of these, that either of the elements is known with anything like accuracy. When we read of an average mortality per 1,000 of 4 in Arizona and 20.96 in the District of Columbia, we feel that the latter may be approximately correct, but that the former leaves us as ignorant as we were before. The general fact of a lower death rate may be accepted, but the ratio of its decrease can not be reached with any certainty from this table."

Intoxication from Medicines.—The *Therapeutische Woch.* began to publish in July a comprehensive alphabetic study of the various cases of intoxication from therapeutic measures reported in literature. We note six cases of intoxication from the use of bismuth and several from boric acid, used internally or externally, one from 0.25 gram chloralose administered as a narcotic, one case of extreme amblyopia caused by antifebrin (3 grams taken in half an hour), many cases of argyria after using argentum nitricum extensively, in which the pigmentation was permanent. The similar pigmentation that has been rarely observed after long use of arsenic disappears with the cessation of the medication. An enormous dose of atropin taken by a morphin eater by mistake and followed by a large injection of morphin, ended in recovery. One case of intoxication from the external use of belladonna is reported, already mentioned in the JOURNAL. The favorable effect of atropin in curing intoxication from over-doses of quinin is noticed. Where there is intolerance Aubert follows 0.5 gram quin. sulph. with 0.0005 gram atropin sulph. The article contains careful studies of the various symptoms of the intoxications, including the effects of drugs taken by mistake and for suicidal purposes.

Board of Health an Educational Institution.—The Board of United States General Appraisers at New York decided, June 1, 1897, in the matter of certain protests of Noyes Bros. & Cutler, against the decision of the collector of customs at St. Paul, Minn., as to the rate and amount of duties chargeable on certain imported philosophical apparatus, that the Minnesota State Board of Health, a body created by the legislature and having for one of its chief purposes the collection of valuable scientific information on sanitary matters for diffusion among the people of the State and for the information of the legislature itself, is an educational or scientific institution entitled to the free entry of scientific apparatus under paragraph 585, act of Aug. 28, 1894. The St. Paul City and County Hospital, which it was shown maintains clinics three times a week, which are attended by students of the Minnesota University free of charge, and which has a laboratory for pathologic, bacteriologic, and chemical work, the board of general appraisers holds is also an educational or scientific institution, entitled to free entry under the statute.

Forcible Reduction of Curvature of the Spine.—Calot's method of forcibly pressing the spine into place under anesthesia, with assistants stretching the body by the head and limbs, has proved wonderfully successful in certain cases, but Monod warns that it is strictly contra-indicated in long-standing humps, as consolidation is then impossible, and there is danger of rupturing the meninges and of general infection from mobilizing an isolated and encapsulated focus of tuberculosis or other infection. But in the first months, or even in older humps, when the number of vertebræ involved is not large, reduction is possible and effective and no trace of the deformity remains if a proper spinal corset is worn for a while. Péan has even secured the complete cure of an enormous hump on a girl of 16 who had been confined to her bed for a year or so with paraplegia and suffered intense pain. The *Bulletin de l'Acadèm. de Méd.* of June 8 contains a cut of the corset recommended by Calot. It is even asserted that by prompt treatment with this method there will be "no more hunchbacks."

The Cream of Tartar Tree.—At a recent meeting of the Leeds Medico Chirurgical Society, Dr. Sharp showed a specimen of the fruit of the cream of tartar tree from [illegible]al.

said it was stated in text-books that the cream of tartar tree was *Adansonia gregorii*, a native of Northern Australia, but it was not possible to say, in the absence of leaves, etc., whether his specimen belonged to this species or to Adansonia digitata, which is a native of Africa, and is called the baobab, monkey bread, or Ethiopian sour gourd. The fruits of both adansonia digitata and adansonia gregorii have a very similar composition. The extract of the leaves of the former evidently contains an agent which checks excessive perspiration; the pulp of both species is employed as a remedy in dysentery, and the juice expressed from the pulp is used as a drink in the fevers which prevail in the districts. Two German observers found tartaric acid and cream of tartar in the pulp, but there seems some doubt as to the species, while an English observer, whose specimen was also doubtful as to species, found chiefly acid malate of potassium.—London *Lancet.*

Proof of Period of Gestation not Necessary.—In the bastardy case of State v. Sexton, the supreme court of South Dakota holds, July 14, 1897, that, as the subject of inquiry is a matter of common knowledge, pertaining to the course of nature, of which courts will take judicial notice, no proof as to the ordinary period of gestation is necessary. The admission in evidence, in this case, of a table contained in a standard medical work giving information as to the average time from the day of conception to the day of the birth of a mature child, leads the court to remark that, when properly objected to, the hearsay character and uncertainty of a medical work, the author of which being neither sworn nor cross examined, is sufficient to exclude the book and all detached portions thereof, such as the table in question. But when it is disclosed that an expert has based an opinion, expressed on direct examination, upon the recitals of a particular medical work, the court says reference may in some instances be had thereto on cross-examination, as a means of testing his knowledge, and determining the value of such opinion. At the same time, the weight of current authority is clearly against the admission of scientific books as evidence of an issuable fact which may be established by the testimony of an expert.

Cultures of the Gonococcus.—The fact that gonorrheal lesions continue to develop when no cocci can be discovered is explained by Wassermann's recent experiences with gonococci cultivated on the pig serum with Salkowski's nutrose (sodium phosphate and casein). Fifteen c.c. pig serum; 30 to 35 c.c. water; 2 to 3 c.c. glycerin and 80 centigrams nutrose; sterilized by boiling over an alcohol lamp for twenty or thirty minutes and adding, at the moment of using, equal parts of peptonized gelose at 2 per cent., which supplies fluid enough for six or eight plates. He found that by adding peptone bouillon and leaving the cocci in these cultures three days an active specific toxin was evolved, which produces an inflammation at the injecting point, fever and pain in the muscles and joints. This toxin is in the bodies of the cocci, as the filtered liquid did not contain it. He was not successful in any attempts to secure immunization with this toxin. Werthheim and Bröse report a few cases of undoubted gonorrheic peritonitis; the former observing the circumscribed form alone, the latter the generalized. Welander has recently discovered the gonococcus in the blood and injections of a culture at the fifth generation produced acute gonorrhea in an individual who had never previously been affected.—*Meeting of Berlin Medical Association*, July 14.

Address of the General Secretary at the Opening of the Moscow Congress.—The total number of members inscribed to date, August 19, is 7,000. Half of these are our compatriots. In the other half, Austro-Hungary and Germany take the lead with about eight hundred members each. France has sent us more than four hundred members, Italy and Great Britain come next with over three hundred. The United States furnishes one hundred and twenty adherents. All the countries of the world, even the most remote, have furnished a contingent; Mexico, for instance, is represented by more than thirty members. To all we wish to express our unbounded gratitude. We thank especially the ladies, who have not been deterred, by the long and wearisome journey, from visiting our country. We greet in them loyal allies, and we are confident that they will help us to forget the fatigues of our long and assiduous labors. We are unable to offer you many distractions in this dead season, although we know that distractions are absolutely necessary to replace the variety in work to which you are accustomed. Variety to us is synonymous with rest. We bid you welcome to the heart of our country. Endeavor to learn to know us, to the end that, when you leave, you will be our friends, as you are already our allies in the only warfare in which we are interested, the warfare against the ills of humanity.

Botulismus Toxin and Antitoxin; "Sausage Poisoning."—The anaerobic bacillus discovered by van Ermengen in the epidemic of meat poisoning at Ellezelle (*Cbl. f. Bact.*, 1896, No. 19) was not supposed to belong to the ptomain group but to the toxalbumins, which include diphtheria and tetanus. This view is confirmed by the Koch Institute for Infective Diseases, which now announces that antitoxin prepared from this bacillus botulinus is not only effectual in arresting the toxic action of toxin injected nine hours before but is able to save animals twenty-four hours after intoxication, even when the nerve cells are already affected to a considerable extent; also that it gradually brings the cells back to their normal figuration or complete regeneration. The symptoms of botulismus intoxication are abnormal secretion of saliva and mucus in the mouth and throat, blepharoptosis, mydriasis, diplopia, strabismus, dysphagia to aphagia, aphonia, obstipation, retention of urine and sometimes disturbances of the respiration and circulation leading to a fatal termination with the manifestations of a bulbar paralysis. No fever nor mental disturbances. The alterations in the nerve cells of the anterior cornua studied with the Nissl alcohol-methyl-blue stain are: 1. The Nissl corpuscles seem to swell and the granules lose their characteristic concentric arrangement, the chromatophilous elements rarefy and disappear, principally around the edge and one pole of the cell. 2. The disintegration of the Nissl corpuscles, which crumble into powder. The cell then appears somewhat enlarged, the otherwise colorless intersubstance dull blue, apparently scattered with fine dust, and prominent in the center the bright tint and distinct outlines of the nucleolus. In the final stage the cell appears to be almost completely destroyed, the nucleolus alone is still prominent in the amorphous mass with ragged edges, more or less atrophic. The nerve cells do not show degeneration until twenty hours have elapsed after the intoxication and weeks must pass before complete restitution. The experiments that prove complete restitution after antitoxin treatment, fully confirm the announcements of Goldscheider and Flatau in regard to the anatomic restitution of injured nerve cells (*Fortschritte der Medicin*, 1897, No. 7), whose experiments included intoxication with "malon-nitril," counteracted with sodium hyposulphite. They also reported further experiments in this line with Behring's tetanus toxin and antitoxin at the recent Congress of Internal Medicine.—Kempner, Pollack and Brieger in the *Deutsche Med. Woch.*, August 12.

The Moscow Congress.—The executive committee have acquitted themselves of their arduous and complicated tasks with zeal and devotion, with judgment and unmistakable good luck and administrative ability. All our justifiable demands are fulfilled and our hopes surpassed. Even for the transportation of the vast multitudes trending eastward, the preparations were adequate and well planned, as was also the case with the arrangements for sheltering and taking care of the crowd after it arrived, which numbers 7,300 members, not including the ladies. Trivial complaints are heard on all sides, of course, usually dissatisfaction because the Russians do not speak the language of the speaker, or disgust at the street pavements, which really deserve all the bad that is said about them. The remedy for the wretched pavements is, however, the innumerable little one horse *Iswostschiks*, rapid and cheap, with their blue-bloused, red-belted, good-natured drivers, which enable one to see at his ease this incomparable, indescribable wonder city. . . . As the theater in which the opening session was held only seats 2,500, not all the members were able to gain admittance, but I was awarded a seat on the platform, where I could watch the long spectacle of the opening session *en amateur*. I saw in the side box the high and mighty protector of the Congress, the Grand Prince Sergei Alexandrowitsch, who disappeared after the preliminary address, by the way. I saw the Minister of Public Instruction, Deljanow, pronounce a Latin greeting, but could not hear him. I heard the president of the executive committee, Professor Sklifossowsky of Petersburg, General Secretary Roth and Prince Galizyn on the part of the city, read addresses of welcome in French. I listened then to the volubility of the various national delegates in turn, and the honorary presidents, followed by Virchow's address on "The Necessity of Accepting the Continuity of Life as the Base of all Biologic Conceptions," and Lannelongue's comprehensive study of "Surgical Tuberculosis." It was all good; rather too much of a good thing, and we all drew a breath of relief when we emerged from the heat of the crowded assembly upon the broad square in front of the theater, with the entrancing view before us of the walls, gates and clustering houses of the "inner city," above which tower the domes and steeples of the Kremlin, the entrance flanked by the imposing palace of the Duma and the historic museum, while the eye was attracted again and again to the golden cupolas of the great church to the right, glittering in the sunshine. The overpowering grandeur of the scene and the attendant circumstances brought a fresh enjoyment of life and a wonderful, and to us Germans rather a disconcerting, realization of the elementary vital strength and energies pulsating in this great, mighty, unique Moscow and the nation it represents. —Editorial chat in the *Deutsche Med. Woch.* of August 26.

The Absorption of Iron from the Intestine.—In the *Presse Médicale*, Chessevant states that Cloetta has made some experiments in regard to the elimination of iron in the economy. For this purpose he used ferratin, which exercises no caustic action on the tissues. His experiments demonstrated that in dogs which were subjected to a milk diet, the iron injected into the veins in the form of ferratin was eliminated by the large intestine. Quincke had also ascertained this by microchemic examination. The author also investigated the means of assimilation of this element when administered by the digestive tract, and he found that 20 per cent. of a dose of ferratin introduced into the stomach of a dog subjected to a milk diet, was absorbed. The organic combination of iron with albuminoid matter is necessary in order to insure its absorption. Two dogs were experimented upon as follows: Their food consisted of a soup made of starch, sugar, glucose and distilled water. To the nourishment of the first dog a solution of iron chlorid representing sixty milligrams of iron was added; to that of the second dog a solution of ferratin representing forty milligrams of iron. The villosities of the dog to which ferratin had been given presented the characteristic action of the iron absorbed. The iron contained in the intestine of the other dog was not absorbed and formed masses at the base of the villosities. The organic iron combined with albuminoids is evidently absorbed in the intestine, penetrates the chyle and enters the circulation by the mesenteric veins.—*New York Medical Journal.*

Prostatic Surgery.—The *Centralblatt f. Chir.*, of June 5, contains a detailed study of nineteen operations to relieve hypertrophied prostate by K. G. Lennander, with complete details of symptoms and results. He expresses his conviction that double vasectomy is destined to become very important in cases of dilatation of the bladder without infection, and with only partial retention of urine, but the rule is imperative that a catheter must never be introduced in these cases except under the most pressing circumstances. He states that this operation should be proposed in all cases in which the catheter treatment does not lead rapidly to comparative relief from the symptoms. If cystitis persists in spite of regular catherization epicystotomy should not be postponed. With this vasectomy can be combined, as recovery is apt to be prompter. He also questions whether it is not the best treatment in chronic urinary troubles, with complete retention but no cystitis, to relieve the bladder with punctures and aspiration and supplement this by vasectomy. It may be possible in this way to avoid catheterization and also cystitis. It is Lennander's practice to remove as much as possible of the connective tissue surrounding the vas. One case, a man of 57, still has natural painless erections at night. The testes remain normal to palpation for a long while. Kohler reports seventy vasectomies in the same number, of which three-fifths were cured, one-fifth improved and one-fifth unaffected by the operation.

Reading Medical Books to Jury.—The authorities, both English and American, are practically unanimous in holding that medical books, even if they are regarded as authoritative, can not be read to the jury as independent evidence of the opinions and theories therein expressed or advocated. One objection to such testimony is that it is not delivered under oath. A second objection is that the opposite party is thereby deprived of the benefit of a cross-examination. A third, and the United States court of appeals suggests (Union Pacific Railway Company v. Yates, March 22, 1897), perhaps a more important reason for rejecting such testimony, is that the science of medicine is not an exact science. It also holds that the Iowa statute which makes "books of science and art" presumptive evidence of facts of general notoriety or interest does not change the rule in that State. In this the court follows the construction placed upon a similar statute in California to the effect that the expression "facts of general notoriety or interest" means "historical facts, facts of the exact sciences and of literature or art," all of which, when relevant to a case in hand, may be proven by the production of books of standard authority, rather than by the mouths of living witnesses. At the same time, the court calls attention to the fact that, while the prevailing rule is as stated, a physician is sometimes allowed, while testifying, to fortify an opinion which he may have expressed, by referring to medical works of standard authority on which his opinion is in part predicated; and, when a medical expert has thus indicated the source of his authority, the books themselves may be offered subsequently for the purpose of showing that they do not support the opinion expressed, or that they contradict it.

Reciprocity of Attack and Defense in the Animal Creation.—M. Albert Gaudry, in a review of the course of development of animate nature through the geologic ages, remarks on a curious analogy between the changes experienced by fishes in the secondary age and those which modern warships are passing through. As soon as the thought of armoring vessels took effect, stronger projectiles were devised in order to penetrate the armor. Then the armor had to be strengthened, and just as rapidly as the plates were made thicker, more enormous projectiles were cast: so that the race has culminated in the construction of vessels so heavy that they are almost unmanageable, and thought is turning again toward light, swift boats. With the secondary fishes, too, offensive arms and defensive armor were developed pace by pace. The teeth were modified till they could crush through the hard cuirasses of the ganoids, and the secondary-age beds are characterized by marine animals thus furnished. Powerful grinding teeth are found in the bony and the cartilaginous fishes, and even in many of the massive reptiles of the trias. The fishes, exposed to enemies whose instruments of offense matched their defensive armor, were obliged to seek safety in flight. Their vertebral column became more solid, so as to furnish a strong support to their spinal muscles, and their tails were shortened and broadened so as to become instruments of energetic locomotion. When this transformation was completed, the carnivorous fishes had no more use for crushing teeth, and they have almost disappeared; no more marine reptiles with teeth like paving stones are found in the tertiary beds or in modern times; and fishes with large teeth working like mill-stones are rare in comparison to those which have thin cutting teeth; and power resides in agility to reach the goal or escape the danger. Existing fishes are marked by an activity that was unknown in the ancient oceans, and justify the observation of Moquen Tandon, that "the agitation and inconstancy of the sea seem to have impressed themselves on the beings which live in its waves, in the suppleness, rapidity and vivacity of their movements."—*Popular Science Monthly.*

Washington.

HEALTH OF THE DISTRICT.—The number of deaths reported to the Health Department the week ending September 11, was 91. Of the decedents 52 were white and 39 were colored. The annual death rate of the total population was 17.1 per thousand inhabitants, being for the whites 14.3 and for the colored 23. There were 4 fatal cases of malarial fever; 6 of typhoid fever; 5 of diphtheria, and 5 of whooping cough, 2 from pneumonia and 7 from consumption.

WASHINGTON ASYLUM HOSPITAL.—Dr. McDonald, resident physician at the Washingron Asylum Hospital, has resigned, and Dr. Stewart Johnson has been appointed by the Commissioners to fill the vacancy.

PHYSICIANS RETURNED TO DUTY.—The following have returned from vacation: Dr. Samuel C. Busey; Dr. Frank Hyett; Dr. James C. McGuire; Dr. S. O. Richey; Dr. Chas. R. Collins; Dr. J. Tabor Johnson; Dr. W. W. Johnston. Dr. Linn E. La Fetra is on a brief visit to the National Capitol, and will shortly return to his post at the N. Y. City Hospital. Dr. James D. Morgan has returned from a brief visit to Montreal, where he attended meeting of the British Medical Association.

COLUMBIA HOSPITAL.—Dr. J. F. McGrath has resigned the office of Resident Physician at the Columbia Hospital and Dr. Wm. E. West of New York, formerly resident physician of the Central Dispensary and Emergency Hospital, has been appointed to fill the vacancy.

Hospitals.

ST. ELIZABETH'S HOSPITAL at Baker City, Ore., has recently been opened for the reception of patients. It is under the control of the Sisters of St. Francis, and will supply a long felt want for hospital facilities in eastern Oregon.

NEW YORK is to have a new home for girl cripples, to be established by the Sisters of the Annunciation, on Washington Heights. The summer home is St. Elizabeth House at Riverbank, seven miles from Stamford, Conn. Here the beneficiaries are taken on the first of May and remain until October. The new house is an old-fashioned residence with large rooms and verandahs on three sides.

THE CHARITY HOSPITAL, New Orleans, is the recipient of $75,000, given by Mrs. Richard Milliken, widow of a wealthy sugar planter, to found a children's building, including a kindergarten.——The Telfair Hospital, Savannah, Ga., reopened September 1, after having been closed two months for improvements.——The Cottage hospital, Des Moines, Iowa, reopened September 1.——The new St. Francis' Hospital, Hartford, Conn., opened August 27.——Conneaut, Ohio, now has a long needed public hospital in the Lyon Hospital just completed.——The Pennsylvania Hospital, Philadelphia, cared for 1,661 emergency cases, treated 1,536 in the out-patient department and 304 in the hospital wards during August, 1897.——The Massachusetts General Hospital is to receive $750,000 from the late Henry Pierce of Boston.——St. Joseph's Hospital was dedicated at St. Joseph, Mo., September 8, an addition having been built at a cost of $4,500.

Societies.

The following recent meetings are noted:

Connecticut—The New Haven Medical Society, ninety-four years old, held its regular session in that city, September 1.

Indiana—The Miami County Medical Association held a meeting at Peru, August 27.

Iowa—The Plymouth County Medical Society was organized at Le Mars, August 24. The Polk Medical Society met at Des Moines, September 7. The Southwestern Iowa Medical Society held a regular session at Osceola, August 19.

Maryland—The Baltimore County Medical Society met at Towson, August 19.

Michigan—The September meeting of the Academy of Medicine of Kalamazoo was held September 7.

New York—The Cortland County Medical Society's quarterly meeting was September 9, at Syracuse. The Medical Society of the County of Queens held its quarterly meeting at Long Beach, Long Island, N. Y., on the afternoon of August 31. "The Diagnosis and Treatment of Fractures" was the chief subject discussed.

Ohio—The Belmont County Medical Society held a meeting at Bellaire, August 31. The Morrow County Medical Society's regular session was held at Gilead, September 6.

Pennsylvania—The twentieth annual reunion of the Pennsylvania and Maryland Union Medical Association was held at York, August 26. The Reading Medical Association's annual meeting was held August 30.

Rhode Island—The Rhode Island Medical Society held its quarterly session at Providence, September 2.

Tennessee—The Sweetwater Medical Association held a regular meeting September 9, at Madisonville.

CHANGE OF ADDRESS.

Bowers, C. E., from Wichita to Anthony, Kan.

Haskin, H. P., from Gaines to Mansfield, Pa.

Martin, Thomas C., from The Lennox to cor. Prospect and Kennard Sts., Cleveland, Ohio.

Porter, G. H., from Benton, Wis., to Steamboat Rock, Wis.

Stewart, F. E., from Detroit, Mich., to care Merck & Co., University Place, New York, N. Y.

Winterbotham, W. H., from Salina, Kan., to 2101 W. Adams St., Chicago.

LETTERS RECEIVED.

Ames, Delano (3), Baltimore, Md.; Anderson, P. L., Chicago; Ayer N. W. & Son, Philadelphia, Pa.

Burrage, W. L., Boston, Mass.; Biedler, H. H., Baltimore, Md.

Caldwell & Co. (Inc'd), New York, N. Y.; Cokenower, J. W., Des Moines, Iowa; Cordell, E. F., Baltimore, Md.; Crafts, Leo M., Minneapolis, Minn.: Collins, A R., Allentown, Tenn.; Colorado Sanitarium, Boulder, Colo.

Dudley, W. H., Easton, Pa.; Drevet Manufacturing Co., New York.

Furay, Chas. E., Chadron, Neb.; Fassett, C. W., St. Louis, Mo.; Fair, H. D., Red Key, Ind.

Griffith, J. P. Crozer, Philadelphia, Pa.; Gardner, Ben. S., Marsden, I. T.: Grube, W. W., Toledo, Ohio.

THE PUBLIC SERVICE.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending September 11, 1897.

Surgeon F. Rogers, detached from the Boston Navy Yard October 4 and ordered to the Norfolk Navy Yard.

Medical Inspector J. L. Neilson, detached from the Norfolk Navy Yard September 30 and ordered to the Boston Navy Yard October 4.

The Journal of the
American Medical Association

Vol. XXIX. CHICAGO, ILL., SEPTEMBER 25, 1897. No. 13.

ADDRESS.

THE WORK OF PASTEUR AND THE MODERN CONCEPTION OF MEDICINE.

Delivered at the Sixty-fifth Annual Meeting of the British Medical Association, Montreal, Aug. 31 to Sept. 4, 1897.

BY PROF. CHARLES RICHET.

DELEGATE OF THE FRENCH GOVERNMENT AND OF THE FACULTY OF MEDICINE OF PARIS.

[From advance sheets of the British Medical Journal.]

It is not without emotion that I rise to address this learned assembly. I know indeed that I am addressing men who are not my fellow citizens, but among them are some, the children of our old French nation, who have the same mother tongue as we; they speak from childhood our beloved French language; they are therefore a little more than my fellow citizens, for they are my compatriots, and I feel myself animated by a truly fraternal affection for them, and as to my English colleagues they have given us evidence of so much good will and of a courtesy so delicate that I need make no great effort to assure them of my gratitude. In one word, although a stranger I seem to be among friends.

I am somewhat troubled also because I am addressing medical men and I am speaking before a medical congress. Now, although I belong in some small degree to the great medical family, since my father has conferred honor upon the profession of medicine by his labors and by his works, and although I have the great honor to be the delegate of the Faculty of Medicine of Paris, yet I am not a medical man, and a physiologist displays some temerity in venturing to speak before you on medical matters.

Still I have an excuse. It is this, that I desire to attempt to bring about a complete reconciliation between medicine and science. It may seem that this is commonplace and that any such attempt would be quite unnecessary. But it is not so, gentlemen. We might find perhaps somewhere, not I am sure, in this assembly, medical men ready to assert unhesitatingly and that there is discord between medicine and science, that all those sciences which are called ancillary, as physics, chemistry, physiology, are impediments with which the clinician has nothing to do. Yes, there are to be found in the world medical men, among them men of even high accomplishment, who are ready still to say: "What have I got to do with your experimental science? Observation of the sick and clinical study are worth more than all your clever experiments, and it is not from laboratories that the means of curing disease can come." Such an opinion appears to me to be erroneous, and I would with all the energy which I possess help to upset it. I hold that it is by experimental science alone that medicine has made and can make progress. It will suffice to describe the work of Pasteur, my illustrious master, in order to give you a convincing demonstration of this.

I shall not be contradicted when I say that the value of this work is greater than all that the history of medicine has given us since the commencement of our era. Through his labors everything has been renewed, regenerated, and, thanks to him, medicine has made more progress in the twenty years than has been made in the twenty centuries.

Louis Pasteur was born at Dôle in the Jura in 1821, and at the beginning of his career consecrated himself to the study of chemistry. He became deeply interested in a difficult and important problem—molecular dissymetery. Here was a question in pure chemistry which would seem to take us very far from medical questions, but it was to lead Pasteur directly to the study of fermentations. If a solution of tartaric acid (in the form of tartrate) be left untouched a change occurs after some time in the chemical constitution of the liquid, which before Pasteur's time had been overlooked. The original solution has no action on polarized light, but after fermentation this same solution has become capable of deflecting polarized light. Pasteur explained this phenomenon by showing that the original tartaric acid is a mixture of an acid deviating light to the right with an acid deviating it to the left, and that a process of partial decomposition takes place; one of the acids is destroyed and the other is not altered, so that the action upon polarized light previously absent by the mixture of the two acids becomes evident. Here we have a fundamental experiment. It is told how, when the young Pasteur desired to show it to Biot, that great physicist who had discovered the phenomena of polarization, the old savant grasped the trembling hand of the young man and before beginning the optical examination of the crystals submitted to him by Pasteur, said to him with tears in his eyes. "*Mon cher enfant*, I have loved science so much that in face of the beautiful experiments which you relate to me I can not prevent myself from being deeply moved."

The explanation given of this phenomenon at that time was that the tartaric acid was decomposed by fermentation. Men were then content to use this magic word, which appeared to explain everything, but which in reality told nothing at all. Neither Lavoisier, nor Liebig nor Frémy had been able to discover its meaning, and were reduced to holding a theory of half organized matter, a childish conception worthy of Paracelsus.

One of Pasteur's experiments, perhaps the most beautiful which he ever made, demonstrated the nature of this mysterious phenomenon. If a sugary solution of carbonate of lime is left to itself, after a certain time it begins to effervesce, carbonic acid is evolved and lactic acid is formed, which decomposes the carbonate of lime to form lactate of lime. This lactic acid is formed at the expense of the sugar, which disappears little by little. But what is the cause of this transformation of sugar into lactic acid? Well, Pasteur showed that the efficient cause of this chemical action was a thin layer of organic matter; that this layer of organic matter consisted of extremely small moving organisms which increased in number as the fermentation went on. Their growth it is, then, which produces the phenomenon of the transformation of sugar of milk into lactic acid. If, for example, we take a sugary solution in which all preexisting germs have been destroyed by heat, no lactic fermentation will take place. But if we introduce into this sterile liquid a small quantity of this layer of organic matter, such as could be obtained from any liquid in which normal lactic fermentation is taking place, we shall see the lactic acid again form rapidly in the new solution.

Let us dwell a little on this admirable experiment. Now-a-days it seems to us so extremely simple that we can scarcely perceive its importance. It seems to us now, in 1897, that from all time we must have known that an organic solution when heated was sterile, and that a germ would suffice to render it capable of fermentation. But this is a mere delusion; no, a thousands times no! This great fact of the generation of germs, was absolutely unknown before Pasteur, and the method of sterilization of liquids and of their inoculation with spores was revealed to us by Pasteur. It is the nature of great discoveries that they become popularized in a short time and thus very soon become elementary. A first year's medical student knows perfectly that which neither Lavoisier nor Liebig, nor Frémy, nor any one before Pasteur, had been able to perceive. One is always tempted to be ungrateful to great discoverers, for their revelations fall rapidly within the domain of common knowledge. They become so simple that they cease to surprise us. We do not think of being grateful, and we forget the efforts which genius has had to make to wrest the truth from jealous Nature. Gentlemen, let us not be ungrateful; let us remember that the recognition of the real cause of all fermentation (the development and germination of organized elements) dates from 1857 and from the celebrated memoir of Pasteur upon lactic fermentation. A new world was then opened to science.

Nevertheless this memoir of Pasteur, containing one of the fundamental discoveries of the century, was not welcomed as it ought to have been. At first its importance was not understood and afterward absurd contradictions were opposed to it. A whole series of beautiful and decisive experiments were necessary to prove that there was no such thing as spontaneous generation, and that sterile liquids remained sterile indefinitely so long as no germs were introduced into them. Pasteur devoted six years (1857-1863) to the proof of the fundamental fact that "organic liquids do not alter until a living germ is introduced into them, and living germs exist everywhere."

A great step yet remained to be taken. This was to determine the evolution of these germs, not merely *in vitro* but in the living organism. We to whom the idea of parasitism and microbic infection is now so familiar can scarcely conceive that it has not always been thus. The microbic theory has become so ordinary, so popular, that we are tempted to believe that the part played by microbes was understood even in the times of Hippocrates, but I assure you that in truth this was not the case, and for long enough after Hippocrates, the power of microbes was not known. Pasteur, to whom, to Sedillot and Littré, we owe the word microbe, was the first also to explain to us in his essay on the silkworm disease, published in 1867, the part they played in the production of disease. He proved that the bright corpuscles found in the bodies of diseased silkworms are living germs, a distinct living species, a parasite which can multiply and reproduce itself and disseminate the contagion.

It was therefore with painful astonishment that I heard Prof. Marshall Hall recently say that the discovery of the part played by micro-organisms in disease was due to Koch and dated from 1876. Now, ten years before this, Pasteur had published his experiments in *pébrine* and *flacherie.*

Davaine had shown the part played by bacteria in anthrax infection, and the idea of infection and of contagion by microbes in the higher animals as well as in the lower had become a common place, not indeed in the medical world, but in all laboratories.

Thus, by successful steps, did the work of Pasteur develop in all its greatness and logic. In the first place, in order to elucidate a chemical problem he studied tartaric fermentation, then he was led to study lactic fermentation, and he showed that they were biologic phenomena. He then pursued the analysis of this phenomena with all its consequences and was led to the conception of disease, due to the development of a parasite.

The normal living being follows out its course of growth without the development of any organic parisite in its tissues or in its humors. But if these humors or tissues happen to be inoculated with an organism capable of developing, then this small living thing multiplies the higher organism infected, and the whole body becomes as it were a culture fluid, in which the pathogenic microbe propagates itself, a center of infection which scatters the disease by sowing the noxious germs wherever it goes. Thus arose the new conception, profoundly new not only for medicine but for hygiene—*Disease is Parasitism.* From thenceforth we understood the meaning of the words "infection" and "contagion," previously mysterious.

It is true that Pasteur did not discover all the microbes of all contagious diseases, but this is of small moment since he was the first to discover that infection was a phenomenon of microbial parasitism. All those who after him have proved points of detail, however important or fundamental they may be, have but followed the path traced by the master. Whether they will or not, they are all the pupils of Pasteur, as those who follow the study of chemistry are pupils of Lavoisier.

The greatest of Pasteur's disciples, Robert Koch, although with some ingratitude he refuses to recognize his master, has only perfected certain points in *technique* and applied his ingenuity and his perspicacity to the solution of questions which in spite of their practical importance are still secondary. He has not, in fact, been able to do anything new except upon points of detail; all that is essential comes from Pasteur himself.

Need I say that this idea of the microbe, of the parasite, has become the basis of medicine. If we take up treatises on pathology written before this prodigious revolution, we shall be astonished by the insignificance and the nothingness of these very ancient books. Yet they are not really very old, they are dated 1875 or 1880, but as one reads them it seems as though several centuries must have intervened between these venerable writings and modern books. I know an excellent article on tuberculosis written in 1878, before the microbe of tuberculosis had been discovered. Well, this article belongs to another age, it belongs no longer to medicine, but to the history of medicine, for it swarms with mistakes and incredible errors with regard to pathologic anatomy, etiology, prophylaxis, treatment; in fact, from every point of view.

In ten years medicine has been entirely overturned and re-made. It is being re-made every day. Every day brings some new discovery in matters of detail, but the great principle is always there and it must always be attributed to the one initiator.

This is not all. Another new and great discovery was to be made by Pasteur himself, and to constitute the supreme development, the culminating point as it were of his life's work. This is the principle of vaccination. By a series of researches, admirable for their precision, Pasteur proved that the pathogenic microbe could be attenuated, that is to say rendered incapable of causing death. But though this microbe does not cause death, yet it can produce the disease; a disease sometimes so attenuated as to be almost imperceptible. Now the living being which has suffered from this attenuated disease is protected against its more serious forms and borrowing the word consecrated by the immortal discovery of Jenner, Pasteur said that we have here *vaccination.*

Fermentation, infection, contagion, vaccination; here in four words we have the work of Pasteur. What more need I say? Do not these four words possess in their simplicity unequaled eloquence?

Can any one longer maintain that the progress of medicine is not due to experimental science? Does not all this knowledge of microbes and of the part which they play in disease imply immediately and necessarily immense progress in therapeutics?

ANTISEPTIC SURGERY.

To take but one example, I will cite the application of microbial theories to surgery.

There was a time when erysipelas, purulent infection and hospital gangrene decimated those upon whom operations had been performed, when puerperal infection claimed a terrible number of victims. It seems to us now-a-days that the medical profession before 1868 were blindfolded and that their blindness was almost criminal. These are now no more than historic memories. A sad history, doubtless, but one which we must look at coolly in order to understand what science can do for medicine. Left to their own resources, practitioners of medicine during long centuries could do nothing against erysipelas, against purulent infection, against puerperal infection, but basing itself upon science surgery has been able to triumph over those odious diseases and to relegate them to the past.

Let me here introduce a reminiscence. When on the occasion of his jubilee, a great celebration was prepared for Pasteur in the Sorbonne, in the presence of the leading men of science of the world, there was a moment when all hearts were softened—the moment when the great surgeon who was the first to perceive how to apply to the practice of his art the theory of pathogenic parasites, when Lord Lister drew near to Pasteur and gave him a fraternal embrace. These two great benefactors of humanity, united in their common work, afforded a spectacle never to be forgotten, a striking reconciliation of medicine with science.

But the apogee of the glory of Pasteur was the discovery of the new treatment of hydrophobia. No one of his scientific conquests was more popular, and from France and from the whole world there arose a long cry of admiration. Perhaps in the eyes of biologists this discovery possesses less importance than his labors with reference to the fermentations and to vaccination, but for the public this was the chief part of Pasteur's work. And men of science also were forced to admire the scientific courage of Pasteur, who putting aside the precise methods which he had bought and discovered knew how to devise new methods to meet the exigencies of the circumstances and how to put them victoriously into practice.

Thus was finished the work of Pasteur. He was spared to take part in the triumph of his ideas and to be a witness of his own glory. If, like so many discoverers, he had sometimes in his earlier days known conflicts and hatreds and petty quarrels and foolish objections, nevertheless he had not to deplore the ingratitude of mankind. He died full of honors, surrounded by admiration, respect and love. For him, renown had already commenced when he died.

And now let us turn back to consider the indisputable union of medicine and of science. This in fact is what ought to strike us in the work of Pasteur. It is not only in general biology and in the progress of our knowledge that his work is great, it is still more in its immediate practical applications. The great biologists of our century, Lavoisier, Claude Bernard, Darwin, have without doubt left behind them work which by reason of its conquests of new births is not inferior to the work of Pasteur, but these new truths do not lead to any such immediate application as antisepsis, the treatment of hydrophobia, anthrax, vaccination, or the prophylaxis of infectious diseases. Pasteur was not only a man of science, he was also a benefactor, and there is scarcely one who can be compared with him as a benefactor of suffering humanity except Jenner, who found out how to preserve thousands and thousands of human beings from the most hideous of all diseases.

Further, Pasteur brought back medicine into the true way of science, even after Magendie, Müller, Schwann and Claude Bernard, it might still have been asked whether all these experiments establishing so many important truths had really been of any advantage for the relief of the sick. To discover, as did Schwann, that living beings are an aggregate of cells; to prove as did Claude Bernard that the liver forms sugar; to establish as did Darwin that living species can be transformed by the influence of long accumulated variations in the environments, these are admirable pieces of work, but work in pure science which had not any immediate therapeutic results. Strictly speaking then it was possible to maintain that clinical medicine did not derive any benefit from such investigations. I do not for a moment believe that this opinion had a shadow of a foundation, but before the time of Pasteur it was not so absurd as it has become since Pasteur. Since Pasteur no man can, without incurring the charge of monstrous inaptitude, refuse the rights of *citizenship in medicine* to experiment and to biology.

And to speak the truth, men of science and biologists, as though their ardor had been redoubled by the renovation of medical ideas, have during these last ten years made discoveries which have introduced into medical science new elements which clinical observation alone had been absolutely incapable of discovering. I will cite a few examples—the action of the thyroid gland, the Roentgen rays, pancreatic diabetes and serum therapeutics.

Physiologists had shown long ago that the ablation of the thyroid gland led to serious results. Schiff had proved this as long ago as 1857, but the explanation of the phenomenon did not become clear until Claude Bernard, but especially Brown-Sequard, had demonstrated the existence of internal secretions of glands which pour into the blood their products that probably neutralize certain toxic substances. This led Vascole and Gley to inject into animals from whom the thyroid gland had been removed, the juice of the thyroid, thus prolonging their existence. The therapeutic conclusion to be drawn was obvious, namely, to treat the unfortunate subjects of cretinism or of diseases of the thyroid gland by the injection of extracts of the thyroid body. You know the result has been most happy.

This new treatment was a true experiment and as is the case with so many experiments the result has been a little different to that which was expected. The ingestion of thyroidin is not only a means of curing goiter and cretinism, but is also a treatment sometimes remarkably efficacious for obesity.

THE ROENTGEN RAYS.

The discovery of the Roentgen rays excited general enthusiasm. The research was made and success obtained, and as a matter of fact it is one of the greatest discoveries in contemporary physics. Now, you are not unaware that this Roentgen ray has been called to play a part, if not in the treatment, at least in the diagnosis of diseases, the importance of which goes on increasing from day to day. Physicists have discovered the principle, it is for medical men to follow up its application.

PANCREATIC DIABETES.

The existence of pancreatic diabetes was suspected vaguely by a clinical physician, Lancereaux, but the means which clinical medicine and pathologic anatomy placed at his disposal did not give him the power to solve the problem. In spite of his perspicacity he could do no more than note a certain correspondence between diabetes and the lesions of the pancreas. How could more have been learnt if we had not the resource of experiment? Two physiologists, Mering and Minkowski, have had the good fortune to show that ablation of the pancreas determines glycosuria, to show that there is a pancreatic diabetes, and they have studied its various conditions with great ability.

SERUM THERAPEUTICS.

I come now to serum therapeutics, a direct consequence of the labors of Pasteur. This is a mode of treatment born of experimental method alone. Here again science has done for the art of medicine that which clinical observation, left to its own resources, could never have accomplished.

Permit me now to show how serum therapeutics is derived directly from physiology and experiment, and pardon me if I am forced to speak of my own work; I shall do so I hope without any vanity. I know very well that we always owe to our predecessors and to our rivals much more than our pride admits, and that the experiments and the ideas which succeed are not always those which have been conceived methodically.

About 1887 M. Chauveau had shown that French sheep could contract anthrax, and that they are very easily infected by the bacillus anthracis, the microbe of anthrax, if small quantities of the bacillus be injected under the skin. But Algerian sheep seem to be safe from the disease. In vain is the bacillus anthracis injected into them; they do not contract anthrax. They are refractory to this disease and possess a remarkable immunity to it. Having reflected on this strange fact I framed the hypothesis that the cause of the immunity of the Algerian sheep, which are absolutely similar from the anatomic and zoologic point of view to French sheep, depended upon chemical substances contained in the blood, and that in consequence we might hope to confer immunity on French sheep by transfusing them with the blood of the Algerian sheep. It is, however, difficult to make experiments on sheep. Therefore, with my friend Hericourt, who has been throughout the researches my tireless fellow-worker, I took animals of two different species, the common victims of physiologists—rabbits and dogs.

Just at that time we had been studying a microbe nearly related to the staphylococcus albus, the staphylococcus pyosepticus, which in rabbits produces enormous subcutaneous swellings when injected under the skin and causes death in 24 or 36 hours. The dog on the other hand seems to be almost refractory to inoculation with this microbe. We therefore attempted to transfuse the blood of the normal dog into rabbits by intravenous injection, but this operation did not succeed, for the transfusion of dog's blood into the veins of the rabbit even in a dose of only ten grams rapidly causes death.

It then occurred to us to resort to peritoneal transfusion in place of intravenous transfusion. In this way we were able to introduce into the organism of the rabbit 50 or 60 grams of dog's blood, and had the good fortune to see the experiment succeed completely. Rabbits transfused with the blood of the normal dog survived the inoculation of the microbe for four or five days, and the rabbits transfused with the blood of a dog vaccinated against the microbe did not die, and were in fact hardly ill at all.

This experiment, which was made on Nov. 5, 1888, is as it seems to me the very basis of serum therapeutics. It in fact proves that the blood of animals refractory to a disease contains chemical bodies which counteract the effects of the specific pathogenic microbe of the disease, and we understood its importance from the first, for having established the general pathologic principle we resolved to apply it to a disease of man.

For several days, then, Hericourt and I debated the question whether we should experiment with one or other of the three diseases—anthrax, diphtheria or tuberculosis. Unfortunately we decided for tuberculosis. Its microbe is easily cultivated and, as you know, it produces greater ravages among men and animals than any other disease. We set to work at once, but, as you will understand, time was required before we could obtain definite results. Still, in a year's time we were able to show that the injection of dog's blood into rabbits retarded enormously the development of tuberculosis. It was, nevertheless, necessary to pass from experimental physiology to human therapeutics. Taking advantage of an observation of Bouchard, to the effect that the serum of refractory animals is as active as the whole blood, we were able to inject the serum in tuberculous diseases. The first sero-therapeutic injection was made by us on December 6, 1889.

At first we had for a time great hope. Yes, in truth, for several weeks we believed that we had discovered the heroic treatment of tuberculosis. For several weeks the various patients that we had under treatment found that their strength was renewed, that their appetite returned, that their weight increased and that cough and expectoration disappeared almost completely. But, alas! it was no more than a transient improvement. A month, or a month and a half, later the pitiless disease resumed its course and the sero-therapeutic treatment turned out to be inefficacious. Happily, while by the most diverse plans we were in vain searching for a method of treating tuberculosis by serum, a German experimenter, Behring, after studying the effects of the serum of refractory animals upon diphtheria showed (in 1892) that this serum is wonderfully efficacious in the treatment of the disease. He applied the serum method of treatment not only to diphtheria, but also to tetanus, and at first in animals and afterward in man he obtained results which were really marvelous. Gentlemen, you know the rest and I need not tell you that this sero-therapeutic method improved and popularized by Roux in 1894 is now a treatment without compare. The statistics on this head are absolutely conclusive. The mortality of diphtheria, which was 45 per cent., has fallen to 15 per cent. That means for the city of Paris alone an annual saving of about one thousand human lives; for the whole of France nearly ten thousand lives. We may take the same proportion for Italy, Germany, England, the United States, Canada and Russia and may estimate the number of infants which serum therapeutics snatch from death at about fifty thousand.

In other diseases the results of serum therapeutics have been much more open to criticism and it would be necessary in order to arrive at a satisfactory conclusion to discuss them in detail. I can not attempt to do this here for it would be an abuse of your patience. I will content myself by venturing the opinion that the last word has not yet been said about serum therapeutics. The organism is endowed with marvelous power of resisting the poisons secreted by microbes. It sets to work in its turn to secrete counter-poisons which neutralize the poisons secreted by the microbe. The antitoxins of the organism combat the toxins of the parasite, and in the future the art of serum therapeutics will be to seek in these resisting organisms the antitoxins fabricated by their cells.

Thus on whatever side we turn we find that medicine has always been guided by experimental science. By experiment and by science it is compelled to march forward. This was true in the time of Harvey, for that immortal physiologist had to meet the opposition of physicians. This was true also in the time of Lavoisier, when by a few decisive experiments he proved the chemical nature of the phenomena of life. But how much more true is it at the present time, since Claude Bernard and above all Pasteur have by experiment laid open a whole world and had warranted us in conceiving the widest hopes for the future of medicine!

The part of the man of science and of the physician are very different. The physician ought to be conservative, applying methodically the teachings and the precepts which he has received. He has no right to experiment upon his patients or to permit human life or human suffering to be risked on fantastic theories. But the man of science ought to be a revolutionist. He ought not to be content with the doctrines which he has been taught. The opinion of the master ought to be but a light weight upon his mind. He ought to seek on every hand for facts which are new and even improbable. Darwin says somewhere that he made the experiments of a fool, and often it is right to attempt that which appears contradictory to all the most received and classic opinions. Without this spirit of adventure, without this scientific daring which opens up new horizons there is no progress.

The task of the explorer or of the pioneer is not that of the physician. He ought to be careful to keep himself abreast of all scientific progress in order that his patients may have the benefit of it, but he can not advance the progress of science, save within restricted limits. Having no right to experiment he is almost powerless to solve the difficult problems which arise.

It is the duty of the chemists, the physicists, and above all the physiologists to grind medicine into the new ways. They have not to take the heavier responsibility of a human life upon their shoulders and nothing ought to check their audacity. You, gentlemen, have not the right thus to be audacious, you need prudence and moderation, and convinced as I am of the power of the experimental science I still think that the applications which the chemists or the physiologists suggest to you should only be accepted with considerable caution. It costs us nothing after a few experiments which have succeeded fairly well to say to the physician, "Try that on your patients." Upon knowing very well that our responsibility is *nil* and that the ancient axiom *primo non nocere*, an axiom which ought to be your strict rule of conduct, does not in any way apply to us. You see, therefore, that it would be unjust to make it a matter of reproach to physicians and surgeons that they have not made great scientific discoveries. This is not their mission. It is theirs to relieve human suffering and to seek among new scientific truths that one which is most proper to relieve or to cure the sick.

Nor can I understand how any one should have wished to create an antagonism between medicine and science. To suppose that they are in contradiction is to show that we understand nothing about either the one or the other. It is not reasonable to assert that the one is superior or inferior to the other; they are different in their means and in their ends. They are mutually complementary and both are equally necessary.

If I were ill, most assuredly I would not seek the assistance of a chemist or a physiologist, and medicine is not to be learned from the books of Claude Bernard or of Pasteur. Clinical instruction is necessary, such as long observation of patients alone can furnish. Prophylaxis, diagnosis, prognosis, therapeutics are not to be learned in scientific books. Something else is necessary—observation, long, patient observation, the old Hippocratic observation, without which there could be no good physician. Young students must be guided in the examination of patients by experienced practitioners and no one I presume would be guilty of the folly of proposing to replace the clinical ward by the laboratory.

But without laboratories the clinical department must remain incapable of scientific advance and this condition of stasis is most assuredly undesirable.

For in spite of all the progress which has been made, much yet remains to be done. Are not tuberculosis and cancer, for example, the opprobrium of medicine? I appeal to all medical men here present. Is there any one of you, gentlemen, who in the presence of such painful modes of death, does not feel himself humiliated to the bottom of his soul by his powerlessness?

Well, this feeling of our present powerlessness against disease ought to stimulate us to work. The work to be done is enormous, and we must none of us grow weary in our work. We physiologists must seek new facts; we must seek and seek again, seek always without being afraid of the boldest hypotheses and without putting any limit to our audacity, without troubling our heads as to the practical consequences which may flow from our discoveries, having only truth, divine truth, for our object. You, gentlemen, it is your duty to follow with the warmest interest both the general effect and the detailed results of biologic discoveries, in order to attempt to find some practical application. From this unceasing collaboration progress will be born. But it is necessary that men of science and physicians should both be animated with these two governing sentiments—faith in science and love of man.

ORIGINAL ARTICLES.

PERSONAL OBSERVATIONS AND EXPERIENCE WITH DIPHTHERIA ANTITOXIC SERUM.

Presented in the Section on Materia Medica, Pharmacy and Therapeutics at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1–4, 1897.

BY I. NEWTON SNIVELY, A.M., M.D.
INSTRUCTOR IN PHYSIOLOGY AND LECTURER ON PHYSICAL DIAGNOSIS IN THE MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA, PA.

In view of the American Pediatric Society's collective investigation on the value of the antitoxin treatment of laryngeal diphtheria, and the favorable comments it is calling forth from the medical press everywhere, the subject seems trite before such a body of representative medical men of our country. The committee of the Pediatric Society spared no pains in making their report, which includes only undoubted cases of laryngeal diphtheria treated with antitoxin, and deserves the highest commendation from the entire profession, as it will undoubtedly be the means of saving many lives by conducing to a more general and better employment of diphtheria antitoxin. The report shows that in operative cases of laryngeal diphtheria before the introduction of antitoxin 27 per cent. recovered, while when antitoxin is used 73 per cent. recover. The committee made the significant statement that even so high a percentage of recoveries is too low, from the fact that many practitioners still lack confidence in the remedy, and either from procrastination on their part or objections on the part of friends use antitoxin too late; others employ the remedy timidly and in too small doses, often one-tenth to one-fourth of the required dose being administered. Dillon Brown in his reply to the report said he fully agreed that the report shows a mortality from laryngeal diphtheria entirely too high, and that in his personal experience from Sept. 1, 1896, to April 1, 1897, the percentage of recoveries in laryngeal diphtheria under antitoxin treatment was 94.7 per cent., only one case out of twenty having died.

Regarding the opposition to the remedy, a report so favorable, resulting from the most crucial of tests made with the greatest care and impartiality, would seem an adequate reply. It is not more than was to be expected, that a remedy promising so much should meet with the keenest opposition. In this, diphtheria antitoxin has simply shared the fate of every distinct advance in medical science. Vaccination, anesthesia, hypodermic medication, antisepsis and the germ cause of disease are only a few notable examples. That antitoxin should still meet considerable opposition is not to be wondered at, considering the short time since its introduction.

The physiologist, the biologist, the bacteriologist and the chemist have all been working hand in hand toward a scientific treatment of diseases based upon the germ theory. The antitoxin treatment of diphtheria is an outgrowth of their researches, is founded on facts which were never universally accepted by the profession, and is employed only by the hypodermic method of medication, which still meets the most vigorous opposition in many communities. "The foundation of the treatment with antitoxin rests on the fact—and it is well to keep in view that it is a fact—that the blood serum of animals immunized against certain diseases contain substances called antitoxin, which when injected into healthy animals will give immunity to the same disease. Further, not only will the serum confer immunity to later infection, but will if not given too late prevent the otherwise fatal outcome of the disease in animals already ill." ("Am. System of Practical Medicine," Loomis and Thompson, vol. 1, p. 692.) "The power of the diphtheria antitoxin to neutralize the poisonous effects of the diphtheria toxin in animals is, as stated before, an absolute fact which has been shown to be uniformly true in thousands of experiments. We have every reason to expect that since the toxin in human diphtheria is, so far as we can determine, exactly the same toxin as that in diphtheria in animals, this power of antitoxin to make the toxin harmless will manifest itself in man under similar conditions." (*Ibid.* p. 693.)

It is evident that the physician who can not accept what he still calls the "germ theory of disease" is not open to conviction even by what Virchow designated the "brute force of figures." It has been well said that there are today probably not over four or five active opponents to the antitoxin treatment of diphtheria, whose names were known to the medical profession before the introduction of antitoxin.

That antitoxin is fully specific in experimental diphtheria is a matter beyond all peradventure. The bacteriologist will today inoculate a number of animals with the same culture of diphtheria bacilli; in half he allows the disease to run its course. The animals go through all the characteristic symptoms of the disease and die. In the other half he stops the process by an antidotal dose of antitoxin and the animals show none of the symptoms of diphtheria and live. If he does this fifty times with the same result, and if fifty bacteriologists all over the world do the same thing with the same results, who will attempt to say that antitoxin is not specific in these instances? If a dose of antitoxin affects inoculated lower animals so favorably is it not reasonable to suppose that it will do the same thing for infected man?

The report comes to us from all parts of the civilized world of hundreds of thousands of cases of diphtheria treated with antitoxin with wonderful success, and these cases represent every phase of the disease, in all seasons of the year, in all possible variations of climate, and under the supervision of thousands of different physicians. Will any one attempt to dispute the honesty, sobriety and judgment of all these medical men? Has there ever been a parallel of antitoxin in all the annals of medicine? Has any drug ever been so uniformly accepted and so unanimously endorsed in so short a time by the profession as diphtheria antitoxin? In spite of all of these facts and the convincing figures of the American Pediatric Society we still see some adverse criticisms in our journals. Usually these critics have not tried the remedy and condemn it only on general principles. If they have tried the remedy and found it wanting in any particular it is because their cases were not a fair test or they used the remedy too late in the disease or in too small doses, or used a poor quality of the serum.

My own experience with antitoxin began Sept. 22, 1894, when I injected a child 8 years of age with 2 c.c. of Aronson's antitoxin on the tenth day of the disease. This was the first case treated with antitoxin in Philadelphia. The antitoxin was supplied by Dr. Lewis Jurist, who had recently received it from New York. It was of the strength of fifty units to each cubic centimeter, or one-tenth that I now use. Dr. Jurist had seen the case with me the day before, confirmed the diagnosis and suggested using the specimen of serum. The test was by no means a fair one. The dose, 100 units, was entirely too small and administered too late in the disease. The child died on September 24, and two days later I myself contracted diphtheria and was disabled for five weeks, but did not have antitoxin used in my own case, as there was none to be had in the city. The first case treated successfully was that of Dr. Muehleck, Oct. 2, 1894, and virtually constitutes the first legitimate trial of the serum treatment in the city.

Since July, 1895, I have used antitoxin in thirty-five consecutive cases of diphtheria freely and persistently. In every case a bacteriologic examination was made by another and disinterested physician and the clinical diagnosis thus confirmed. All of this bacteriologic work was done by the Board of Health physicians, and all the cases showed the Klebs-Loeffler bacilli with the clinical history of true diphtheria. In addition to the thirty-five cases of true diphtheria one dose of antitoxin was administered in eight cases which showed every aspect of true diphtheria, but in which the bacteriologic examination revealed no Klebs-Loeffler bacilli. For this reason these are excluded from this report; but I wish to say that all recovered. The pseudo-membrane in the majority of cases promptly disappeared and the antitoxin seemed to have only good effects. Besides administering antitoxin in five cases for other physicians which are not included in the above thirty-five, I immunized twenty-eight persons, none of whom contracted diphtheria.

It is not my purpose to speak at length of the clinical history of each case, but simply to classify them and report only the special points of interest in a few of the cases.

There were six cases of membraneous croup or laryngeal diphtheria with one death. The fatal case occurred in a child of four and one-half months, who was attended by a homeopathic physician for five days prior to the time when I saw it. It seemed as if the child would live only a few minutes, so severe was the stenosis. I immediately intubated and injected 1,000 units of antitoxin. The patient was much relieved by the tube, rested comfortably and even took some nourishment. In six hours I injected 1,000 units more in the hope that I could counteract the effects of the toxins, but thirteen hours after intubation the child died from broncho-pneumonia and exhaustion.

All my cases except the fatal one were injected on or before the fourth day of the disease. Two were injected on the fourth day, twenty-one during the first twenty-four hours, ten during the first forty-eight hours, one on the third day, two on the fourth day and one on the sixth day. The ages of the patients varied from four and one-half months to twenty-eight years. Two of them were 2 years or under, fifteen were between the ages of 2 and 4 years, twelve between 4 and 10, and six more than 10 years of age.

The amount of antitoxin used at each injection was regulated largely by the conditions. If the case seemed to be a bad one or had continued a length of time, a large initial dose was given. Frequently 2,000 units were given to a child 3 years of age and repeated in twelve hours if the patient had not improved sufficiently. I preferred to give too much rather than too little; that is to err on the side of safety to the patient.

Concerning complications in these cases I have only to say that since employing the serum treatment I see comparatively few complications in diphtheria. One of the above cases which developed a rather serious complication was that of a little boy 3 years old, who was injected on the fourth day of the disease. The child was suffering from laryngeal diphtheria and the parents were told by an experienced physician who, however, had not used antitoxin in the case, that the child could not recover. When seen at midnight the case seemed hopeless. The patient was bringing into play all of the extraordinary muscles of respiration. I intubated at once and then injected 2,000 units of Extra Potent antitoxin. I remained with the child myself for several hours to study the effects of the remedy and if necessary remove or reinsert the tube. It was truly a pleasure to note the change in the child's entire condition. Respirations became easy and regular, his countenance was more natural, and he fell into a restful sleep. When seen the next day he was comparatively comfortable and had taken quite freely of milk and whisky. I, however, injected 2,000 units more ten hours after the first injection and allowed the tube to remain forty-eight hours. I found it necessary to administer a third dose on the fourth day, making in all a total of 5,000 units. This patient developed suppurating cervical glands from streptococcus infection, also paralysis involving the faucial muscles and the muscles of the lower extremities, but is perfectly well today.

In all my cases the urine was examined at the time the antitoxin was injected, and forty-eight hours after if it was possible to secure a specimen. Not a single case examined showed kidney complications after the injection if they were not present prior to the administration of antitoxin. I do not believe the kidneys are ever effected by the treatment, but that when the urine shows the presence of nephritis this is the result of the diphtheria, or that the condition existed prior to the disease.

With the exception already noted, my experience has been with the Philadelphia product (Mulford's) and recently entirely with the concentrated form. I can fully endorse what has been said by the American

Pediatric Society and others regarding the superiority of concentration in antitoxic serum.

In studying the literature of the opponents to the antitoxin treatment of diphtheria the two facts to be noted are, first, that the great mass of it belongs to the first two years of the antitoxin period; and second, that in recent criticisms the tactics are entirely different from those in the earlier charges. I may state here that in taking up this subject I had before me a complete file of all the claims of the opposition, and that no pains have been spared in studying each feature and attaching thereto its full importance. While time does not permit, nor indeed the occasion demand, that every detail be taken up, I purpose to select those claims which, to the physician unfamiliar with the production and value of the remedy, seem to have most weight.

The earliest charge was that antitoxin is only another product of the German laboratory and that it possesses no more value than did "Koch's lymph." As the figures from the hospitals where it was being tried disproved this assertion and the remedy began to be employed in private practice, every conceivable ill effect was ascribed to the remedy. A summary of these so-called ill effects, it is to be noted, contains every effect which classic descriptions of diphtheria ascribe to the disease. Matter of this kind makes up the mass of the early literature and is the great reference library to the physician who can not accept the germ cause of disease, or who is otherwise by principle antagonistic to progression in therapy and who wishes to place himself on record as opposing a "fad."

The occasion of much of the displacement of cause and effect was an early misconception of the non-toxic character of antitoxin. In the process of production it was reasoned, contrary to facts, that the horse was inoculated with the disease (diphtheria), and that the serum employed is consequently not the serum of health. The bacillus diphtheriæ, after developing powerful toxin, is killed by the addition of 1 per cent. trikresol or 2 per cent. carbolic acid, and the dead bodies of the bacilli filtered out of the bouillon containing the toxin, so the pure toxins only are injected; the horses can not, therefore, be given diphtheria any more than a patient taking strychnia could have a tree of nux vomica grow from him.

Since the volume of testimony in favor of antitoxin has become so large, the opposition is narrowed down to one or two of several claims here briefly stated: 1. Antitoxic serum is a foreign body in the system. 2. We do not know the nature or mode of action of the remedy. 3. It is uncertain in action and occasionally disastrous in effects. 4. The virtues of antitoxic serum are due wholly to the preservative contained.

Blood serum is not a foreign product in the animal economy, a fact which can not be stated of quinin, morphin and a thousand other recognized remedial agents.

Antitoxin has been found in small quantities in normal blood and in mother's milk.

It is true that we know little of its nature, except by its effects; yet this is equally true of other remedies, notably electricity. We do not know specifically how it acts, nor do we know how many other remedies act. But we do know that it either acts by neutralizing the toxins secreted by the diphtheria bacilli or by rendering the system tolerant to these toxins.

The claim that antitoxin is uncertain in its action arises from a failure to appreciate the therapeutic application and limitations of the remedy. In point of fact, diphtheria antitoxic serum is one of the most certain remedies in modern therapeutics, and this is the testimony of thousands of physicians who are relying solely upon it. As one of many who could be quoted, I present this by Dr. Wm. H. Park, professor of Bellevue Medical College: "I have seen, in watching more than 1,500 cases, no serious effects upon the heart, kidneys or nervous system which could be attributed to antitoxin, with the possible exception of two cases of scarlatina complicated with diphtheria. In these cases there was complete suppression of urine, which was probably due to the scarlet fever and diphtheria and not to the antitoxin." ("Practice of Medicine," Loomis and Thompson, Vol. I, fol. 701).

The so-called fatal cases, of which there are five or six that can not be satisfactarily explained because the proper data can not be secured, have called forth much of the recent opposition. One writer has seen in the use of antitoxin a possible medico-legal question, in face of the fact that every mortality rate where antitoxin was used shows a great saving of life. Dr. J. J. Kinyoun of the U. S. Marine-Hospital Service has stated that if antitoxin could have been secured and employed in every case of diphtheria in the United States during the past five years, at the lowest estimate 150,000 lives would have been saved. In this he but voices the sentiment of all the advocates of the serum treatment of diphtheria. Dr. Abraham Jacobi has said: "Nor is there a practitioner but has the right, or rather the duty, of giving antitoxin a place among his most reliable remedies. If present experience is confirmed by many more similar facts, it will be entitled to be claimed as a specific, though it have not the power to cure every case of diphtheria any more than quinin cures every case of malaria or mercury of syphilis" (Paper by Louis Fischer, *Medical Record*, Dec. 24, 1896). This statement was made before the supplementary report of the American Pediatric Society of which the *Medical News* says editorially, May 15, 1897: "The final word is spoken—a fact is before us." We have no other remedy that has half the evidence in its favor that diphtheria antitoxin now has, and the time is before us when the physician who ruthlessly permits his patients to die for want of a timely dose of antitoxin will be held chargeable at law.

Regarding these so-called fatal cases, Louis Starr writes: "That the antitoxin in itself is practically harmless may be considered as well established, in view of the countless number of injections that have been made (now numbering over a million, A. Jacobi) with but a few fatalities attributed to its use; and in these cases the evidence is either so complete as to clear the injection of all blame, or so incomplete as to allow of no positive deduction. The unpleasant effects occasionally noted, such as amorphous eruptions, fever and painful joints, are clearly due to the serum and not to the antitoxin; and as more concentrated serums are being put on the market these may be confidently expected to grow less in number, since the quantity of serum to be injected will thus be lessened in amount." ("Gould's Year Book of Medicine and Surgery," fol. 758.)

Various explanations of these cases have been advanced, but since the required data are wanting, none are satisfactory. The claim has been made that by error in the production of the antitoxin a trace of toxin in the serum remained and was the cause of the death. This is impossible for three reasons: 1. The horses are not bled till several days after receiving the last toxin, and then only if the trial bleeding shows the presence of sufficient antitoxin. 2. The presence of toxins could not escape detection in the delicate process by which all antitoxin is standardized before being bottled. Again, diphtheria toxins in their most virulent form do not cause sudden death. In the instances cited untoward symptoms appeared immediately and death followed within five or ten minutes after injecting the antitoxin. To say that the serum was contaminated by pathogenic bacteria will not adequately explain, because no germs found in nature are capable of causing death within a few days, while those produced in the more favorable artificial cultures can not cause death, even in small animals, within several hours. The cases simply remain unexplained, and must be considered incidental to the treatment and not accidental. They have their parallel in the instances of other remedies of which cases are not reported.

It will be recalled by many that fatality was frequently attributed to the hypodermic method of medication when first introduced, and that many physicians even now refrain from employing the hypodermic syringe in patients apparently moribund.

There is no means possible by which we can determine the amount of toxin which has been absorbed or secreted by the diphtheria bacilli in the patient suffering with diphtheria, and therefore the only safe thing to do is to give a quantity of the antitoxin which will be sufficient to neutralize any quantity of toxin that may be secreted. The remedy is a harmless one, and if any mistake is to be made it should be on the safe side of giving too large, rather than too small a dose.

Finally, the charge that the virtues of antitoxic serum are due to the preservative and not to the antitoxin, is one which answers itself. The fact that one brand of antitoxin contains no preservative and that another contains only a pellet of insoluble gum camphor is sufficient. However, serum is too unstable a product to depend on when not well preserved. That carbolic and phenic acid will not, when administered hypodermically, yield all the results claimed for antitoxic serum is sufficiently evidenced by the fact that it is nowhere so employed.

I can not close this paper without again referring to my unbounded confidence in antitoxin, which has been bred by personal experience and the favorable comments from numerous competent observers. I believe it will do more toward prolonging the average human life than any remedial agent discovered during the present century. In my first twenty cases I used other treatment in connection with the serum, but as my experience with antitoxin increased and as I witnessed the results obtained by it, I began to rely entirely on this remedy. I now approach a case of diphtheria with none of my former dread, and feel that if I can see a case reasonably early my results will be uniformly successful.

2501 Oxford Street.

The New York State Commission in Lunacy reports a slight decrease in cases. On August 1 there were 21,730 inmates of public and private asylums, while on September 1 there were 21,699.

STATISTICS OF SIXTY CASES OF TYPHOID FEVER COMPLICATED WITH HEMORRHAGE FROM THE BOWELS.

Presented to the Section on Practice of Medicine at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, June 1-4, 1897.

BY ROLAND G. CURTIN, M.D.

PHILADELPHIA.

During the last twenty years I have kept large card boards on which were the headings of the more important points to be observed in connection with hemorrhage of the bowels in typhoid fever, and whenever a case occurred of which I could secure the data, it was placed under the appropriate headings. In thus tabulating sixty cases we have a chance to observe the relative frequency of symptoms and fatality, as well as the effect of location, season, climate, epidemics, and other conditions which have an influence on the disease.

In giving you a report of the sixty cases that I have collected, the first point to which I will refer will be that of *age*.

Between the	ages of	10 and 15	years	there were	3 cases.
"	"	15 and 20	"	"	9 "
"	"	20 and 25	"	"	15 "
"	"	25 and 30	"	"	15 "
"	"	30 and 35	"	"	9 "
"	"	35 and 40	"	"	3 "
"	"	40 and 45	"	"	4 "
"	"	45 and 50	"	there was	1 case.
"	"	55 and 60	"	"	1 "

You will observe that there are no cases reported under the age of ten years, but this may be accounted for largely by the fact that forty-eight of the sixty were drawn from hospitals where adults are generally treated.

The next point that I will consider is the sex of the patient. I find that the tables indicate that there were twenty-two females and thirty-eight males. In the Philadelphia Hospital, from which a large number of these cases were secured, the average number of male patients greatly exceeds the female, their statistics showing that, in the past ten years, 554 males, with 134 females, were treated. Taking the general statistics of the disease, the proportion of males would not be so great as this report would seem to indicate.

I published a clinical lecture in the Philadelphia Hospital Reports, in 1893, giving statistics of the first seventeen cases that I had gathered up to that time. Of this series five died and twelve recovered. Seven were treated at their homes and ten in the hospital, and of the five deaths but two were private cases.

In the last series of forty-three cases the mortality increased, twenty-three having died while twenty recovered. In five private cases two died, and in the hospital twenty-one died and seventeen recovered, making the mortality over one-half. What is the cause of this increased mortality?

These later cases have been collected since the introduction of the cold water treatment, which is used quite generally in the hospitals from which the cases were taken. In the private cases cold sponging was resorted to in every case reported in the last series.

Upon investigation I found that since the cold water treatment was instituted the number of hemorrhagic cases has considerably increased, according to the hospital records that furnish the data, and in addition the mortality of the hemorrhagic cases largely increased, viz., from five in seventeen, less than one-half, to twenty-five in forty-three cases or over one-half. Another factor that must not be lost sight of is that for the past eight years we have had in our midst the more or less constant influence of the epidemic of influenza, which has caused a catarrhal fever, accompanied in some instances by hemorrhage of the bowels. In two such cases I have had the opportunity of making autopsies, and I have the report of a third where hemorrhage of the bowels occurred quite early in the course of the fever, causing death. In one instance the hemorrhage occurred first on the sixth day and death on the eighth. In these three cases no evidence of any disease of Peyer's patches or solitary glands was discovered.

If this influenza is capable of causing hemorrhage, why could not the influence which it has been exerting on a large percentage of the population for the past eight years, be a factor in producing hemorrhage in typhoid fever with which it is often complicated? It is well for us to study these statistics, which seem to indicate that something is increasing the number of hemorrhagic and fatal cases of typhoid fever.

Let us see what the effect is following the free use of cold to the surface as is so universally done in the hospitals. When you take into consideration that the application of cold drives the blood from the surface of the body, it must necessarily be followed by an increased amount in the interior, causing a congested condition of the internal organs, and if there happens to be a blood vessel weakened or opened by the operative process, it may give way or a clot be dislodged and a hemorrhage follow. The necessary disturbance in giving a cold bath, or the reaction following it, may have a tendency to produce the same result.

On inquiry I find that in two of the tabulated cases the hemorrhage seemingly took place while the patient was in a bath, and in one case immediately after a bath. One hemorrhage occurred while the patient was in a cold pack, and two just after a cold sponge.

These statistics would seem to indicate that it would be well to avoid cold applications to the skin where there is a tendency to hemorrhage, or where it has already occurred. I would also suggest that during the third week, when the sloughing process is most active, the cold bath or pack, if used at all, be used with great care, avoiding sudden and marked impressions on the external circulation. We may in this way avoid making the case a hemorrhagic one.

Temperature and hemorrhage.—A study of the temperature shows that in twenty-six cases it was lowered by the hemorrhage, in nine there was no seeming effect; and in seven there was an elevation immediately after, while seventeen were not noted one way or the other. By these figures we find that the fall in temperature is the best index of the time that blood is being lost, if the amount be large.

The bloody stool usually takes place some time after the hemorrhage has occurred, especially if it has not been severe. We can easily imagine that a patient might have a small hemorrhage today and if he was at all constipated the blood might remain in the bowel for one, two, or three days before being discharged: therefore we must not necessarily think, when we see blood coming from the bowel, that the patient is having a hemorrhage at that moment, for he may then be safely over it.

Color of the blood.—In six cases it was reported bright red; in fifteen it was altered; clotted in one; first bright red and then altered in twelve cases; dark and clotted in eight; venous in one; bright and dark red mixed in three; tarry in seven; not clotted and then bright red in two; not noted in six.

When the blood is quickly expelled it is less apt to be changed than when it is retained for a time in the bowel, as it then becomes altered by the intestinal secretions.

The length of time hemorrhage continued was 2 hours in 1 case; 6 in 2 cases; 12 in 3 cases; 1½ days in 2 cases; 1 day in 15 cases; 2 days in 8 cases; 3 days in 6 cases; 4 days in 2 cases; 5 days in 1 case; 6 days in 4 cases; 7 days in 1 case; 8 days in 1 case; 10 days in 1 case; till death in 1 case, and was not noted in 12 cases.

The number of hours was 1 in 24 cases; 2 in 15; 3 in 4; 4 in 3; 5 in 3; 6 in 4; 7 in 1; 8 or more in 4; and not noted in 1 case. No doubt, in some of the cases, each passage was counted as a separate hemorrhage.

The day of first hemorrhage was 1 on the 6th; 1 the 7th; 1 1 the 9th; 3 the 10th; 1 the 11th; 5 the 12th; 4 the 13th; 2 the 14th; 4 the 15th; 7 the 16th; 2 the 17th; 2 the 18th; 3 the 20th; 2 the 21st; 1 the 22d; 1 the 23d; 4 the 24th; 1 the 26th; 1 the 29th; 2 the 30th; 1 the 33d; 1 the 35th, and 1 on the 10th day of relapse.

The day of second hemorrhage was the 7th in 1 case; 11th in 2; 12th in 1; 13th in 1; 14th in 4; 15th in 2; 16th in 3; 17th in 3; 18th in 2; 20th in 1; 21st in 1; 22d in 2; 24th in 1; 25th in 1; 29th in 2; 31st in 2; 34th in 1; 35th in 1; 38th in 1; not at all in 13; not noted in 9; 11th day of relapse in 2; and after the first 30 days in 1.

The probable total amount of hemorrhage was 2 oz. in 3 cases; 3 in 1; 5 in 1; 8 in 1; 12 in 2: 1 pint in 8; 1¼ pints in 6; 3 pints in 7; 1 quart in 4; 2 quarts in 8; 3 in 4; noted as profuse in 2; very severe in 1; small in 1, and not noted in 9.

Complications as follows occurred: Neuritis in 1 case; uterine hemorrhage in 1; malarial hematozoon found in 1; periostitis and phlebitis in 1; la grippe in 1; phlebitis in 1; furnucles, meningitis in 1; organic heart disease in 5; furuncles in 1; excessive nervousness in 6; purpura hemorrhagica in 1: pneumonia in 2; late epistaxis in 3; nephritis in 1; convulsions in 1; otitis media in 1; cardiac murmur in 4; perforation in 1; pulmonary congestion in 1; none in 14; not noted in 16.

Unusual epistaxis.—Marked in five cases; unusually present in eleven; not present in twenty-four; and not noted in twenty.

Hemorrhagic diathesis.—Marked in one case; suspected in 5; not noted in 16; and no suspicion in 38.

Sequelæ.—Acute phthisis in two cases; anemia and periostitis in one; prolonged convalescence in two; prolonged convalescence and anemia in one; furuncles in one; phlegmasia in one; periostitis in one; not noted in seventeen; and no sequelæ in seventeen.

The conditions that seem to indicate a fatal termination in hemorrhagic typhoid fever cases are:

1. A tympanitic condition of the abdomen with a continual discharge of black clotted blood. The blood vessels may sometimes be kept patulous by the distended condition of the intestines.
2. Associated renal trouble, which alters the blood in some cases, rendering it less coagulable.
3. Marked organic heart disease. The blood being impoverished and lessened in quantity is propelled slowly and the tissues are consequently imperfectly supplied with blood. Under these conditions a hemorrhage from the bowel becomes the "last straw that breaks the camel's back."
4. Cases of hemophilia. The blood is so altered that there is little likelihood of its being staunched.

THE RATIONAL TREATMENT OF SUNSTROKE.

BY W. H. WEAVER, M.D.

CHICAGO, ILL.

That our treatment of insolation is almost entirely symptomatic is evidence that there is some point in the philosophy of its appearance or in the pathology which has been overlooked. Symptomatic treatment always means either incurability or ignorance of the diseased condition. Often in our haste to find relief for the sufferer we neglect well-known facts and principles. That there should have been 2,038 deaths from sunstroke during the month or August, 1896, and undoubtedly an enormously greater number of unreported cases of milder degree making partial recoveries, indicates, at least, that there is room for improvement in its treatment. Secondary fever and headache, with a low form of meningitis, incapacitates many men who have not been killed outright by the stroke.

Resulting from the rapid transpiration through the lungs, and surface of the body containing 2,800 sweat glands to the square inch, there is a great reduction in the volume of the blood, as if in an evaporator. With the perspiration is lost a large amount of sodium chlorid, but very little, comparatively, of the waste matters and impurities of the blood. The loss of sodium chlorid diminishes the acidity of the gastric juice and it soon becomes inefficient. The drinking of large amounts of water during the process of digestion further reduces the digestive power and weakens the muscular coat of the stomach, resulting in its dilatation and gastro-intestinal catarrh. The continued absorption of the products of incomplete digestion thus loading up the blood with waste matters assists in the production of toxemia. The kidneys are sluggish because of the diminished quantity of blood. The scanty urine passed is as heavily loaded as possible with waste matters and is strongly acid.

Considering all these important factors, and possibly more, the resulting condition would be that of heat stroke or thermal fever, with great injury to the nervous system in severe cases. This high percentage of toxins and waste matters in the blood must be rendered innocuous. Nature attempts to do it by burning it up with a high fever. But as nature's fevers often get beyond control if allowed full freedom, we prevent a disastrous result by reducing the temperature of the patient. At one time venesection, free and copious, was practiced in India with such fatal results that it was abandoned. By this means toxic elements were removed from the body, but the percentage in the blood remained the same or increased from the lower arterial pressure and the increased inactivity of the kidneys. However, there is one case of which I have read the report but have since been unable to find it, where the blood removed was immediately replaced by the normal salt solution, with rapid and complete recovery of the patient. This procedure effectually reduced the percentage of toxins in the blood.

I would propose the use of artificial blood serum (Cheron's), which is always ready and requires no preparation except the aseptic needle and operator. Its use should be continued until the normal action of the kidneys is established, and the temperature reduced to nearly normal. By this means we restore the two elements lost in large amounts from the blood as a result of excessive heat. The treatment of remaining conditions or complications should be based on accurate knowledge of their causes. Dr. A. Lambert read a paper before the New York Academy of Medicine, May 20, 1897, in which he says that "the theory best suited to our present knowledge is that it is due to auto-intoxication, with heat as a contributing cause." This, then, ought to be the basis for the scientific treatment of the condition in all its manifestations. The initial treatment should probably always include the immediate use of the ice-cap and bath for high temperature and unconsciousness. Still, some cases die with low temperature while many recover from temperature ranging as high as 110 to 115 degrees F.; so that high temperature is not necessarily fatal, and it may be that if the theory of toxemia is made the basis for treatment, a much larger percentage of cases may be saved and make more rapid and complete recoveries.

126 State Street.

ANCHORING THE KIDNEY.

Presented to the Section on Surgery and Anatomy at the Forty-eighth Annual Meeting of the American Medical Association at Philadelphia, Pa., June 1-4, 1897.

BY R. HARVEY REED, M.D.

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF SURGERY AND CLINICAL SURGERY, OHIO MEDICAL UNIVERSITY; SURGEON TO THE PROTESTANT AND UNIVERSITY HOSPITALS, COLUMBUS, OHIO.

The frequent occurrence of hydro- and pyonephrosis warrants our study as to their cause and prophylaxis.

Hydronephrosis is the result of an occlusion of the ureters. This may be due to a calculus, adhesive bands, tumors, or by a kink obstructing the lumen to such an extent as to prevent the flow of urine from the kidney to the bladder. Experimentation by the author and others, where the ureter has been ligated in the lower animals, has demonstrated that the healthy kidney will endure an enormous amount of torture without undergoing degeneration. Under these circumstances it has been demonstrated that hydronephrosis may exist from ten to fifteen days with the kidney greatly distended without a breaking down of its substance. Notwithstanding this fact a continuation of the pressure will sooner or later be followed by pressure necrosis and pyonephrosis.

It is not my purpose in this paper to take up the question of hydronephrosis or pyonephrosis caused by calculi, adhesive bands, pressure by tumor, or by tubercular or pus infection. I shall confine what I have to say on these conditions to the causes arising from the mechanical obstruction due to the displacement of the kidney and their relief. While the congenital displacement of the kidney may be followed by mechanical obstruction of the ureter. we are apt to have this form of obstruction arising from a traumatism resulting in a kink of the ureter at the point of obstruction, and if not promptly relieved it may be followed by permanent obstruction resulting in inflammatory adhesions followed by hydronephrosis, and if not relieved, by pyonephrosis.

This brings us to the point of how we shall best relieve this pathologic condition. We all know, as in an ordinary hernia, it may be temporarily relieved by taxis or change of position so as to replace the kidney and by doing so relieve the obstruction for the time being. But also like hernia, it is liable to return, and while the patient may live for years in this condition we never know the moment a permanent occlusion may occur which will place the patient's life in jeopardy. If this be true, then we are justified in performing a radical operation whereby the kidney shall be anchored as near its normal position as possible.

Experience has taught the writer that like pessaries and trusses, abdominal palliative treatment which usually consists in abdominal bandages and compresses is of little or no value. While these are advocated in out text-books, and have been resorted to by many practitioners, I am of the firm belief that their use is of little or no value in giving permanent relief. It is only necessary to go to the cadaver and examine for ourselves to see that a bandage can not be placed over the abdominal cavity with sufficient firmness to hold the kidney in place, for the reason if the bandage be drawn sufficiently tight to press upon the anterior portion of the spinal column itself, it would still leave the kidney free to move underneath the bandage beyond any question.

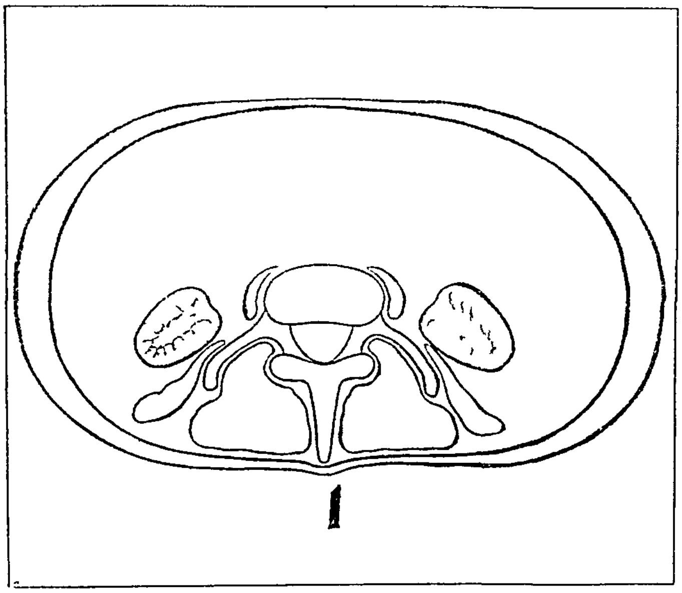

Diagram showing the relative relations of the kidney to the abdominal wall and the spinal column

A glance at the accompanying chart will aid in recognizing the fact that the kidney is so located, anatomically, as to be out of reach of general pressure made upon the abdominal cavity although that pressure may be of such a character as to press firmly upon the anterior and posterior portion of the spinal column. If this were done we all know that it would be followed by serious injury to the contents of the abdominal cavity, and to attempt to overcome this anatomic condition by the use of a compress would likewise be dangerous and useless.

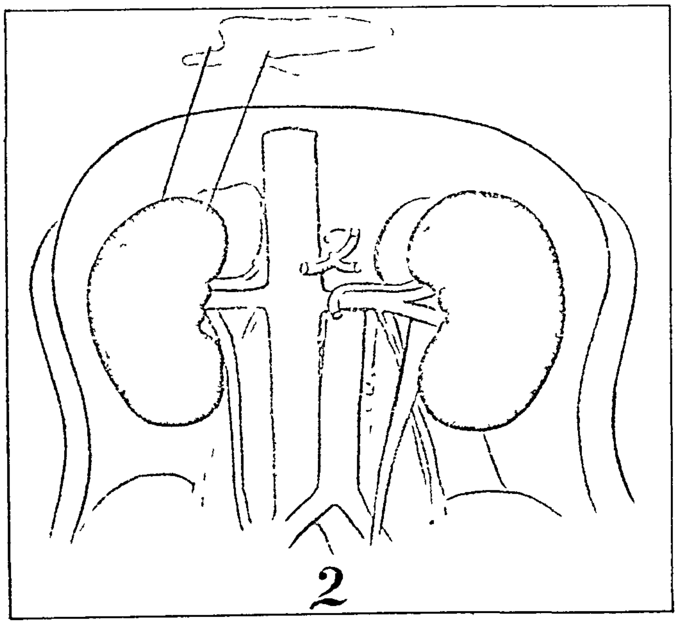

Diagram showing the insertion of the needles through the upper part of the kidney, one needle being inserted at a time.

I realize that there are objections to the radical cure of a floating or loose kidney, but I believe on the average, there is less danger to the patient who submits to a radical cure than to allow this condition to exist taking the chances of hydro- or pyo-nephrosis which is so apt to follow a chronic condition of this kind. The methods for anchoring the kidney, which have been handed down to us for ages in our text-books, entail difficulties which I have endeavored to overcome and, while this method contemplates the opening of the abdominal cavity, I feel justified in advocating this procedure under the present advanced stage of aseptic surgery especially when the method proposed is so much more simple and so much easier performed.

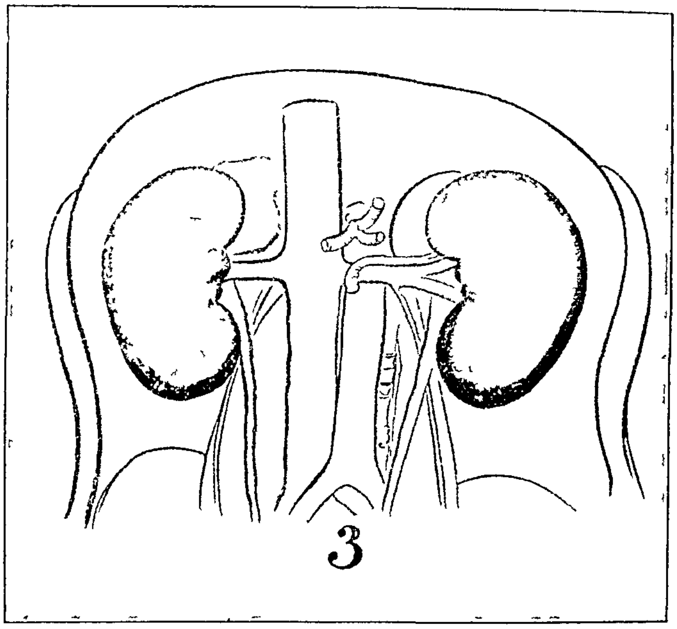

Diagram showing the anchor after it has been placed, as seen from the opening in the anterior abdominal parietes

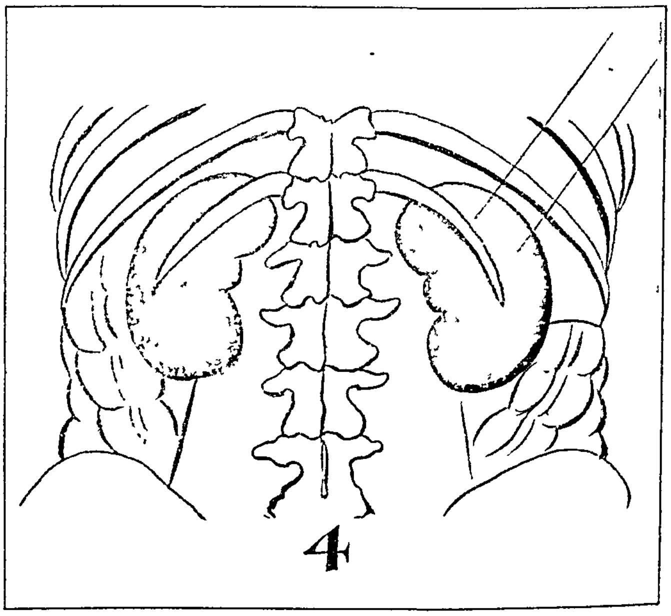

Diagram showing the exit of the needles posteriorly between the 11th and 12th ribs.

Notwithstanding the attempts at describing this method in previous papers, I feel that the description has not been clearly understood, basing the same upon the numerous letters I have received from members of the medical profession in different parts of the country. For this reason I endeavor to make this method more clearly understood by the accompanying illustrations.

In making this operation very few instruments are required. All that is necessary is a scalpel, two or three hemostats, a pair of small retractors and two straight needles which I have had made especially for this purpose, each one of which should not be less than six inches in length. These needles should be placed one at each end of a single suture which may be sterilized silk-worm gut, silk, kangaroo tail or catgut.

In making the operation a small incision is made in the abdominal wall over the normal position of the kidney. Usually this opening need not exceed two and one-half inches. The intestines are turned to one side and the kidney brought up or down, as the case may be, to its normal position, when the needles are passed through the cortical substance and brought out between the eleventh and twelfth ribs on the back. By referring to diagram No. 2, the position of these needles will be observed as they appear from the front.

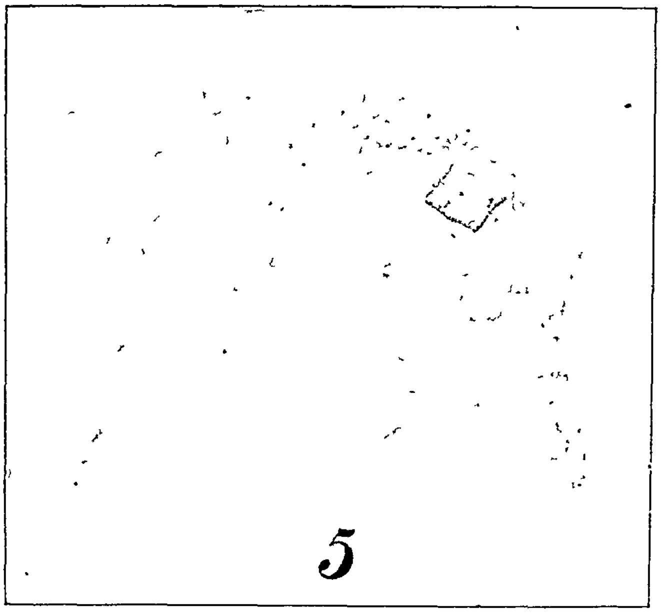

Diagram showing the ends of the anchor tied across a piece of gauze on the back, and the approximate position of the kidney.

Referring to diagram No. 3, the position of the suture is shown, as seen from in front, while plate No. 4 shows the approximate position of the needles as they make their exit posteriorly.

After having passed the needles through the kidney, the lumbar muscles and the integument, the assistant makes traction on them until they have passed entirely through all these structures. In the meantime the operator should place his finger under the ligature and by the touch satisfy himself beyond a question that it does not include a loop of the intestine. It should only include the peritoneal covering of the kidney and the kidney itself. He should also guard against drawing the suture too tight, but just sufficiently taut to hold the kidney in place.

The ligature should be tied over a piece of gauze (see diagram No. 5) to prevent unnecessary irritation of the skin. There is nothing left to do now but close the abdominal wound, allow the suture to remain from ten days to two weeks, when it can readily be removed, which leaves the kidney free from all foreign substance. If deemed necessary two or three sutures may be inserted, but I have not found it necessary to insert more than two in any case I have operated on, and in the majority of cases I have only used one, with the most satisfactory results.

In conclusion I would recommend:

1. The radical operation for anchoring the kidney rather than trust to the palliative treatment.
2. The use of the double spear or staple suture, as demonstrated by the accompanying illustrations, in preference to any form of lumbar operation.

DISCUSSION.

Dr. I. N. Quimby—I would like to report a case in which the kidney got loose some time after it had been anchored, and this was doubtless due to the inflammatory action which was set up. I must not speak against the bandage as I think it does much good by compression.

Dr. J. D. Thomas of Pittsburg—Putting a ligature on the far side of the kidney to bring it up against the back is a good method, provided you feel sure it will stay there. The bandage does not cure the patient but gives some comfort. A certain number of cases will necessarily relapse.

Dr. Reed—In comparing my method with that of Dr. Thomas I must say that I think it a very advisable one, although there are some objections. The principal one seems to me to be due to the fact that the surgeon does not always find the kidney just where it should be, and another objection is the time it takes. It matters not how you anchor the kidney, you will have the same difficulty in getting it where you want it and holding it there. In my method there is no slipping up or down of the kidney, and you have it fixed so that it can not move after the first suture is put in. The simplicity of my method is a great point in its favor. In any method we must have adhesions formed in order to have the kidney remain in place. I have never had any trouble with the operation and I hope that the gentlemen will be kind enough to try it.

ROENTGEN RAY SKIAGRAPHY.

Presented to the Section on Surgery and Anatomy at the Forty-eighth Annual Meeting of the American Medical Association, at Philadelphia, Pa., June 1-4, 1897.

BY DE FOREST WILLARD, M.D.
PHILADELPHIA, PA.

Professor Goodspeed has very properly emphasized the importance of the study of normal living anatomic delineations. Even surgeons are not familiar with the appearance of the living skeleton *in situ*, and for accurate comparison we assuredly require a series of skiagraphic normals.

I was in my first efforts greatly puzzled in the interpretation of conditions either plainly or indistinctly seen in the skiagraph, and even after considerable experience am obliged to study with great care each representation in order to differentiate the abnormal from the normal conditions.

Although skiagraphy is a most valuable assistant to the surgeon, yet a word of caution is necessary. It has been most conclusively shown that the position of the tube, the direction of the rays, the method and time of the exposure, the magnification of portions of an object not in contact with the plate, the elongation of shadows from distant portions of an object, together with other varied conditions, may so completely distort the resultant image that error is certainly possible. A fracture may appear to exist when a bone has not been broken; and on the other hand it has been shown that a known fracture produced by osteotomy is not discoverable. These facts make it imperative that the medico-legal value of these radiographs should be considered carefully, and pictorial evidence should receive only its due amount of consideration in connection with clinical evidence. Clinical evidence should have, and does have, large weight in the question as to results after fracture or other injury. Knowledge obtained by long experience and positive indications is far more valuable than any representation visible alone to the eye. A familiar example of this is seen in photography, an art which has obtained through many years a stage of great perfection, and yet representations taken by the same artist upon the same day of the same individual will yield results almost absolutely dissimilar; therefore, in suits for malpractice, while these skiagraphs may be useful, a single view is not indisputable evidence. The alleged deformity should be shown from a number of different points of observation, and comparison should be made with normal anatomic conditions. Recent callus is translucent to the rays and may appear falsely as a nonunion. Not only should the skiagraph be absolutely identified but all of the well-established rules of evidence should be rigidly followed.

Again, a simple deformity which does not interfere with function may not be of serious importance, and we have no right in the present state of our knowledge to compel a surgeon to secure results which were very probably unattainable under the conditions resulting from the particular form of injury or from environment. Valuable as skiagraphy is as an assistant to a surgeon, it is still a young science and its indications must be carefully and thoroughly considered in connection with clinical symptoms. A skiagraph is but one of a number of elements which will greatly assist a surgeon in arriving at a proper diagnosis and in the determination of the treatment to be employed.

FRACTURES AND DISLOCATIONS.—The importance of skiagraphy, particularly in fractures near the joints, is well illustrated by representations (shown on screen) which exhibit the difficulties in reduction and in retention of fragments.

For demonstrating fractures in the upper extremities the process is especially useful, and in hospitals where the patient can be taken to the scotoscopic room, the lower limb can also be readily skiagraphed. Doubtless an apparatus capable of transportation will soon be devised.

The progress of union in fractures can be steadily watched as the rays readily penetrate bandages, silicate of soda and even plaster-of-paris, although the latter contains lime. In non-union and in mal-union most valuable information can be elicited. In suspected dislocations where the local injury is great and the swelling considerable the advantages of this process are self-evident, and the necessity or non-necessity of operative interference is demonstrable.

In the present state of our knowledge, and with our well established clinical facilities for diagnosis, the securing of such deliniation, while very desirable, should not be considered an essential procedure, although frequently of great advantage.

In the difficulties surrounding injuries about the elbow-joint the assistance of anesthetics and the use of the rays will greatly simplify the problem.

The delineations of the thicker portions of the body are still only moderately clear; yet even fractures and dislocations of the vertebral bones, pelvis, etc., are recognizable.

In the skull the opportunities for misrepresentation are greater, but the difficulties will in time be overcome and the deadly and often undiscoverable fractures at the base may yet be made plain to our vision.

FOREIGN BODIES.—The detection of foreign bodies in the tissues is frequently a work of ease. Their location and depth is obtainable by pictures taken at different angles or by the device of comparative definition, such as has been shown by Prof. Goodspeed.

The locating of needles is still a problem (even though they are plainly visible in a skiagraph) since they are perfectly capable of being transferred from one position to another after the taking of the picture, and their habit of concealing themselves within the sheath of the tendons or of sliding in the tissues is well known. Many surgeons have missed a needle when it has been present in the direct area of operation. By taking views from different angles the relation to hard and soft parts can be determined with decided accuracy. Scott has proposed to take two pictures on different parts of the same plate; one end of the plate being covered with sheet lead while the other end is subjected to the rays; after which a second picture is taken on the other end of the sensitive plate without moving plate or tube. The varying angles of the object can thus be clinically determined or can be geometrically figured with accuracy (*American X-Ray Journal*, Vol. 1, No. 2, June, 1897, p. 41).

Two or three pictures taken at different angles, by tubes connected in series, will also give mathematical triangles for exact information.

Foreign bodies in the brain, esophagus and thoracic or abdominal cavities can often be thoroughly outlined, and by a series of rays even their depth may be located. With the fluoroscope also, a surgeon may during operation, especially in the esophagus, stomach or bronchi, bring to his help the immediate use of the rays and view and guide his instruments during manipulation.

A discouraging fact in the delineation of foreign bodies in the abdomen has been shown by Prof. Goodspeed in the case of the so-called "man ostrich" who had swallowed a large number of metal articles, belts, knives, etc., just previous to the application of the X-rays, yet only a darkened area was visible without any definite outline of the articles.

Drainage-tubes lost in the thoracic cavity are sometimes non-demonstrable, but after skilled adaptation of time of exposure are visible.

The placing of lead or other reference marks upon the surface to fix the location during skiagraphy is often of advantage in ascertaining distance from the surface. The process is also useful in locating the position of a collapsed lung in empyema and after thoracotomy, and the rapidity of expansion is not only interesting but an important addition to our knowledge.

BONE DISEASE.—The importance of the process in locating bone abscess, periosteal thickening, osseous growths, exostoses, etc., is undoubted and much information can be obtained, not only in regard to the shape, attachment, position, etc., but the question of treatment may be materially influenced.

JOINT DISEASE.—In joint disease, not only of minor articulations but in the larger joints, as the hip and knee, most important results are obtainable. Joint erosion of cartilage, destruction of the bone, etc., are as nearly visible to the eye as if the joint itself had been opened by the knife, and the question of excision, erasion, amputation or non-interference may be facilitated. Whether a joint should be allowed to remain anchylosed, or whether it will be safe to attempt restoration of motion can be very accurately decided by this process as I have previously exhibited ("Trans. Amer. Surg. Assoc.," 1896).

In hip diseases the non-existence of the head and neck of the bone, and the position and condition of the upper extremity of the femur can be readily determined. Old dislocations and fractures of the neck of the femur can be also shown with advantage.

In caries of the vertebra not only can the diseased area be located, but the outlines of the resulting abscess can be determined by withdrawing the pus and filling the cavity with iodoform emulsion, which will outline the thickened and darkened sides of the abscess cavity. In hip abscesses the same maneuver can be practiced.

In anchylosis of the shoulder great assistance can be gained by the simple representation. Osseous projections, nodules, callosities, etc., interfering with the restoration of the joint motion are readily shown. The process is also helpful in periostitis, in bone thickening and in demonstrating the cause of metatarsalgia. Epiphyseal separation can also be differentiated from dislocation.

In knock-knee, bow-legs, deficiencies of bone, irregularity of condyle growths, etc., the use of the process is invaluable.

In talipes the shape of the tarsal bones may be outlined and the form of operation decided upon (Willard: "Trans. Amer. Ortho. Assoc.," 1896).

In the foot, deviations of all kinds from the normal standard are demonstrable with the greatest ease and accuracy; and the same may be said of the hand.

Gall and Bladder Stones.—Gall-stones, renal calculi, enteroliths, etc., while decidedly opaque to the X-rays are frequently not discoverable when *in situ*. Their detection will largely depend on the skill of the operator and his technique. We have many things yet to learn in regard to outlining these abnormal bodies, but a few months will probably bring extended knowledge. The difficulties in the case of gall-stones are due to the fact that when surrounded by the medium of bile they are obscured. In renal calculi also close relation of the vertebral bodies and ribs may conceal the concretion. The different varieties of concretions require special care as to the time of exposure, etc. In the bladder, the bones of the pelvis also obstruct the view; but by passing the rays in the direction of the axis of the pelvis this difficulty may be overcome, as has already been shown in several instances.

It is scarcely necessary for me to speak of the advantages of this process in regard to the more strictly medical conditions such as aneurysm, dislocation of the stomach, the condition of the viscera, subdiaphragmatic abscess, etc.; or of its use in ophthalmology. Its employment is steadily advancing in importance.

Dangers.—The dangers following the use of the X-rays may be due to two causes. To an idiosyncrasy or to susceptibility to the ray's action; or as seems more probable to me from experience, the necessity for skilled knowledge on the part of the operator. In a large number of these skiagraphs, made for me by Prof. Goodspeed, I have never had the slightest difficulty, and the explanation of this seems to me to lie largely in the fact that Prof. G. keeps the tube twelve to fifteen inches from the body; while in the cases that have been burned I have known the tube to be placed only three or four inches from the subject.

Undoubtedly an inflammation extending to a suppuration or slow gangrene may be caused by too close application of the rays. This action is doubtless a disturbance of or an interference with, the nutrition of the part caused not by bacilli, but by an action akin to that produced by the chemical rays of the sun. Unfortunately the patient does not, as a rule, detect any special electric sensations, and only occasionally is the sensation of heat realized. The separation of the eschar is not unlike that of a burn, yet the action produced by these rays is probably one *sui generis*. The safe plan, therefore, is to allow for at least twelve inches between the skin and the tube during exposure.

PRACTICAL DIFFICULTIES OF PSYCHO-THERAPEUTICS.

Presented to the Section on Materia Medica, Pharmacy and Therapeutics at the Forty-eighth Annual Meeting of the American Medical Association, at Philadelphia, Pa., June 1-4, 1897.

BY G. V. I. BROWN, D.D.S., M.D., C.M.
DULUTH, MINN.

Last year, in a paper before this Section, I gave somewhat in detail a description of the various states of disordination accountable for psychic phenomena, designated by a variety of terms, significant for the present purpose by the possibility of their utilization in the department of therapeutics, and with this end in view I also cited a number of cases, illustrating beneficial results obtained in widely different affections by fixation of attention and suggestive therapeutics. At this time, therefore, I desire to eliminate discussion of elements of doubt and skepticism, together with confusion of terms and difficulties of definition that lead away from the practical side of the subject, and deal as directly as possible with the difficulties some nine years' experience have shown me must often be overcome to successfully administer this treatment.

In view of the fact that more or less wonderful cures have been effected through mental influence, why is not psycho-therapeutics more generally used? The answer must be not because of inefficiency, for efficiency in many diseases has been repeatedly demonstrated, but by reason of certain difficulties encountered in its use in daily practice, in the ability to overcome which lies the possibility of successful results. These may in a general way be enumerated as follows: 1. The almost endless variety of individual peculiarities among patients subject to functional neuroses. 2. Instability of impressions. 3. Counter influence of autosuggestion. 4. Increase instead of decrease of the most characteristic symptom, self-consciousness. 5. Danger of masking the symptoms of some organic disease until it may have progressed beyond curative interference, especially of a surgical nature.

At least a large proportion of patients requiring psycho-therapeutic assistance for nervous troubles are naturally of neurotic tendency, and though perhaps beyond all reproach with regard to mental unsoundness, are nevertheless so erratic and prone to peculiar notions, so flighty in the transmission and nature of their thoughts, that the individual equation becomes indeed a very uncertain problem, and to such natures this treatment often seems at [illegible] to be [illegible]ularly suitable. They will accept [illegible] [illegible]ual eagerness and for a time [illegible] remarkable degree, deceiving both themselves and the operator, as their imaginations play upon the fancied improvement. Yet, by reason of the very lack in brain development, imperfection of the nervous elements, or whatever the original reason of deficiency may have been, there will be in like degree a want of stability evidenced in the inability to retain permanently and beneficially suggestions given, and just as love sits lightly upon those whose affections have been transferred from one person to another in the course of numerous flirtations until its steady flame may have been utterly destroyed, leaving only the emotional reflection, so these patients who usually have passed from doctor to doctor, from remedy to remedy, as the history of their cases indicate, have simply been supplied with a new emotion, and in a little while the whole structure of hopefulness will collapse with apparently good results lost in despondency or given over for some new thing that they are about to try.

Among these are commonly the so-called subjects that hypnotists and mesmeric healers write about. Just as they tend to extremes in other matters, so in hypnotism they pass more readily into the deeper states, exhibiting catalepsy, strange actions and other phenomena significant of profound condition; yet, frequently, without nearly so deeply rooted a hold on their minds as will result from a healthful suggestion given to patients of another class who are not at all in a hypnotic state and who would not easily be put into that condition. Such cases are well adapted for description in books and essays, but for the practitioner with whom they continue to abide are most discouraging. In the treatment of this class one must place but little reliance on outward and visible signs of improvement. The operator must impress the fact that the process of recovery will necessarily be a slow one, and have himself understand that long, patient and continuous effort will be necessary to stimulate the development and strengthening of the weakened nerve elements and to overcome the habit of disease.

Another class, frequently the outcome of characteristics before described at an early stage, have abnormal hopelessness about their condition; look with skepticism on what they call theories and with every appearance of desire to further beneficial influence, have an inherent degree of obstinacy, the common associate of nervous disorder which sets up an almost insurmountable state of mental opposition. Often they seem anxious to get well. They frequently make an earnest effort to co-operate and facilitate the mental influence, yet will betray in some unintentional way the fact that there is a clearly defined idea in their minds, an auto-suggestion, that you will not succeed, with a certain inward satisfaction to themselves, unreasonable as it may seem, when they believe you do not accomplish the intended result. When told to sleep they resist the influence, though the eyes be obediently closed, and at the moment when they ought to slumber will open their eyes, usually with a peculiar smile that at once tells the story and explains the cause of the difficulty, yet in all other ways such a patient may be and commonly is quite open to the effect of suggestion. Therefore, to manage successfully one must either continue some method of concentration until physical or mental weariness shall overcome the resistance, induce some influence sufficiently poweful to effect the same result, two sometimes difficult things to accomplish; or must, as I prefer to do, seem to put great etress on sleep or some other suggestion which is understood by the patient to be significant of hypnosis or of susceptibility to your influence, but which is really of minor importance; and while the attention is thus fixed upon resisting this particular effect the best possible state of susceptibility is opened for other suggestions, which being incidentally given will usually show a surprisingly happy result. For example, a neurathenic patient may require rest and yet resist the direct effort to induce sleep, but if told that sometimes patients can not be put to sleep by merely being told to sleep and that in such cases generally a drowsy feeling comes on at a later hour, almost invariably such a patient will leave you filled with the idea that you could exert no great influence over him, yet will tell you later that he felt drowsy and fell asleep at about the hour you had indicated.

In almost every instance by the use of some simple expedient such as giving instructions to take a series of twenty full regular inhalations and exhalations, resting for a short period each time the given number is reached, or, better still, by massage one can assist the direction of attention as desired and avoid mental opposition in a great measure. Self-consciousness is the active irritant in neurasthenia, to the hypochondriac and to sufferers from disorders of nerve and muscular action.

It seems to be a simple matter, as described by a host of writers, to divert the mind into other channels; yet, as a matter of fact, it frequently taxes one's ability to the utmost to do this so-called simple thing. Since the very effort at concentration of attention will usually take its most accutomed form, thus increasing consciousness of trouble and, as has frequently happened in my own experience, methods of assisting mental control, successful in other cases, have quite unexpectedly caused in a few moments violent outbursts of weeping on the part of the patient or a hysteric condition quite beyond control for the time being.

One such patient described her case recently by saying, "it makes me pity myself." Usualty a gentle stroking of the head without trying to make noticeable suggestion for a time will do more to restore the natural equilibrium temporarily upset than anything else, while extreme patience and infinite tact must do the rest later on.

The very nature of this treatment, tending as it does to give hopefulness and encouragement, successful as it should be in relieving pain, reducing temperature and giving relief by allaying symptoms by which nature expresses to us the warning of disease, if, in reality, the condition be one of organic nature, despite the claims of Bernheim and others that organic changes can be accomplished in a state of deep hypnosis, its reliability could hardly be compared to the surgeon's knife, and if an early operation would otherwise have been called for, then how serious might be a treatment which by masking symptoms has delayed instead of facilitating diagnosis.

In conclusion: All of the difficulties described might be summed up into one general head by saying that the chief disadvantage of psycho-therapeutics in general practice, aside from the consideration of the possibility of danger of weakening mental influence, causing too great a susceptibility and becoming a factor in crime, which does not lie within the province of this paper, is the practicability of individualizing each particular case, and just in proportion as cases may be studied and treated with due recognition of individual requirements, so will also be the record of successful results.

A NEW METHOD OF INVITING SLEEP.

Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY J. B. LEARNED, M.D.
NORTHAMPTON, MASS.

A violent collision with the frozen earth, the result of my first drive with a newly purchased horse in 1880, took me out of the busy life of the every day and night practitioners. For many years, instead of experimenting upon a willing and paying class of the laity, I was experimenting upon an unwilling and non-paying member of the profession. I did not sample all the remedies of the "Dispensatory," but I sampled many remedies outside the "Dispensatory." Hot water, cold water, inside and out; lack of food and surplus of food; gymnastics in my room and gymnastics with the woodsaw in the basement in the night time, brisk walking in the halls and around the square before retiring, friction direct and indirect, long deep inspirations with and without the numberless mental occupations, as varied as the physical; all these I tried faithfully. I also read about insomnia, its causes and remedies It was during this blank interval, while I waited for power to return to me, that I raised the inquiry: Can we devise any means to turn off the belts from this little fragment of brain that insists on its automatic excursions day and night—this perpetual motion of a few cells of gray matter, that obstructs rest and prevents repair of the great whole? Can we by counteraction set up a motion elsewhere after retiring, that will bring an equilibrium of arterial and vital current so that sleep will come to our relief?

During this frame of mind, I experimented and practiced with muscle and will in many and divers ways after retiring: I had the whole bed, length and breadth. I directed various contractions and relaxations, and finally reached the conclusion that a systematized and well ordered method of muscular and mental activity would soon bring the conditions required—a sense of fatigue that precedes and invites sleep. A recumbent position furnished the best opportunity. Once asleep the point is gained. Who has not been dull and almost asleep before retiring, but wide awake immediately after disrobing and experiencing the gentle shock of the fresh sheets and changed posture?

Is it necessary to recite here the advantages of proper conditions of atmosphere and temperature of the sleeping room? I will assume not, but will say that open windows at all seasons, heat never turned on in my sleeping room and moderate bed-covering has come to be a necessity with me. This is my method:

Lying upon my back, with or without pillow, I reach for the foot-board and head-board at the same time. This brings into use many muscles that have not been on active duty during the day. I now raise the head half an inch, enough to realize that it has more weight than I first supposed. At the same time, by will power, I direct the respiratory process to a slower and deeper movement. I order about eight inspirations deep and full, in place of sixteen per minute. Every inspiration is recorded, counted. Thus the process begins of inviting the forces into new channels and relieving the old. At the expiration of ten to twenty inspirations the head has become so heavy you want to drop it. This you do. Immediately the right foot is raised a half inch from its resting place. The reach for the foot-board and head-board continues; the count of slow deep inspirations continues; the sense of fatigue of muscles engaged in lifting the foot and holding up the coverings continues. Here, as before, the foot, like the head, has become a dead weight and must go down. Now, immediately the left foot is elevated with all the previous conditions remaining. The reach downward and upward of foot and head is kept up, so far as power will permit without exhaustion. This foot remains up for the same length of time, the respirations being the clockwork. It goes down. You may now relieve the reach for foot- and head-board and use the muscle to elevate the trunk, holding it by resting upon heels and head and shoulders. This elevation of the central part of the body and rest upon the two extremes will call for change as all the former positions have done. By the same clock you have the time marked off and the body is again flat upon the back waiting new orders. Turn now to the right side reaching for head- and foot-board as before, and elevate the head half an inch by use of the lateral muscles of the neck and chest. At the expiration of the time the head goes down and the foot goes up by use of the lateral muscles. Change now to the left side and repeat what has just been accomplished by the muscles of the opposite side. You have now assumed eight positions and used a large majority of the whole number of muscles in carrying out your dictations. If you have not fallen asleep before this cycle is completed you may begin again and go over the same round. If you have already gone to sleep you will not be required to.

Other methods of procedures would answer the same purpose, undoubtedly, with the respirations guarded and uniformity observed, mind and muscle constantly occupied. There should be no periods of rest, no vacations. Thus fatigue comes inevitably and sleep follows. I know of no means so ready, so much at command, any time and anywhere, so inexpensive and so absolutely certain to induce sleep as this routine of mental and muscular exercise. It involves a principle. Following it, sleep appears to be inevitable. There is but one drawback; it requires some exertion, continuous mental and muscular exertion. The indolent will find it unattractive.

Some conditions of heart or nerve center may altogether contraindicate this method. The length of time employed in the several positions will vary according to the make-up of the individual. No one rule can apply to the robust and the exhausted as to the time spent in a given exercise, only that which measures the power of endurance. It is the sense of general weariness following persistent effort that brings the desired result.

DISCUSSION.

Dr. **Eccles**—I have been something of a victim to insomnia myself, have tried all sorts of plans and have studied, as far as I could, the causes of the trouble. Confining myself to my own experiences, I have observed that fear is the cause of insomnia with me. No matter how fatigued I may be on retiring, if the fear that I will have a sleepless night takes possession of my mi [illegible] able to sle [illegible] long as I have the fear no [illegible] good, [illegible] I get rid of this fear I can get to sleep. Anything that will divert the mind will accomplish this.

Dr. Woodbury—Any method which will take the place of reliance upon narcotic drugs in the treatment of insomnia should be heartily welcomed. In some cases a small amount of food, such as a glass of hot milk or a cup of broth, or even heavier food does all that could be wished. Dr. John L. Atlee, once President of the Association, told me that he used to suffer greatly from insomnia and had tried all the remedies that had been suggested to him; finally he found that by keeping a supply of water crackers in his bureau drawer, and when he could not sleep, getting out of bed and eating a couple of crackers while walking about the room would always enable him to get a good sleep when he went back to bed.

Dr. J. V. Shoemaker—There are times when not only the method which has been suggested by the reader of this paper will fail, but also when every other agent will fail, including the use of food and mental influences. It depends on the mental constitution of the patient what drugs or what influences may produce sleep. It has been my preference for several years to teach the use of other means in the place of hypnotics as a method of inducing sleep, on account of the great abuse of these drugs at the present day. At the present time the literature of medicine is filled full of new hypnotic agents which are recommended for the doctor to use. As I said before, these gymnastics will fail in some cases and succeed in others. I remember a case of a gentleman who had tried everything without success, including the use of food or hot milk, electricity and massage, mechanical movements and the modern hypnotic agents, but all failed to relieve his insomnia. I traveled with this gentleman, very much against my will, as he prowled around during the day complaining of his inability to sleep at night. We happened one evening to go into the great garden of Strauss in Vienna, and as the strains of music reached our ears I noticed for the first time an expression of tranquility on the face of my patient. That night he had a good refreshing slumber for the first time for years. What I want to illustrate by this case is the fact that different cases require different remedies. This was a patient who failed to receive benefit from massage, electricity, modern narcotic remedies, but in whom music accomplished the desired result. I believe that out of the multitude of narcotic remedies offered at the present day, there is not one which can be relied upon to positively succeed. One will succeed in one case, another in another. In ordinary cases taking a little food, in others applying mustard plaster, or as the old ladies used to say, "to tie onions to the wrists and feet would bring it about." So in regard to the suggestion made in the paper, I would say that in many cases it would succeed, but there are others where other agents or methods must be used.

Dr. Anderson of New York—The method calls to my mind Dr. Benwill's method of inducing anesthesia by rapid breathing, and it occurs to me that the result may be attributed to the accumulation of carbonic acid in the blood.

Dr. Learned—The method I advocate is not simply a means of producing muscular fatigue, because I have often been very tired and still suffered with insomnia. As regards the carbonic acid explanation, I would say that I only reduce the respirations to the normal rate during sleep, and there is no such accumulation of carbonic acid in the blood as has been suggested.

A NATIONAL MEDICAL SCHOOL.

Presented in the Section on State Medicine at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY ALBERT S. ASHMEAD, M.D.

NEW YORK.

A wolf in sheep's clothing could not be more dangerous to the shepherd's fold than the enemy which confronts the general body of practitioners today. Accumulation of wealth in a few men's hands and the drifting of these men to the cities, is one of the causes which render the endowment of medical schools, the founding of hospitals, easier than ever. The medcal schools will obtain from rich men money to build Smith clinics, Jones maternities, or Robinson hospitals or operating wards. In the expenditure of such funds, the medical man who obtains the superintendence ceases to be independent; he becomes, as a rule, the retainer, if not the sycophant of the rich man.

In times of yore a student starting the study of medicine appeared at college, after having read with his preceptor, a general practitioner in the country, for from one to three years. Today preceptorships have ceased to exist, otherwise than nominally. The student only starts his studies after coming to the college, and usually drifts at once into a specialty. With a compulsory four years' course in our medical schools has come the demand for academic degrees before matriculation. Such men after graduation are not likely to settle in the villages and be satisfied with general practice; the majority of them will wish to settle in the cities and try specialties. The country practitioner will go entirely out of existence, or if he does survive, he will fall into contempt as a failure as an educated man. Hospitalism and specialism are enemies of general practitioner work.

Should an immoral or otherwise unworthy man apply to any of our schools for matriculation, is there one of these schools (in the absence of direct charges) that will refuse to matriculate and graduate him? Not one. I know a school, one of the most eminent of the schools, which had among its third course students (it was a college requiring three years attendance) a man who had committed an abortion, a fact which was reported to the president of its alumni association. When this student came up for graduation he was conditioned on two branches; when he came up again he was again conditioned. Then he went to a rival school, took out a course of tickets, was put on the *ad eundem* list, and soon afterward graduated. This man is today practicing in New York City, and holds a position on the staff of a prominent hospital.

Rivalry will increase with the needless multiplication of our medical schools; only rivalry here will do quite the contrary of what competition does in other branches. It will simply be detrimental, as the above instance shows.

Is there a legislature in any State of the Union which will refuse to charter a new medical school if the application is backed up by reputable medical men and money? Not one! They do not ask whether the supply keeps step with the demand.

We have too many medical schools. The student who fails to graduate from the high standard school has only to fall to the next level to obtain its degree.

The salvation of the general practitioners of America is in the formation of a National standard, or a National school, and the taking away from the State the chartering of the medical schools. Let us have one medical school which will graduate general practitioners for the country. It is the country practitioner who needs protection against city specialists.

Let us revive the method to require for each student the old-fashioned preceptor, who stands sponsor for the fitness and moral character of the applicant for immatriculation, who when the candidate applies for graduation will certify that his fitness and character are still the same.

There were, though not for medicine, such preceptors in Old Rome; every patrician was a lawyer, and received in his study the young man who wanted advice. This study was a kind of law school, and a school of morality and of general practice of life. It was his duty to

Clienti promere jura
Majores audire, minori dicere per quae,
Crescere res possit, minui damnosa cupido.

SURGERY ONE HUNDRED YEARS AGO.

AN HISTORICAL STUDY

BY DR. GEORGE FISCHER.

DEDICATED TO THE GERMAN SURGICAL ASSOCIATION.

TRANSLATED FOR THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION BY CARL H. VON KLEIN, A.M., M.D.

(Continued from page 591.)

XIII.—GERMAN MEDICINE.

Leibnitz; University of Halle; Thomasius, Wolff, Franke; System of Medicine by Hoffmann and Stahl; Boerhaave; Haller; Gaub; Vienna School: van Swieten, de Haën, Störck, Stoll; Neurologic pathology, Unzer; Humor pathologists Ch. L. Hofmann and Kämpf; Classification of diseases; Study of the ancients; System of J. Brown; Realization of Chemistry and physicians; Special pathology; Remedies; Medical practitioners.

When the German churches announced the eighteenth century, a warm, quickening spring sun shone in Hanover and Halle, newly vivifying the German sciences. *Leibnitz* there created German philosophy. He taught the Germans to think independently and to develop their sciences philosophically. Here were professors of the young University, who, as leaders in the movement, restored the mother tongue to scholars, made the ideas of the great philosophy popular, aroused the flat crude Protestantism and revolutionized German medicine. Leibnitz unified the inexhaustable depths of mathematic, philosophic, physical and historic knowledge. with a strong creative power and a depth of spirit through which he received the greastest influence upon his time. And the more because he was no learned Philistine, but a man of the world who understood how to lift science out of the student's dingy room and introduce it to higher stations, even into the salons of the emperor and empress, and to foreign nations. By numerous monographs and an immense correspondence he brought his weight to bear especially upon the leaders of the nation, breaking precedents on all sides. The point of his philosophy lay in the atomic doctrine which maintains the existence of simple indivisible substances from which all combinations are made up, a doctrine which is important also for medicine. The University of Halle, through the acquisition of several eminent, and some persecuted professors, had become a brilliant center for the development of German culture. The intolerant Leipzig theologians had accused the jurist, *Christian Thomasius* of heresy, on account of his candid teachings, and had driven him from Leipzig, whereupon he, with several hundred students, withdrew to Halle which in consequence of his great reputation was raised to a University (1694). At that time German scholars wrote in Latin, because the mother tongue, enriched with foreign words, appeared to them too rude and unyielding to intelligently express scientific matters. While they forced German thoughts into the dead languages, they hindered every national development. Indeed Leibnitz declared the German tongue completely ripe as a learned language, but he himself wrote almost entirely in Latin and French. On the other hand the intellectual and facile Thomasius, one of the brightest men of his time, who gave the death-blow to prosecutions for witchcraft, earned the great merit of being the first to give lectures in the German tongue in a German university (Leipzig, 1687). This threw the wigs of his colleagues into violent commotion, but greatly increased the number of his students. He contended in the press as the first journalist. At his side lectured the philosopher *Christian Wolff*, who had been driven from Halle by the orthodox party, and later had been reinstated by Frederick the Great. He collected Leibnitz's ideas into a system and as a clear conservative teacher, systematic and methodic, he smoothed the way in all the sciences and immensely expedited their promulgation in Germany. He frequently wrote in German. It is owing to the stimulus of these three men that, from that time on, the German language was more widely cultivated and triumphantly installed beside the Latin tongue, and was more frequently used in scientific works, although it could not entirely supersede Latin and, with scholars of the second rank, to the end of the century remained stiff and even crude. Nevertheless, this glorious achievement was the first step toward placing the whole nation in an entirely new relation toward the scholars. The three faculties in Halle had, in the persecuted theologian *August Hermann Franke*, who had been driven out of Leipzig, a worthy contemporary of Spener; these two restored intellectual freedom and the religious spirit to the dead letter of the torpid Lutherism. It was not their fault that this afterward worked so much harm as degenerated pietism, and indeed reacted upon medicine. The clerical life of which this university was the scientific heart, could not remain without some inflence upon the development of one young student in Halle who, together with Sebastian Bach, gave a magnificent impetus to German music through his grand oratorios, viz., Händel, the composer of the Messiah. Halle had also within its walls the two most celebrated physicians of Germany, *Friedrich Hoffmann* and *Georg Ernst Stahl.*

In the restless ferment which manifested itself in all sciences at the beginning of the century, German medicine did not remain behind, but went astray, however, when instead of seeking to enlarge its separate branches by exact investigations, it sought its advancement in the building up of systems. Theories stood everywhere in the foreground, and book-knowledge was supreme. They contended with beautitully worded repetitions, compiled the opinions of the authorities, and thereby overlooked the simple facts. The eighteenth century swarmed with systems into which the whole of medicine was fitted by force; one encroached upon the other and sought to crowd out its rival. The life of each varied according to the intellectual capacity and the social station of the author; now one disappeared when scarcely born and again another exercised its dominion for a decade and continually won new adherents. Nothing could be more welcome to the lazy practitioner than that he should be relieved of the inconvenient business of thinking. He had now nothing more to do at the sick-bed than to determine the chief character of the disease from the most prominent symptoms, whereupon his system placed in his hands the appropriate remedies, in black and white.

The two leading systems, one of which found the greatest acceptance in Germany for over a half century, were originated by Hoffmann and Stahl. These men were of the same age (born 1660); the former a physician in Halberstadt, the latter court physician in Weimar, when at the foundation of the University in Halle they were appointed professors in medicine. *Hoffmann*, who had [illegible] stud[illegible] mathemati[illegible] anatomy, physics, [illegible] and [illegible] medicine. He w[illegible] [illegible]se re[illegible] was widely extended not only as a writer but as a practical physician, insomuch that the famous Boerhaave, to whom the king of Prussia had applied for consultation, referred him to Hoffmann. For forty-eight years he taught in Halle, where he had founded the Medical Faculty and was the recipient of the greatest applause. He was at different times, for three years, body-physician to King Frederick I., but his residence in Berlin had made him disgusted with his colleagues. He was highly honored up to the time of his death (1742), and was the pride of the University. Hoffmann possessed a masterly eloquence, which brought professors and noblemen to his lectures, and he wrote in a clear, smooth, almost popular style. Although he highly prized the classic writers, he avoided all unnecessary learned citations in his numerous writings but, on the other hand, sought to give them a greater charm by introducing glimpses of other sciences. From his assertions, which he often premised without proof, he knew how to draw conclusions which followed one another with great clearness and in mathematic sequence, and which were all the more convincing and received all the more applause because they concurred with the philosophic ideas of his friends, Leibnitz and Newton. Nevertheless, he desired that all demonstrations in medicine should be either anatomic or physical, and considered that perfect proofs were possible only through the application of mechanics and hydraulics; he regarded the opening of cadavers as indispensable and made many meteorologic notes in order to elucidate the causes of disease. Yet his most important physiologic principle was an hypothesis. In all nature he assumed the existence of an æther which is also the most essential material in the human body, is of the most refined volatility and causes the movements of the organs. In the brain, especially, the æther is separated out of the blood and thence flows through the nerves into all parts of the body. The latter was to him a machine which works "according to laws of the higher mechanics, which are yet to be discovered." Life depends upon the continued movement of the heart and of the arteries, and the circulation of the blood is the origin of the warmth, nourishment and growth, and of all actions. Hoffmann considered every disease as a fault in this movement; if it was too strong there arose cramps, if too week, there followed atony; in the category of cramps, he placed fevers, inflammations, catarrh and diarrhea. From atony he educed all chronic diseases and also dizziness and plethora. The last named he considered as one of the most frequent causes of disease, aside from the air (of swamps and coal gas), the moon and the planets. Every fever arose from a cramp which drove the blood from the outer parts to the inner and in a similar manner caused inflammation, when the cramps prevent the blood from going to certain parts and forcibly drive it to other parts. One of the most frequent inflammations is that of the stomach, which is often mistaken for something else. His therapeutics were based upon the eradication of the cramp and atony. Few remedies but strong ones, was his motto, and he believed himself able to contend against all diseases with ten or twelve remedies. The acute cases he treated with cooling applications as Hippocrates, toward whom he also assumed a critical attitude; in chronic cases, wine, camphor and, contrary to Stahl, quinin and iron were his favorite medicines. Mineral waters, which he assiduously investigated, warm baths and dietetic treatment he prized very highly, but on the other hand, he was exceedingly cautious with opium. His name has been preserved to our day by the so-called Hoffmann drops, the elix. viscerale.

Stahl taught in Halle, whither he had been called by his friend Hoffmann. His branches were botany, physiology, pathology, dietetics, pharmacology and medical institutions. The two were colleagues for twenty-two years, until the increasing popularity of Hoffmann caused an estrangement between them and Stahl, in 1716, went to Berlin as court-physician, where he died in 1734. He was the deepest thinker among the German physicians of his time, but was gloomy, inclined to melancholy and superstition, and a pietist. He possessed boundless pride, which led him to say: "By the grace of God I know what I write." He could brook no contradiction and could not tolerate the successes of his colleague, whom he often flatly opposed. Like Hoffmann, he hated learned citations, but did not approach him either as an orator or a writer. His style was incorrect and prolix; his ideas often obscure and scarcely intelligible. Himself an eminent chemist, insomuch that he is regarded, together with Boerhaave, as the founder of scientific chemistry, yet considered this science as well as physics and higher anatomy as absolutely useless in medicine. On the contrary, he attached the greatest importance to facts, and indeed to the every-day, not the rare, fact which should lie at the bottom of theories. To him the most important thing was to discover the principle and the final cause upon which all forces and movements depend. His fundamental doctrine was that the body, as such, possesses no power whatever to move, but is controlled absolutely by the soul. It directs every movement and impels every process of the body, although it acts without consciousness and without consideration. Rejecting all mechanical ideas, he made the soul the principle of medicine, and with this conception he carried out his system with inflexible consistency. Leibnitz opposed him, saying that the soul can not govern the body independent of mechanical laws. Disease is a movement of the soul, while it, always watchful for the maintenance of the body, counteracts the causes of disease; movements arise from which the disease is composed. According to Stahl and also to Hoffmann, excessive blood is one of the most frequent causes of disease. It is best relieved by blood-letting, as menstruation and hemorrhoids prove, which latter is a wholesome regulation of nature and a remedy for the plethora of the abdomen. Fever was also considered a movement of the soul, which is designed to render unwholesome the feverish irritation which lays hold of the body and to separate it from the body. Even cold is a movement excited to expel the causes of disease, hence fever is often even beneficial to the body. Stagnation and congestion were distinguished from one another. The latter drives the blood so violently into the smallest veins that it stagnates because it can not move freely and easily. While, by this obstruction, nature is driven to even more intense vital movements and inflammation arises. Stahl declared that the vital movements of nature are sufficient for the cure of disease, and therefore considered that the all too great activity of the physician was injurious; he should be the servant of Nature, observe her duty, and then, when he sees the vital movement regular and powerful he should not destroy these wholesome agencies. One must follow the beck of Nature in fevers, which she, for the most part, cures by excretion, therefore the suppression of it should be avoided; hence quinin is injurious. In acute cases he recommended blood-letting and salts, and was an enemy to all powerful remedies (iron, opium and stimulants). In chronic cases he preferred laxatives, aloes, rhubarb and jalap. Like Hoffmann, he sold and extolled several secret remedies, especially balsam pills.

The third who exercised a considerable influence upon German medicine in the first half of the century was the most renowned teacher and the most celebrated physician in Europe, *Hermann Boerhaave* of Leyden (1668–1738). At first designed for the church, he pursued philosophic studies and much mathematics, which at that time was considered the basis of medicine. He maintained himself by giving instruction in these branches. Afterward he was made doctor of philosophy, and through his study of the works of Spinoza he drew upon himself the hatred of all orthodox people, so that the path to the pulpit was cut off from him by the doubt concerning his faith, and he gave up theology and turned to medicine, which he studied almost without a teacher. In 1701 he became lecturer on theoretic medicine in Leyden, later assumed the professorship of botany and chemistry, and in 1741 became director of the Hospital. There he was one of the first to offer clinical instruction, which was at that time still lacking in German universities. His eminent talent as a teacher, his vivid eloquence, the clearness of his lectures, which, contrary to the custom of that time, he gave entirely free, as well as the practical usefulness of his doctrines, soon gained for him a European reputation. Numberless pupils flocked to him from all countries, whom he knew how to inspire with his enchanting personality and his tireless activity for science. No lecture room was large enough to hold them all. So great was the pride of every one in being his pupil, so heartfelt the love of his fellow-citizens, that they illuminated the city when he recovered from an illness. His fame as a physician was unexampled. The whole world consulted him; Peter the Great remained a whole night in a carriage in front of Boerhaave's house in order to speak to him in the morning before the beginning of the lectures; a Chinese mandarin wrote "to Boerhaave in Europe." In spite of all deifying, he retained a rare modesty until his death. Indifferent to all external display, always in the most ordinary clothing, he lived as the simplest citizen and filled his leisure hours with the playing of the lute. "For thirty years he was the medical oracle of the European courts, the idol of his hearers, the object of veneration of the whole literary world, and in spite of his munificence to the poor he left his only daughter more than two million guilders." Haller said of him: "Some indeed, though few, attained to his learning; no one to his godlike, benevolent spirit that wished well to his enemies and those who envied him, and would not belittle even those who opposed him daily." Boerhaave did not arrange his doctrines into a system, but in Aphorisms and Institutions, which were received with extraordinary applause. The simple observation of nature stood uppermost with him, hence his veneration for Hippocrates and Sydenham, though he did not join many of his contemporaries in their one-sided enthusiasm for antiquity. Without prejudice, he took the best wherever he found it, unmindful as to whether or not it coincided with the theory. So, as a selector he created a medicine which, without rigorous consistency, had indeed no important ideas, but proved its value by the sick-bed. He rejected one-sided mechanical elucidation and mathematic demonstration in practical medicine. With his great services in the development of chemistry, it is to be noted that he conceded to it no dominant place, but only that of an auxiliary science to medicine. He first undertook the chemic analysis of urine. Diseases attack either the solid or the liquid parts, which latter soon become acid, alkali or viscous, and the simplest frequently occurring disease is the obstruction of the channels which contain fluids. He regarded inflammation as the stagnation of the red blood in the smallest arteries. Fever, in which he had already employed measurements of temperature, he thought a quick action of the heart with increased resistance of the capillaries, and at the same time the effort of nature to ward off death. Chronic diseases arise in part from defects in the fluid parts, and he distinguished seven kinds of dyscrasia: A sour acidity from which arise diseases of the stomach, acid eructations, sour milk, constipation, pustules, sores, etc., and should be treated with a vegetable diet, exercise, and diluent and absorbent remedies. Then a bitter and an aromatic fat-acidity, an oily and a salt acidity, an alkaline and a glutinous condition. Under these seven heads he classified chronic diseases, of which scurvy was the one he preferred to treat, and he applied to it the specified remedy, which was usually very complex, but sometimes was simple.

The mechanico-dynamic system of Hoffmann, the psychic system of Stahl, and Boerhaave's doctrines, contended in Germany for the honor of the day. The great mass blindly followed these men, to whom a genuine piety was common; it thought only what they thought and was divided into just so many sects. Hoffmann had a large following at home and abroad, especially as his system agreed with Boerhaave's views. The crowd walked by the side of these two men. The error lay in the training of mathematic practitioners who philosophized so subtly concerning the human body that nothing was left but a mechanical and hydraulic machine. Formerly one had to be an astrologer if he would be a physician; now everything in physiology is reckoned algebraically. This mathematic sect was the proudest, for they believed that by their method medicine was given absolute mathematic certainty. The later expression of Schlözer applied to them: "No nation in the world has been snatched from barbarism through mathematics." Stahl's doctrines, which aside from Hoffmann found a great opponent in Haller, were not understood by the majority because too deeply grounded for their time, and they were enthusiastically proclaimed almost wholly by limited intellects and pietistic physicians.

Such was the condition of theoretic medicine when, in the middle of the eighteenth century, the dominance passed to Boerhaave's greatest pupil, Albert von Haller, who, with his doctrine of irritability, gave a new direction to medicine. Boerhaave had the rare fortune to find a whole line of excellent pupils who, throughout their entire lives, adhered to him with the greatest devotion, and although some of them were far more illustrious than he himself, throughout many years they brought out new editions of his works with comments. Of his best pupils Haller and Gaub followed rather his dynamic and theoretic direction, van Swieten and de Haen the practical and the humoral-pathologic.

The Medical Colleges of the United States.

In accordance with the custom of the JOURNAL, to make one number each year largely an "educational number," the Editor recently addressed a circular letter to the Secretary or Dean of the Medical Colleges throughout the United States, requesting them to furnish the JOURNAL with a brief announcement of their college, covering length of term, fees, hospital and clinic advantages, etc.

The responses as presented contain much information, to the student and practitioner alike, concerning the trend of medical education throughout the United States.

ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

The Association of American Medical Colleges requires for all members that candidates for matriculation will be allowed admission, and subsequent graduation, subject to the conditions prescribed by Article III of the Constitution of the Association:

ARTICLE III.

SECTION 1.—Each college holding membership in this Association shall require of each student, before admission to its course of study, an examination the minimum of which shall be as follows:

1. In English, a composition on some subject of general interest. This composition must be written by the student at the time of the examination, and should contain at least 200 words. It should be criticised in relation to thought, construction, punctuation, spelling and handwriting.
2. In Arithmetic, such questions as will show a thorough knowledge of common and decimal fractions, compound numbers and ratio and proportion.
3. In Algebra, such questions as will bring out the student's knowledge of the fundamental operations, factoring and simple quadratic equations.
4. In Physics, such questions as will discover the student's understanding of the elements of mechanics, hydrostatics, hydraulics, optics and acoustics.
5. In Latin, an examination upon such elementary work as the student may offer, showing a familiarity usually attained by one year of study; for example, the reading of the first fifteen chapters of Cæsar's Commentaries, and the translation into Latin of easy English sentences involving the same vocabulary.

SEC. 2.—In place of this examination, or any part of it, colleges, members of this Association, are at liberty to recognize the official certificates of reputable literary and scientific colleges, academies, high schools and normal schools, and also the medical student's certificate issued by any State examining board covering the work of the foregoing entrance examination.

SEC. 3.—Colleges, members of this Association, may allow students who fail in one or more branches in this entrance examination the privilege of entering the first year course, but such students shall not be allowed to begin the second course until the entrance requirements are satisfied.

SEC. 4.—Colleges, members of this Association, are free to honor official credentials issued by medical colleges of equal requirements, except in the branches of study embraced in the last year of their own curriculum.

SEC. 5.—Candidates for the degree of Doctor of Medicine in the year 1899 and thereafter shall have attended at least four courses of medical instruction, each course of at least six months duration, no two courses of which shall have been in the same calendar year.

SEC. 6.—Colleges, members of this Association, are free to give to students who have met the entrance requirements of the Association additional credit for time on the four years' course as follows: 1. To students having the A.B., B.S., or equivalent degree from reputable literary colleges, one year of time. 2. To graduates and students of colleges, of homeopathic or eclectic medicine, as many years as they attended those colleges, provided they have met the previous requirements of the Association and that they pass an examination in materia medica and therapeutics. 3. To graduates of reputable colleges of dentistry, pharmacy and veterinary medicine, one year of time.

SEC. 7.—Colleges, members of this Association, may confer the degree of Doctor of Medicine during the year 1898 upon students who have attended three courses of six months' duration each. Each course shall have been in a separate calendar year.

Fifty-eight colleges have maintained membership by paying their dues for this current year.

1. University of California. 2. University of Louisville. 3. Rush Medical College. 4. Cincinnati College of Medicine and Surgery. 5. Medical Department University of Georgetown. 6. Medical College of Indiana. 7. Medical Department Columbian University. 8. Gross Medical College. 9. Syracuse University. 10. University of Denver. 11. Jefferson Medical College. 12. Creighton Medical College. 13. Kentucky School of Medicine. 14. Iowa College of Physicians and Surgeons; Drake University. 15. St. Louis College of Physicians and Surgeons. 16. College of Medicine, Los Angeles, Cal. 17. Ohio Medical University. 18. Michigan College of Medicine and Surgery. 19. Sioux City College of Medicine. 20. American Missionary Medical College.[1] 21. College of Physicians and Surgeons, Boston. 22. Hospital College of Medicine, Louisville. 23. Detroit College of Medicine. 24. Louisville Medical College. 25. Central College of Physicians and Surgeons, Indianapolis. 26. College of Physicians and Surgeons, Baltimore. 27. Western Pennsylvania Medical College. 28. Medico-Chirurgical College, Philadelphia. 29. Niagara University, Buffalo. 30. Wisconsin College of Physicians and Surgeons. 31. University of Maryland, Baltimore. 32. Baltimore Medical College. 33. University of Iowa. 34. Woman's Medical College, Philadelphia. 35. Arkansas Industrial University. 36. Howard University, Washington, D. C. 37. Starling Medical College, Columbus. 38. University of Minnesota. 39. College of Physicians and Surgeons, Cleveland. 40. University of Buffalo. 41. Toledo Medical College. 42. College of Physicians and Surgeons, University of Illinois. 43. University of Colorado. 44. National University, Washington, D. C. 45. Keokuk Medical College, Iowa. 46. College of Physicians and Surgeons, Hamlin University, Minnesota. 47. Western Reserve University. 48. University Medical College, Kansas City. 49. University of Michigan. 50. Tuft's College, Medical School, Boston.[1] 51. Johns Hopkins University. 52. Woman's Medical College, Northwestern University. 53. Fort Wayne College of Medicine. 54. University of Virginia. 55. University of Oregon. 56. Baltimore University. 57. Willamette University. 58. Barnes Medical College, St. Louis.

J. W. HOLLAND, M.D., Philadelphia, President; BAYARD HOLMES, M.D., 104 East Fortieth Street, Chicago, Secretary; Dudley S. Reynolds, M.D., Louisville, Chairman Judicial Council.

[See also page 643.]

BIRMINGHAM MEDICAL COLLEGE.

BIRMINGHAM, ALA.

This College requires for graduation, a three years' graded course of six months each.

The fee for the first year is $100; for the second year $100, and for the third year $125.

The students have the privilege of attending free the clinics of the Hillman Hospital, Hospital of the Tennessee Coal, Iron and Railroad Co. Several private infirmaries are also institutions to which the students have access. There is given in the College infirmary, a clinic every day (excepting Sunday) from 12 to 1 o'clock, in which special instruction is given, without extra cost, in gynecology and abdominal surgery, diseases of the ear, eye, throat and nose, skin, nervous system and children; also orthopedic and genito urinary surgery.

George A. Hogan, M.D., Secretary.

MEDICAL COLLEGE OF ALABAMA.

MEDICAL DEPARTMENT OF THE UNIVERSITY OF ALABAMA.

MOBILE, ALA.

The thirty-second session begins Oct. 11, 1897, and continues six calendar months. Every facility is offered for thorough medical instruction with a large and commodious college building; splendidly equipped laboratories. Ample clinical facilities. Spacious lecture rooms and magnificent museum. Delightful winter climate.

For further information or catalogue address George A. Ketchum, M.D., Dean, 7 N. Conception St.

---

[1] Application for membership.

MEDICAL DEPARTMENT, ARKANSAS INDUSTRIAL UNIVERSITY.

LITTLE ROCK, ARK.

The ninteenth annual course of lectures begins in this institution on Oct. 18, 1897.

Graded course. Four courses of lectures not less than six months each required. Clinical facilities and anatomic material ample. J. A. Dibrell, M.D., Dean.

COLLEGE OF PHYSICIANS AND SURGEONS OF SAN FRANCISCO.

SAN FRANCISCO, CAL.

This college held its first session during 1896-97, and has a full corps of professors, adjuncts, lecturers, demonstrators and assistants. It is located in the center of the most populous district of San Francisco, where clinical material is abundant. There are separate medical and dental courses, both graded, the former occupying four years, but the course is so arranged that a student matriculating therefor may take both courses at the same time and graduate with the two degrees of M.D., D.D.S. Daily clinics are held and the students have entrance to several hospitals. The fee for matriculation is $5; for each preliminary course, $25; for each regular course, $75; for the final examination, $25.

The preliminary course begins in October and ends at Christmas. The regular course begins in January and will continue six months. Advanced standing is given under definite regulations and examination when necessary.

For further information address Winslow Anderson, M.D., Dean, 603 Sutter St.

COOPER MEDICAL COLLEGE.

SAN FRANCISCO, CAL.

The college has handsome and commodious buildings, with fine laboratories and elaborate apparatus for illustrating lectures. An educational qualification or examination is required before admission. Four courses of six months each and one course of three months are necessary to complete the curriculum. Short term begins February 1; long, or regular term, June 1. Graduation exercises takes place in December. The objections to the summer course, which obtain on the Atlantic border, are unknown here. The long dry summer permits the carrying on of dissection and study to much greater advantage than in the winter, either here or in other climates. Excellent clinical facilities are offered. A fee of $130 is charged for each of these courses, $5 for matriculation, $10 for the demonstrator's ticket and $40 for graduation. Henry Gibbons, Jr., M.D., Dean; W. Fitch Cheney, M.D., Secretary.

UNIVERSITY OF CALIFORNIA, MEDICAL DEPARTMENT.

SAN FRANCISCO, CAL.

The course of instruction in the Medical Department of the University of California extends over four years. The course is graded, anatomy, physiology, histology, chemistry and materia medica being completed at the end of the second year. To be eligible for admission the applicant must present credentials equivalent to a diploma from a recognized high school or pass the examinations for admission to the academic branches of the university. Besides the regular clinical work at the City and County Hospitals the faculty conducts a free dispensary clinic in a thickly populated district where material is abundant. During the year ending April 30, 1897, 4,248 new cases were treated at the dispensary. The sessions of the college begin September 1 and continue eight calendar months. R. A. McLean, M.D., Dean.

GROSS MEDICAL COLLEGE.

DENVER, COLO.

The college is a member of the Association of American Medical Colleges and is specially stringent concerning the requirements for admission and graduation. The term begins Sept. 7, 1897, and continues seven months. The course of study extends over four years. The fees are: Matriculation fee, $5; general lecture fee, $75, except for the senior year when the fee is $30. There is no examination fee. Sons and daughters of ministers and physicians are admitted on the payment of one-half of the general lecture fee. There are laboratory fees for material and to cover breakage. Especial advantages are given in laboratory and clinic work. Owing to the recent abandonment of the State School in Denver the larger portion of the active teachers of this faculty have associated themselves with the Gross Medical College. Robert Levy, M.D., Secretary, California Building.

UNIVERSITY OF COLORADO, MEDICAL DEPARTMENT.

BOULDER, COLO.

This college completed its fourteenth annual session June 4, 1897. For the session of 1897 and 1898 the college will conduct but the first two years of a four years' graded course. For the work of the first two years the university is exceptionally well equipped in faculty, room and laboratories. The course is arranged to harmonize with the best scientific work of the day. The two years are largely devoted to laboratory work in chemistry, physiology, anatomy, histology, materia medica, pharmacology, pathology and bacteriology. The next session begins Sept. 7, 1897, and will continue nine months. The tuition fee is $35 per year. This is payable on entering the school. There are no other fees. Further information will be given by addressing L. M. Griffin, M.D., Dean.

UNIVERSITY OF DENVER, MEDICAL DEPARTMENT.

DENVER, COLO.

The Medical Department of the University of Denver will open Oct. 5, 1897, and continue seven months. The course of instruction embraces four separate terms of seven months each. Fees: Matriculation, paid but once, $5; registration, paid annually after first registration, $1; tuition, annually payable in advance, $75; chemical laboratory, $10; dissecting material at cost, not to exceed $5 per part; graduation fee, $25.

Denver, with a population of 150,000, offers excellent clinical advantages for instruction at both dispensary and hospital. Students in impaired health can and do attend the Medical Department of the University of Denver and regain their health in this great health resort. For catalogue address the Secretary, E. R. Axtell, M.D., Barth Block.

THE COLUMBIAN UNIVERSITY, MEDICAL DEPARTMENT.

WASHINGTON, D. C.

The seventy-sixth session of the Medical Department of the Columbian University will begin on Sept. 29, 1897. During the coming year the clinical facilities of the college will be increased by opening a hospital, which is very conveniently located within a few doors of the lecture building. This hospital, when started, will be under the exclusive control of the medical faculty. As heretofore, all possible clinical facilities will be given to the students, and great stress will be laid on the practical work in connection with all of the different branches. E. A. DeSchweinitz, M.D., Dean.

HOWARD UNIVERSITY, MEDICAL DEPARTMENT.

WASHINGTON, D. C.

This college is open to all students who are qualified.

The thirtieth annual session will begin Oct. 1, 1897, and continue seven months.

Tuition is $60, with a small fee for laboratory expenses.

Instruction is given by didactic and clinical lectures, recitations and practical exercises.

Howard University offers special facilities to students. Situated at Washington, D. C., with many libraries and museums open at all times to the student; with the Army Medical Museum, which is the finest in the world, easy of access; with the many hospitals of the city offering ample clinical facilities, and especially the Freedmen's Hospital, located on the grounds of the University.

Howard University can point with pride to the fact that she was among the first to adopt a four years graded course.

Prof. T. B. Hood, Dean; Prof. F. J. Shadd, Secretary and Treasurer.

MEDICAL DEPARTMENT, GEORGETOWN UNIVERSITY.

WASHINGTON, D. C.

This school offers unusual facilities for medical education. By an act of Congress, the various libraries and museums are open to students, and the Faculty frequently make use of these collections for demonstrations. The forty eighth session opens October 4 and will continue seven and one-half months. Instruction is given by lectures, recitations, clinics and laboratory demonstrations. The laboratories are well equipped with the most modern apparatus.

Clinical facilities are ample. The Georgetown University Hospital, now under construction, will soon add greatly to the opportunities for bedside instruction. The lectures are now given during the day, as students are required to give their entire time to their studies. Good [illegible] ined at from $20 to $25 per month. Fees: [illegible] de but once, $5; tuition including labo.

G. L. Magruder, M.D., Dean.

ATLANTA MEDICAL COLLEGE.

ATLANTA, GA.

This is one of the oldest schools in the South. To keep abreast with the demand for higher medical education, this school has within the last five years spent upward of fifteen thousand dollars in equipping chemic, pathologic and bacteriologic laboratories, courses in which are compulsory and a requisite to graduation.

Atlanta, with over a hundred thousand inhabitants, affords an abundance of clinical material. The wards of the City Hospital are open to students and the members of the Faculty are upon the visiting staff. The course consists of three full terms of six months each, taken in separate years. The fees are $100 for each course. The Faculty employs an able corps of instructors, demonstrators and quiz-masters to whom the student pays no extra fee.

MEDICAL DEPARTMENT, UNIVERSITY OF GEORGIA.

AUGUSTA, GA.

The sixty-sixth annual session commences Oct. 1, 1897, and terminates April 1, 1898.

During the three years' graded course, six months in each year, students are thoroughly instructed in all departments of medical science. Facilities for instruction at bedside in practice of medicine, surgery, ophthalmology, gynecology and obstetrics, are unsurpassed by any medical college in America. Three large hospitals are under the exclusive control of faculty of this college, and fully utilized for practical instruction of students. Each member of the graduating class is accorded the benefit of two weeks' residence in the hospitals.

Fees: Matriculation, $5; general course of instruction, $75; practical anatomy, $10; laboratory fees (histology and pathology), $10; diploma, $30. Announcement giving full particulars of the course, furnished on application. Address Eugene Foster, M.D., Dean.

SOUTHERN MEDICAL COLLEGE.

ATLANTA, GA.

The nineteenth annual session will open October 1. The course is six months and three graded courses, in separate years, are required of every applicant for graduation. Each course includes systematic, didactic and numerous clinical lectures, besides the usual laboratory and dissecting room instruction. The faculty consists of fifteen regular professors and thirteen assistants. The clinical advantages are unsurpassed. In addition to an inexhaustible out door clinic, the Grady Hospital, with its 150 beds, is available to advanced students, who have the privilege of attending without charge medical, surgical and gynecologic clinics in the hospital amphitheater, and under the supervision of the visiting physicians and surgeons, a large proportion of whom are members of the faculty. They have almost daily access to the hospital wards.

The fees, including demonstrator and laboratory fees, are $100 per session.

James B. Baird, M.D., Dean.

CHICAGO CLINICAL SCHOOL.

CHICAGO, ILL.

The Chicago Clinical School, formerly called the West Chicago Post-Graduate School and Polyclinic, located at 819 West Harrison Street, has just issued "Bulletin No. 6," giving general information regarding the special courses, for the coming winter. The directors of the School have had in view the accommodation of post-graduate students and have made wise and extensive improvements in their school. The operating rooms are fitted with the most modern apparatus for surgical, gynecologic and ophthalmologic work. The hospital building in which the school is located has a capacity of 125 beds, and no expense has been spared to make the hospital perfect in modern conveniences, both for the requirements of the patient and of the physician and surgeon.

CHICAGO COLLEGE OF DENTAL SURGERY.

DENTAL DEPARTMENT OF LAKE FOREST UNIVERSITY.

CHICAGO, ILL.

The Annual Winter Course of Instruction will begin about October 1, and end about April 1.

Three full winter courses of lectures are required before graduation. Graduates of pharmaceutic and undergraduates of medical colleges in good standing, and graduates of reputable veterinary colleges are admitted to the second year course.

Freshman Year 1897-98: Matriculation fee, $5; general ticket, $100; histologic laboratory ticket, $5; dissection fee (one part) $10. Junior Year, 1897-98: Matriculation fee, $5; general ticket, $100. Senior Year, 1897-98: Matriculation fee, $5: general ticket, $100.

A fee of $5 must be deposited to cover chemicals and breakage in the chemical laboratory.

The building occupied by the Chicago College of Dental Surgery is, in all its appointments, one of the most perfect and complete of its kind. Letters of inquiry should be addressed to Dr. Truman W. Brophy, Dean, 126 State Street.

CHICAGO EYE, EAR, NOSE AND THROAT COLLEGE.

CHICAGO, ILL.

The Chicago Eye, Ear, Nose and Throat College has been founded with the idea of giving post-graduate instruction and of thoroughly fitting its students for practicing the above named branches of special medicine. The College is located in the Trude Building, 67 Wabash Avenue. The central location and easy accessibility from all parts of the city insures a large amount of clinical material. The college equipment is the best money can buy, and the facilities for teaching the above named branches are unsurpassed. The faculty is made up of men who have had wide experience in this line of work and are alive to the needs of men who wish to practice it. For further information and catalogue write to J. R. Hoffman, M.D., Secretary.

CHICAGO POLICLINIC AND HOSPITAL.

CHICAGO, ILL.

The Chicago Policlinic has fallen into line with the other institutions in their endeavor to meet the good times that are coming. They have arranged the work of the institution to meet the requirements of a great variety of medical and surgical interests in their various departments. The Policlinic is in a position to offer what is a great essential in a clinical school—exceptional opportunities for individual handling of cases under expert instruction and unusually extensive facilities for observing after-treatment and the most approved forms of dressing in their own hospital. They are enabled to do this by carrying on a very large amount of hospital and dispensary work, treating, on an average 150 cases a day. Students may enter on a course at any time since the work is so arranged. F. Henrotin, M.D., Secretary, 174 E. Chicago Avenue.

CHICAGO SCHOOL OF GYNECOLOGY AND ABDOMINAL SURGERY.

CHICAGO, ILL.

This is a post-graduate school for special and practical instruction in gynecology, diseases of the abdomen and abdominal surgery. All teaching is clinical.

Monthly courses are given the year round. Rectal, genito-urinary and gastro intestinal diseases will be taught. Practitioners may enter at any time.

"Touch" courses and clinics for physical diagnosis will be conducted from 9 A.M. to 2 P.M. The afternoons will be devoted to operative clinics at the varying hospitals with which the faculty are associated.

Arrangements may be made at the School for operative and practical work on the cadaver.

The fees are from $35 to $75, according to courses chosen.

The small classes allow individual advantages in gynecologic examinations and observations at operations. Byron Robinson, M.D., 100 State Street, Secretary.

THE COLLEGE OF PHYSICIANS AND SURGEONS.

SCHOOL OF MEDICINE, UNIVERSITY OF ILLINOIS.

CHICAGO, ILL.

The fall term of the College of Physicians and Surgeons of Chicago (Medical Department of the University of Illinois) begins September 21. The introductory address will be delivered by Prof. Adolph Gehrmann. The term ends April 19. The fees are $110. Women are admitted on an equality with men.

There are six large fully equipped laboratories. The West Side Hospital adjoining and connected with the college building affords abundant clinical facilities, with daily clinics in the college amphitheater and outdoor obstetric clinics.

Six annual scholarships of the value $100 each are awarded to students in the college. Four years graded course.

W. E. Quine, M.D., Dean, D. A. K. Steele, M.D., Actuary; Wm. Allen Pusey, M.D., Secretary, 103 State Street.

HARVEY MEDICAL COLLEGE.

CHICAGO, ILL.

The course of study is graded to extend over a period of four years; is given by fifty professors; illustrated by lectures, laboratory work and quizzes, between the hours of seven and ten o'clock every week-day evening. Special attention is given to anatomy. Individual cadavers furnished [illegible] Every student is obliged to perform operations [illegible]

JENNER MEDICAL COLLEGE.

CHICAGO, ILL.

Jenner Medical College is a co-educational school where an education in medical science may be gained by evening study. It is recognized by the State Board of Health and is now in its fifth year. Its course of four terms, of more than nine months each—September 7 to June 18—makes the total number of hours put in by its students in excess of the requirements of the Association of American Medical Colleges. Lectures commence at 7 and continue to 10 o'clock, six evenings each week. The facilities for laboratory and clinical work at Jenner are up to date. In connection with the college is conducted the Jenner Hospital, where bedside instruction is provided for the students, 385 Washington Boulevard.

The *fees are*: Matriculation (paid but once) $5; laboratories, $5; general fee, $75 each year. E. Perry Rice, M.D., Secretary.

NORTHWESTERN UNIVERSITY MEDICAL SCHOOL. (CHICAGO MEDICAL COLLEGE.)

CHICAGO, ILL.

This school was the first in this country to enforce a standard of preliminary education; to adopt longer annual courses of instruction; and to grade the curriculum.

Four years of study are required for graduation. Applicants for admission must present diploma from colleges of arts, science, or acredited high schools, or pass the examination required for entrance to the College of Liberal Arts of Northwestern University.

A feature unique to this school is the grading of clinical instruction and the maintenance of small clinics, so that students can obtain individual instruction.

Instruction is given by lectures, recitations, conferences, laboratory and clinical methods. Elective courses are afforded.

The laboratory building contains finely planned and equipped laboratories.

The faculty consists of thirty-nine professors and forty-three instructors and demonstrators.

College opens Oct. 5, 1897. Commencement is June 16, 1898. The *fees are*: Matriculation $5; annual $125. N. S. Davis, M.D., Dean.

NORTHWESTERN UNIVERSITY WOMAN'S MEDICAL SCHOOL.

CHICAGO, ILL.

Examination for admission begins Sept. 27, 1897; first semester Oct. 7, 1897.

The course is four years, graded.

A matriculation fee of $5 is required; an annual fee of $75, and a final examination fee of $30.

An addition to the college buildings in course of construction will double the laboratory and clinical facilities.

College clinics will be given in dermatology by Professor Zeisler; in pediatrics by Professor Abt; in gynecology by Professor Mergler; in obstetrics by Professor Root; in orthopedic surgery by Professor Ridlon; in ophthalmology and otology by Professor Fiske; in surgery by Professors Graham and Van Hook; in laryngology by Professor Rhodes; in general medicine by Professors Danforth and Edwards; and in neurology by Professor Brower. Hospital clinics and bedside instruction will be given at Cook County Hospital and also clinics at the Woman's Hospital, the Wesley Hospital, the Detention Hospital, and at the Mary Thompson Hospital for Women and Children.

POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL OF CHICAGO.

CHICAGO, ILL.

This college is now entering upon its ninth year. The facilities for post-graduate teaching are thorough and complete in all departments, including hospital, clinical and laboratory advantages, which are not excelled anywhere. Teaching is exclusively clinical, with abundant material and small classes and large working faculty. It is located in the medical center of the city. With a continuous course throughout the year, practitioners can matriculate at any time with equal advantage. There is a large hospital in the main building and extensive outside hospital connections. The laboratories are unsurpassed in equipment. Systematic courses are given the practitioner under the direct supervision of Prof. Theo. A. Edwin Klebs (late of the University of Zurich and widely known through the researches which resulted in the discovery of the diphtheria bacillus).

An illustrated bulletin will be furnished upon application to Franklin H. Martin, M.D., Secretary, 2400 Dearborn street.

RUSH MEDICAL COLLEGE.

MEDICAL DEPARTMENT LAKE FOREST UNIVERSITY.

CHICAGO, ILL.

The curriculum of this school of medicine requires a proper preliminary education and four years of study in college, devoted to laboratory, didactic and clinical instruction, to recitations and to manual training in the use of instruments and appliances.

Instruction is given in two capacious, well lighted edifices. The new building contains five large laboratories, in which are conducted the practical laboratory courses in anatomy, physiology and histology, chemistry, materia medica, pathology and bacteriology.

The old building is devoted to instruction by clinics, didactic lectures, and by numerous important practical courses in manual training in manipulations and in the use of the instruments employed in medicine, surgery, obstetrics, and the specialties.

For further information and for announcements apply to the College Clerk, or to the Secretary, J. H. Etheridge, M.D., 31 Washington St.

THE CENTRAL COLLEGE OF PHYSICIANS AND SURGEONS.

INDIANAPOLIS, IND.

The nineteenth annual session of The Central College of Physicians and Surgeons will open Wednesday, Sept. 15, 1897, and continue *for six full months, on the four years system.* The College Free Dispensary, located in the college building, together with the City Hospital, St. Vincent's Infirmary and the City Dispensary, afford an abundance of clinical material. Classes are so divided as to enable the instructors to give personal instruction to each student. Each senior attends at least four cases of obstetrics under the direction of the professor of that department. The laboratories are generously equipped. Professors' and laboratory fees complete, $60. Joseph Eastman, M.D., LL.D., President; S. E. Earp, B.Sc., M.D., Secretary.

FORT WAYNE COLLEGE OF MEDICINE.

FORT WAYNE, IND.

This college has issued its "Nineteenth Annual Announcement," and has a four years' graded course of six months each year. General lecture fee, including laboratory, dissecting and hospital tickets, each year $70.

This college was the second in this country to require a four years' graded course before conferring the degree of Doctor of Medicine.

Clinics are held in the St. Joseph and Hope Hospitals, also once a week in the State Institute for Feeble Minded Youth, and daily in the College Dispensary. Session of 1897 98 opens Sept. 14, 1897.

The faculty consists of twenty-two professors, with a number of lecturers, demonstrators and clinical assistants.

The clinical advantages are good, with sufficient material for demonstration. The college has always maintained a high standard of requirements.

Address all communications to C. B. Stemen, M.D., Dean 25 Broadway; or W. W. Barnett, M.D., Secretary, 25 West Wayne St.

MEDICAL COLLEGE OF INDIANA.

DEPARTMENT OF MEDICINE OF THE UNIVERSITY OF INDIANAPOLIS.

INDIANAPOLIS, IND.

This college was organized in 1869 and will open its twenty-eighth session on Sept. 28, 1897. It offers a *four years'* graded course, the classes being rigidly separated; women admitted on the same terms as men; clinical facilities first-class; free dispensary in the college building, maintained and operated by the faculty; new building erected *especially for* the institution and adapted to the requirements of advanced medical education; *new clinic rooms, modern in every respect,* at both hospitals.

The faculty numbers twenty, with sixteen lecturers, assistants and demonstrators. For all information address Joseph W. Marsee, M.D., Dean, 206½ E. New York St.

IOWA COLLEGE OF PHYSICIANS AND SURGEONS.

MEDICAL DEPARTMENT OF DRAKE UNIVERSITY.

DES MOINES, IOWA.

This college has a four years' graded course, principally laboratory work; the last two years clinical work.

The school is located in the largest city in Iowa and affords corresponding clinical advantages.

The regular fall and winter session begins Sept. 21, 1897, and continues twenty-six weeks. For announcement or information, address O. D. Benson, M.D., Secretary, Sixth and Locust Sts.

KEOKUK MEDICAL COLLEGE.

KEOKUK, IOWA.

Keokuk Medical College was founded in 1890 by a corps of experienced medical teachers; graduated its first class in 1891 and has graduated large classes each subsequent year. It has now an active alumni of over three hundred.

The Faculty is composed of twenty professors and assistants. The requirements for admission and graduation are of high grade. The course is graded and extends over a period of four separate calendar years. The college building, in all its equipment, is modern. St. Joseph's Hospital is controlled by the College, for all clinical purposes; abundant clinics in all departments. Session opens September 14. Oliver D. Walker, M.D., Secretary.

MEDICAL DEPARTMENT OF THE STATE UNIVERSITY OF IOWA.

IOWA CITY, IOWA.

The Medical Department of the State University of Iowa, at Iowa City, opens its twenty-eighth session on September 15, and continues it until March 30. The new University Hospital, for which an appropriation was made by the last General Assembly, and which is managed by this Department, is rapidly nearing completion. It embodies the latest and best ideas in hospital architecture and in structure and equipment will be without a superior in the West. Clinic patients are received from all parts of Iowa as well as from many of the Northwestern States. The didactic and laboratory instruction is not made subordinate to the clinical. The large and well-furnished laboratories afford special advantages for practical work. The annual fee, which includes all university charges, is $65.

COLLEGE OF PHYSICIANS AND SURGEONS (MEDICAL DEPARTMENT OF KANSAS CITY UNIVERSITY).

KANSAS CITY, KANS.

The fourth annual session of the College of Physicians and Surgeons will open Sept. 15, 1897, and continue for six months. The school is well equipped for teaching modern medicine and surgery with first class hospital connections where all surgical operations can be seen; also an abundance of medical cases of all the various diseases can be seen daily. The faculty is composed of practical men, familiar with the needs of medical students. For catalogue or other information, address J. W. May, M.D., Dean, or E. M. Hetherington, M.D., Secretary, Kansas City, Mo.

KANSAS MEDICAL COLLEGE.

TOPEKA, KANS.

Session began Sept. 14, 1897, and continues twenty-six weeks. It is a three years' school.

The trustees and faculty own the college building and ten beautiful lots adjoining. Aside from the college clinic and free dispensary, students are required to attend the clinics at Christ's Hospital, State Insane Asylum and Salvation Army Hospital. There are two other hospitals in the city to which students have access, and two private hospitals, making the clinical facilities equal to any college in the country. Kansas has now an excellent anatomic law. Tuition in full for the first year is $65; second year, $65; third year, $35. Board and room rent from $3.50 to $5 per week. J. E. Minney, A.M., M.D., Dean; R. S. Magee, M.D., Secretary.

HOSPITAL COLLEGE OF MEDICINE.

MEDICAL DEPARTMENT OF CENTRAL UNIVERSITY.

LOUISVILLE, KY.

The twenty-fourth annual session of the Hospital College of Medicine will begin Jan. 3, 1897, and continue six months. The curriculum is graded and attendance upon four full courses is required.

College graduates in arts or science who have pursued certain biologic studies; graduates in dentistry, pharmacy and veterinary surgery are admitted to advanced standing. Practical instruction, including laboratory work in chemistry, histology, osteology, pathology, bacteriology and anatomy, with bedside instruction in medicine, surgery, gynecology, obstetrics and diseases of the eye, ear, nose and throat, is a part of the regular course. Hospital and clinic advantages are unsurpassed. For catalogue and further information address P. Richard Taylor, M.D., Dean, 229 West Chestnut Street.

KENTUCKY SCHOOL OF MEDICINE.

LOUISVILLE, KY.

This College is midway between the North and the South and holds its sessions from January to June inclusive. It began in 1817 as the Medical Department of Transylvania University, and took its present name in 1850. With a progressive and experienced faculty of thirty teachers, ample and thoroughly equipped laboratories and a large modern hospital of its own, recently erected adjoining the college, this school is offering facilities for practical and thorough instruction unsurpassed in this country. Advanced students, in sections of about six, are drilled every day in actual work in the indoor and outdoor departments of the College Hospital. The requirements for entrance, graduation, etc., conform to those of the Association of American Medical Colleges. The fees are: Matriculation, $5; tuition, $75; laboratories, each $10; examination each year, $10. For catalogue address Samuel E. Woody, M.D., Dean.

MEDICAL DEPARTMENT, TULANE UNIVERSITY OF LOUISIANA.

NEW ORLEANS, LA.

This institution, founded in 1834 as the Medical College of Louisiana, became in 1884 the Medical Department of the Tulane University of Louisiana. It is the oldest college in the Southwest. The next annual course of instruction will begin *Oct. 14, 1897. It possesses well-equipped laboratories for* chemistry, pharmacy, practical anatomy, operative surgery, microscopic anatomy, pathology and bacteriology, and working rooms for practical physiology and gross pathologic anatomy. These admirable laboratories, now added to the unrivaled practical advantages for clinical, anatomic and pathologic studies given by the Charity Hospital, enables the Medical Department to provide its students with unsurpassed advantages for their medical education. The Faculty solicits the special attention not only of students, but also of graduates of other colleges, to the unequaled clinical and anatomic advantages. The fees amount to a total of $465 for a three years' course. For other information address S. E. Chaille, M.D., Dean.

NEW ORLEANS UNIVERSITY MEDICAL COLLEGE.

NEW ORLEANS, LA.

New Orleans University Medical College is located near the center of the city. The course of instruction covers four years of six months each. Tuition is $30 per session, which entitles to attendance on all lectures, daily clinics and hospital privileges—the hospital wards being in the second story of the main building. It is the only school in the far South open to all irrespective of race or sex.

The mild winter season with its long period of daily sunshine makes New Orleans a delightful climate for students subject to catarrhal or pulmonary troubles. Session opened September 14.

BOWDOIN COLLEGE, MEDICAL DEPARTMENT.

BRUNSWICK, MAINE.

Its seventy-eighth annual course will begin Thursday, Jan. 6, 1898, and continue until the following June 26.

Its course of lectures includes anatomy, physiology, chemistry, pathology and practice, surgery, materia medica, obstetrics, diseases of women, diseases of children, medical jurisprudence, mental diseases; surgical and medical clinic on Thursdays and Saturdays of each week, also clinical lectures and instruction in diseases of eye and ear; good laboratory facilities in chemistry, histology and bacteriology; a well equipped anatomic cabinet.

Matriculation fee, $5; lecture fee, $78 each for first and second courses, $50 for third course; diploma fee, $25. Dissection material furnished at cost. Price of board, including room and incidentals, from $4 to $5 weekly. For full information send for catalogue to Alfred Mitchell, M.D., Secretary.

BALTIMORE MEDICAL COLLEGE.

BALTIMORE, MD.

The preliminary fall course begins September 1; regular winter course October 1.

Excellent teaching facilities; magnificent new college buildings; superb lecture halls; large and completely equipped laboratories; capacious hospitals and dispensary; lying-in department for teaching clinical obstetrics; large clinics.

Send for catalogue, and address David Streett, M.D., Dean, N. E. cor. Madison Street and Linden Avenue.

BALTIMORE UNIVERSITY, SCHOOL OF MEDICINE.

BALTIMORE, MD.

The next session will open October 1, and continue six months. The second session will open about April 15 and continue until August 1. The fees for the first session will be $70 and the fees for the second $45. We have ample hospital facilities and large clinics in both the indoor and out door department dispensary. The instruction consists in didactic lectures, clinical teaching and bedside instruction, bringing the student in close contact with all the different phases of disease, the recognition and treatment, and unexcelled opportunities for witnessing surgical operations and manipulation upon patients. The Baltimore University Hospital is owned by the Faculty of this School, and in close proximity. Ample opportunity for witnessing obstetric cases is constantly afforded, and it is run as a temperance institution. Our college is a member of the Association of American Medical Colleges. H. H. Biedler, M.D., Dean.

COLLEGE OF PHYSICIANS AND SURGEONS OF BALTIMORE.

BALTIMORE, MD.

The twenty-fifth annual session opens Oct. 1, 1897. The length of the term is six months. Having adopted the four years' graded curriculum in 1895, in advancce of the mandate of the national Association of Medical Colleges, the school is now well organized on this plan. The cost of attendance upon the lecture course is $100. The diploma fee is $30.

The instruction consists of clinical and didactic lectures, recitations, ward classes in medicine, histology, pathology, bacteriology and physiology, and anatomic demonstrations. The college and hospital facilities comprise the college building proper; the Baltimore City Hospital; the Hospital for the Colored Race; the Maternité Hospital; the Out door Department of Maternité Hospital; the City Hospital Dispensary and Bay View Asylum.

The Faculty have added a Pasteur department, for the treatment of rabies.

THE JOHNS HOPKINS MEDICAL SCHOOL.

BALTIMORE, MD.

The required period of study is four years. Only those are admitted as candidates for the degree who possess a degree in arts or science from an approved college and have had at least a year's collegiate training, with much laboratory work, and have acquaintance with Latin and a reading knowledge of French and German. In the methods of instruction especial emphasis is laid upon practical work in the laboratories and in the dispensary and wards of the hospital. Abundant clinical material is afforded by the Johns Hopkins Hospital and Dispensary. Especially advantageous for thorough clinical training are the arrangements by which the students engage in practical work in the Dispensary, and throughout the fourth year serve as clinical clerks and surgical dressers in the wards of the Hospital. The charge for tuition is $200 per annum.

Inquiries may be addressed to the Registrar of the Johns Hopkins Medical School.

UNIVERSITY OF MARYLAND, FACULTY OF PHYSIC.

BALTIMORE, MD.

The ninety-first annual session of the University of Maryland, School of Medicine, will begin October 1, and end April 20, 1898. It offers a four years' graded course, methods of instruction eminently practical and splendid laboratory equipment. The magnificent new University Hospital, which is under the exclusive control of the Faculty, offers unsurpassed clinical advantages. The advanced classes are divided into small sections, so that each student receives individual instruction in all the practical branches of medicine. The Lying-in Hospital, which has probably the largest clinic in the South, offers unusual facilities for the teaching of obstetrics. For catalogue and other information address C. W. Mitchell, M.D., Dean, 1021 Cathedral Street.

WOMAN'S MEDICAL COLLEGE OF BALTIMORE.

BALTIMORE, MD.

The Woman's Medical College of Baltimore was founded in 1882. Session begins October 1 and ends June 1. Four years' attendance is required for graduation. There are thirty-four instructors and assistants. The clinical advantages include the Hospital of the Good Samaritan, the Maternité, the Presbyterian Eye, Ear and Throat Hospital, Bay View Hospital and a large dispensary service. Instruction is given in psychiatry, embryology, laboratory work in histology, embryology, pathology, bacteriology, chemistry and pharmacy. Fees for a full course, $100, with reduction of 25 per cent. to missionaries. Five dollars is required for breakage and $30 for final examinations. The rules of the Association of American Medical Colleges are strictly enforced. For terms and catalogue, address Eugene F. Cordell, M.D., Secretary, 1100 McCulloh Street.

COLLEGE OF PHYSICIANS AND SURGEONS.

BOSTON, MASS.

The College is now in its eighteenth year. It was the first regular college in New England to admit both men and women to equal privileges. A four years' graded course is required, under the rules and requirements of the Association of American Medical Colleges, including didactic lectures, recitations, conferences, clinical teachings, and practical work in laboratories and dissecting room.

The regular session begins in September, and ends in June.

The lecture fee is $100 per year, except the first year, which is $75, (complete in advance, $300).

The College is located near the Boston City Hospital, and possesses other good clinical facilities, in which it gives each student experience and special training in general practice. The faculty comprises thirty-two professors, aided by special instructors and assistants. Augustus P. Clarke, A.M.,M.D., Dean; George F. Shurtleff, M.D., Registrar.

TUFT'S COLLEGE MEDICAL SCHOOL.

BOSTON, MASS.

It is the only regular co-educational medical college in New England where diplomas are recognized by the State Medical Society.

It has four years' graded course of eight months each. Entrance examinations (with a few exceptions) are required.

It has a new building, just finished, and thoroughly equipped laboratories, lecture rooms, amphitheater and dissecting rooms, separate study rooms for both sexes, dispensary in the building, and is near City and St. Elizabeth Hospitals for clinic facilities.

Next term commences Wednesday, Sept. 29, 1897. For further particulars, address C. P. Thayer, M.D., Secretary, 74 Boylston Street.

DETROIT COLLEGE OF MEDICINE.

DEPARTMENT OF MEDICINE.

DETROIT, MICH.

The Medical Department of this institution requires for admission a diploma from a reputable high school, or its equivalent. The course of study covers a period of four years of seven full months each. The first two years are devoted to the preliminary and fundamental branches, the last two to the general and technical study of the practice of medicine and surgery. The recitation system of teaching is largely employed. Laboratory instruction including also pathology, bacteriology, physiology and operative surgery, is made a special feature of the course. Practical obstetric work is required of senior students. Harper and St. Mary's Hospitals, attendance at which is compulsory, furnish an abundance of material of all kinds for clinical instruction in all branches. The total fees average about $100 per year. The next session opens Sept. 29, 1897. H. O. Walker, M.D., Secretary.

MICHIGAN COLLEGE OF MEDICINE AND SURGERY, DETROIT.

DETROIT, MICH.

The regular session opens Sept. 21, 1897, and continues six months. The period of study has been increased to a carefully graded course of four years.

The fees are within reach of all, averaging $75 per year. Students have access, free of charge, to the Detroit Emergency Hospital; Free Dispensary; Detroit Eye and Ear Infirmary; clinic for obstetrics, which provides senior students two or more clinical cases; clinic for venereal diseases; gynecology, skin, nose and throat, nervous system, children, thorax, surgery and clincal medicine.

An ambulance service is mantained exclusively in connection with the hospital, thus furnishing an opportunity both to witness the primary treatment of injuries and to perfect themselves in the details of dressing, nursing and [illegible] treatment. All accident and ambulance [illegible] are d[illegible] [illegible]efore the class.

On an average, 15,000 patients are treated annually in the Free Dispensary.

UNIVERSITY OF MICHIGAN.

DEPARTMENT OF MEDICINE AND SURGERY.

ANN ARBOR, MICH.

The course of medical instruction in this institution has, since 1890, consisted of four years of nine months each. The course is graded; the first two years being devoted to the fundamental branches of chemistry, physics, anatomy, physiology and hygiene by means of didactic lectures, quizzes and laboratory work; the remaining two years to special branches and clinical instruction.

One of the chief features of the instruction received here is the thorough practical knowledge which the student obtains in the various required laboratory courses.

The State hospitals, which were established here mainly to afford facilities for clinical instruction, furnish abundant material for acquiring practical experience in the observation and treatment of medical and surgical cases, and junior and senior students have unusual freedom of access to the wards. V. C. Vaughan, M.D., Dean.

HAMLINE UNIVERSITY,

COLLEGE OF PHYSICIANS AND SURGEONS.

MINNEAPOLIS, MINN.

This is the oldest institution of medical learning in Minnesota. The course is four years; the sessions of eight and a half months each. Matriculation fee is $5. Annual tuition for first three years, $65; for the fourth year $35; graduate course $50. No extra charges for laboratories or special courses. The faculty is made up of the ablest men selected from the profession of both Minneapolis and St. Paul. The college building is situated in the immediate neighborhood of the three chief hospitals of Minneapolis, and the hospitals of both cities are available for clinical instruction, giving ample material in all lines. The course is very thorough and rigid; the standard high; the moral tone especially good, and an unusual spirit of fellowship between the faculty and students exists. All laboratories have been refitted with the best apparatus necessitated by rapid growth, the enrollment having increased 70 per cent the past year. Leo M. Crafts, M.D., Dean.

UNIVERSITY OF MINNESOTA; COLLEGE OF MEDICINE AND SURGERY.

MINNEAPOLIS, MINN.

The Medical Department opens September 21. The course covers a period of four years of study, each year representing eight months in actual residence.

The studies are graded throughout the four years, with careful reference to the relations which the subjects naturally bear to each other. The work of the first two years deals with the laboratory branches; that of the third and fourth years include the principles and practice of medicine and surgery with their specialties and the application of scientific or laboratory methods to clinical experience. The hospitals of Minneapolis and St. Paul are open to the students *without fee*, and their clinical facilities are unexcelled. More than twenty-five hospital positions are open to graduates of this college through competitive examination. Level fees: First and second years, $100 each; third and fourth years, $75 each; graduation fee, $10.

For further information address Parks Ritchie, M.D., Dean.

BARNES MEDICAL COLLEGE.

ST. LOUIS, MO.

The Barnes Medical College of St. Louis presents strong claims for the confidence and patronage of the profession. Its new building is one of the most commodious and expensive structures devoted to medical teaching. Its laboratories of histology, physiology, chemistry, pathology, bacteriology and anatomy are among the largest and best equipped of the kind in the world. Its faculty is composed of carefully selected instructors, men of ability and of unblemished reputation, who are widely and favorably known.

Matriculates for the last session numbered 511. A four years' graded course of instruction is required. The tuition is exceedingly moderate, and special terms are given to sons of physicians and ministers. The college is centrally located and clinical advantages are excellent.

BEAUMONT HOSPITAL MEDICAL COLLEGE.

ST. LOUIS, MO.

The regular session begins September 21 and continues for six months. The course extends over three years and is graded. Laboratory exercises are obligatory in chemistry, physiology, uranalysis, histology, pathologic anatomy and bacteriology.

Clinics are regularly held at the City Hospital, the Alexian Brothers' Hospital, St. Mary's Infirmary and the Missouri Pacific Hospital. Other public institutions with which teachers in this school are connected also offer clinical advantages. Prominence is given to laboratory work and to clinical teaching.

Fees (payable in advance): Matriculation fee (paid but once), $5; fee for the junior year, $50; fee for the intermediate year, $70; fee for the senior year, $80; laboratory fee (yearly), $10. No additional charge will be made for hospital tickets, anatomic material or diploma. F. J. Lutz, M.D., Dean.

ENSWORTH MEDICAL COLLEGE AND HOSPITAL.

ST. JOSEPH, MO.

The Ensworth Medical College and Hospital is a partially endowed institution. The college department is well fitted for medical instruction; is up with the times as respects its curriculum, and possesses suitable rooms for lectures and laboratory work. Three terms of six months each constitutes its course of instruction, which is given by lectures and recitations. It seeks and desires students well equipped for the study of medicine by a liberal education. On Sept. 13, 1897, it entered on its twenty-first session. The hospital can accommodate 250 patients. It is well supplied with all necessary means. It is under the charge and special direction of a committee of the faculty. Tuition fees, $50; laboratory fee, $5; examination for degree, $25. Thomas H. Doyle, M.D., President; Hiram Christopher, A.M., M.D., Dean.

KANSAS CITY MEDICAL COLLEGE.

KANSAS CITY, MO.

The Kansas City Medical College, established in 1869, enters upon its twenty ninth annual session with the coming year. A three-years' graded course is established, each school year beginning September 14 and continuing twenty six weeks. The college building is well located, conveniently arranged and contains new and well equipped laboratories. Both lecture and recitation systems of instruction are employvd. The instruction is eminently practical, bedsides teaching being the feature. The dispensary service is large and the material fully utilized. The hospital and clinical facilities are excellent; a part of the courses completed each year. The fees are moderate, half the lecture fee charged to sons of physicians.

For information and announcement address the Dean, J. D. Griffith, M.D., or the Secretary, Franklin E. Murphy, M.D.

MARION-SIMS COLLEGE OF MEDICINE.

ST. LOUIS, MO.

This college will continue to offer a high class course of medicine in keeping with the facilities which the institution possesses. The laboratory instruction, clinic inctruction, didactic lectures and reviews and quizzes are utilized to their utmost.

The Rebekah Hospital, which is upon the college grounds, affords students an opportunity for witnessing a great variety of operations, while the City Hospital, Insane Asylum, City Almshouse, Pius Hospital, Lutheran Hospital and Grand Avenue Dispensary provide abundant clinical instruction.

The session begins Sept. 28, 1897, and ends April 10, 1898. Fees are as follows: Matriculation fee, $5; entire lecture fee, $50; final examination fee, $25; dissecting ticket, $10; chemical laboratory fee, $5; microscopic laboratory fee, $5; lecture ticket, for sons and brothers of physicians and sons of clergymen, $25; lecture fee for all courses, including matriculation, dissection and examination fee, if paid in advance, $150. Y. H. Bond, M.D., Dean; H. W. Loeb, M.D., Secretary.

MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE STATE OF MISSOURI.

COLUMBIA, MO.

Announcement.—Session opens Sept. 14, 1897. Length of term nine months. Fees, $20 for first year and $50 each for second and third years. Good board at the university clubs at $2 per week. Laboratories are the leading feature of this department. They consist of physics, chemistry, biology, physics, anatomy, pathology and bacteriology. All laboratories are conducted by able men, living upon adequate salaries, and *not* practicing, but giving their entire time to teaching and investigation.

Requirement for admission, in lieu of a diploma from a literary or scientific college or high school, is an examination in each of the following branches: History, English (on the grade of Longman's "School Grammar"), mathematics (algebra), Latin (equal to one year in a high school).

For further information address A. W. McAlister, M.D., Dean of the Faculty.

ST. LOUIS MEDICAL COLLEGE; MEDICAL DEPARTMENT OF WASHINGTON UNIVERSITY.

ST. LOUIS, MO.

Session begins Sept. 23, 1897, and ends April 28, 1898.

Our laboratories are well equipped and admirably adapted for the comfort and instruction of 400 students. Our clinical facilities in medicine are of the best, and include our clinics, private hospitals and a full share of work in the city institutions.

Many years' experience as an advanced school of high standard has perfected the curriculum. Henry H. Mudd, M.D., Dean, 2604 Locust Street; John B. Shapleigh, M.D., Secretary, 2608 Locust Street.

UNIVERSITY MEDICAL COLLEGE.

KANSAS CITY, MO.

Recognizing the advantage derived from an extended course of study, the graduates of this College are required to pursue the study of medicine at least four years, and must have attended three full courses of lectures.

The clinical advantages, offered the student by the various hospitals of the City, attract to this College matriculates from every State of the Union.

The teaching corps comprises no less than forty teachers who are men of recognized ability in their departments.

The course of study begins Sept. 14, 1897, and continues six months, and the cost of the general lecture ticket, including all laboratory and practical work, is $75.

As the faculty consists of members who constitute the staff of the various hospitals, it offers the student unusual opportunities for special study in each department. C. F. Wainwright, M.D., Dean; John Punton, M.D., Secretary.

JOHN A. CREIGHTON MEDICAL COLLEGE.

OMAHA, NEB.

The next term in this institution begins September 28, and will open under the most favorable auspices as the new building (one of the best in the country) has just been completed and furnished and equipped for teaching medicine according to modern ideas.

This college has exceptionally fine clinical advantages, having exclusive control of the clinical material in the St. Joseph's Hospital (a hospital of 300 beds). Being situated in the heart of the city the dispensary clinics are also very large. Two internes are appointed (by competitive examination) to St. Joseph's Hospital, from the graduating class. The course is a graded one consisting of four terms of seven months each. Large and thoroughly equipped laboratories offer unsurpassed advantages for the study of histology, pathology, bacteriology, etc. The anatomic rooms are large, well lighted and ventilated, with plenty of material always on hand. D. C. Bryant, M.D., Secretary.

OMAHA MEDICAL COLLEGE.

OMAHA, NEB.

The Omaha Medical College will enter upon its seventeenth annual session October 1, next.

The course is graded, extending over four years of seven months each. The system of instruction embraces didactic and clinical lectures, recitations, laboratory work in chemistry, histology, pathology, bacteriology, physiology and anatomy.

The facilities and equipment are thoroughly up to date. The building is new and has lecture-room and laboratory capacity for 250 students. A well patronized out door dispensary is connected with the College.

Clinical instruction is given in the Omaha, Clarkson, Immanuel, Douglas County and Presbyterian Hospitals, in all of which the staffs are made up from the College faculty.

The fees are $65, for each course, and a $30 examination fee divided among the different years.

Dissecting material is abundant. W. O. Bridges, M.D., Secretary, 1623 Douglas Street.

ALBANY MEDICAL COLLEGE.

MEDICAL DEPARTMENT UNION UNIVERSITY.

ALBANY, N. Y.

Four years' strictly graded course. Instruction is by lectures, recitations, laboratory work, clinics and practical demonstrations and operations. The Faculty is composed of thirteen professors, assisted by five adjunct professors, three clinical professors, six lecturers and seventeen instructors. Hospital advantages are excellent. Fees: Matriculation, $5 each year; lectures $100 per session; laboratory courses, $50; graduation fee, $25. Regular winter season begins September 28; commencement the third Tuesday in April. For catalogues and further information, address Willis G. Tucker, M.D., Registrar, 4 Lancaster Street.

BELLEVUE HOSPITAL MEDICAL COLLEGE.

NEW YORK CITY.

The new College building, which will be occupied before the close of the session of 1897-98, will afford much larger facilities for teaching than have hitherto been enjoyed by the College and will provide additional lecture rooms, laboratories and rooms for section teaching, dissections and demonstrations. The lengthening of the session to thirty two weeks and the extension of time of study from three to four years will enable students to devote more time to laboratory work than heretofore.

The collegiate year now consists of thirty-two weeks, with the usual holidays, beginning Sept. 27, 1897. The fees for lectures for each year remain at $150. Since the last session some important changes have been made in the arrangement of the Faculty, and in additions to the corps of teachers.

THE BROOKLYN POST-GRADUATE SCHOOL OF CLINICAL ELECTRO-THERAPEUTICS AND ROENTGEN PHOTOGRAPHY.

BROOKLYN, N. Y.

This clinic is intended to practically supplement the study of theory and electrophysics by instructing the physician how to treat patients with electricity—how to prescribe, dose, and apply all forms of medical currents, and operate and properly care for apparatus.

The plan of instruction recognizes the value of time to post-graduate and visiting students, and aims to impart the useful essentials of technique as quickly as possible. Therapeutic technique with galvanic, faradic and static currents will be demonstrated by object lessons without didactic lectures, all theory and physiologic instruction being prepared in printed form. Clinics Monday, Wednesday and Friday afternoons from September 17, to June 1. Term for course of three weeks in therapeutic technique $30. Single clinic $10. X ray complete instruction in manipulation of Crookes' tubes, demonstrating maximum effects, one session only required, $15. Special or particular courses of instruction arranged as desired to suit physicians with limited time. For further particulars address, S. H. Monell, M.D., 865 Union Street.

COLLEGE OF MEDICINE, SYRACUSE UNIVERSITY.

SYRACUSE, N. Y.

The college year begins on the first Tuesday in October and ends on the second Tuesday in June. It is divided into two terms about equal in length.

The annual tuition fee of $125 includes all laboratory courses and material, clinical clerkships, bone loan, microscopes, other laboratory instruments, library, reading rooms and other college appointments, for either instruction or the convenience and pleasure of the students.

Its building is new and large with the latest and best equipments, including a generous cold storage plant furnishing wholesome anatomic material at all seasons.

Its graduates are among the most successful candidates for license before the New York Examining Board. Chancellor Upson of the Regents, unsolicited says: "It it admitted by all competent judges to be unsurpassed in this State."

LONG ISLAND COLLEGE HOSPITAL.

BROOKLYN, N. Y.

The regular term for session 1897-98 will commence Sept. 29, 1897, in the new Polhemus Memorial Clinic.

Send for announcement, after June 10, to J. H. Raymond, M.D., Secretary of Faculty, Long Island College Hospital, Brooklyn, N. Y. Alex. J. C. Skene, M.D., President.

MEDICAL DEPARTMENT, NIAGARA UNIVERSITY.

BUFFALO, N. Y.

The Faculty is composed of twenty-one professors, three associate, three adjunct professors, six lecturers, one demonstrator and eight instructors and assistants.

Every student must attend an extended course in the laboratory of pathology, histology, chemistry and bacteriology.

Especial attention is given to bedside instruction and no student can report for graduation until he has successfully cared for at least seven cases of labor.

Clinical material is obtained from twelve hospitals and two dispensaries. Term begins Sept. 28, 1897; commencement exercises May 11, 1898.

Fees: Registration fee, to be paid each year, $5; general course of instruction, one year, $75; dissection (first two years) each year, $10; histologic laboratory, $10; pharmacal laboratory, $5; chemic laboratory (first two years) each year, $10; pathologic laboratory, $10; bacteriologic laboratory, $10; examination fee, each year except senior year, $5; examinations, senior year, $15.

President, John Cronyn, M.D.; Registrar, Alvin A. Hubbell, M.D.; Secretary, Harry A. Wood, M.D.

NEW YORK POLYCLINIC MEDICAL SCHOOL AND HOSPITAL.

A CLINICAL SCHOOL FOR GRADUATES IN MEDICINE AND SURGERY.

NEW YORK CITY.

The session opened Sept. 15, 1897. The lecture rooms immediately adjoin the wards, thus enabling the students not only to witness the operations but the after-treatment. The hospital contains seventy-nine beds, chiefly occupied by surgical and gynecologic cases. In the various dispensary classes 200 patients a day are treated.

Faculty: Surgery, Professors Wyeth, Fowler, Dawbarn, Van Arsdale and Townsend. Medicine, Professors Page, Kaztenbach, Van Valzah and Adler. Gynecelogy. Professors Munde, Gill Wylie, Goffe, Pryor and Krug. Diseases of children, Professors Holt and Seibert. Diseases of the skin, Professors Robinson and Bronson. Diseases of the nose, throat and ear, Professors Gleitsmann, Pomeroy, Myles, Asch and Sheppard. Diseases of the eye, Professors Webster and Marple. Diseases of the mind and nervous system, Professors Grey and Sachs. Obstetrics, Professor Ayers.

General ticket, $100 for six weeks; $150 for three months. For further information apply to W. R. Townsend, M.D., Secretary.

THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

NEW YORK CITY.

This institution has just entered upon its sixteenth year. Five hundred and thirteen physicians from all over the continent have attended the courses at the institution during the past year. More than one thousand operations were performed in the Hospital, which is one of the largest in the city, containing special wards for babies and children, while about twenty thousand patients were treated in the outdoor department. Recent discoveries have revolutionized medical and surgical methods and a man whose medical education ended fifteen years ago is not a physician or surgeon within the present meaning of the term. Post-graduate medical instruction is for the purpose of furnishing to these graduates in medicine a means of refreshing their knowledge. It supplies them with the opportunity of coming in direct contact with disease by means of special courses in all the departments of medicine and surgery.

THE NEW YORK SCHOOL OF CLINICAL MEDICINE.

NEW YORK CITY.

This school, which was organized less than two years ago in order to meet in our own country the demand for individual post graduate instruction, which hitherto was obtainable only in Europe, is enjoying unprecedented success. The work is wholly clinical. Matriculates are admitted into the classes as assistants, and are thus placed in direct contact with the patients, to examine and treat them, assist at and even perform operations under the guidance of the professors, who are all well-known specialists in their several branches. Only three or four physicians are received into each class—as many as the teacher can personally instruct. Fees are from $10 to $25 per course. The courses are four weeks in length.

UNIVERSITY MEDICAL COLLEGE (MEDICAL DEPARTMENT OF NEW YORK UNIVERSITY).

NEW YORK CITY.

The session begins on Thursday, Sept. 30, 1897, and continues until May 18, 1898.

The curriculum consists of a four years' graded course. Instruction is given by lectures, recitations, clinical and bedside teaching and laboratory courses. The four years' course obviates the overcrowding which obtained under the previous system.

The University Medical College is entitled to utilize, for clinical teaching, its quota of the vast quantity and variety of clinical material of the great city hospitals, viz., Bellevue, City Maternity, Gouverneur, Harlem, almshouse, workhouse, Incurables, Randall's Island, Fordham.

Fees; Matriculation, $5; fee for all required exercises of the year (including dissection, laboratory courses, physical diagnosis, operative surgery and practical obstetrics), $175 a session.

THE WOMAN'S MEDICAL COLLEGE OF THE NEW YORK INFIRMARY FOR WOMEN AND CHILDREN.

NEW YORK CITY.

The Woman's Medical College of the New York Infirmary for Women and Children, 321 East 15th Street, was founded in 1865 by Drs. Elizabeth and Emily Blackwell.

The college course is four years, beginning October 1; fees for the entire course, $515. Instruction is by lectures, recitations and practical work in laboratories, and by clinics in the Dispensary and Infirmary connected with the College. During 1896-97, 13,640 patients were treated in the Dispensary and 752 in the Infirmary. Operations and clinics in the city hospitals are free to students of this College. Emily Blackwell, M.D., Dean.

NORTH CAROLINA MEDICAL COLLEGE.

DAVIDSON, N. C.

The North Carolina Medical College has recently completed a new brick and granite building which will add very much to the efficiency of the work done. Class room work and thorough drilling in the fundamentals are the special features of this school. The length of term is eight months.

Tuition fee $75; matriculation $5.

THE CINCINNATI COLLEGE OF MEDICINE AND SURGERY.

CINCINNATI, OHIO.

The Cincinnati College of Medicine and Surgery opens Sept. 27, 1897, and continues seven months. The fees are $75. Special attention is given to laboratory and clinical methods during a four years' graded course. Hospital instruction is at the City, St. Mary's and the Jewish Hospitals. Two hours daily are given to clinical work at the College. *Women admitted.* W. E. Lewis, M.D., Secretary, 409 E. Fifth Street.

THE CLEVELAND COLLEGE OF PHYSICIANS AND SURGEONS.

MEDICAL DEPARTMENT OF THE OHIO WESLEYAN UNIVERSITY.

CLEVELAND, OHIO.

The College opens Sept. 22, 1897. Women are admitted on equal terms with men.

The course is four years, of eight months each; general ticket $100. This includes all expenses except the examination fee and a small sum for material used in the laboratories. The laboratories are all splendidly equipped, and presided over by the most competent teachers.

The medical management of the Cleveland General Hospital is in the hands of the Faculty. This Hospital is one of the most liberal, and has the largest patronage in the wards and dispensary of any institution in the city. The didactic and clinical lectures of the senior year are all delivered in the amphitheater of this building, thus affording students an opportunity to see practically all the emergency cases, both medical and surgical, that are admitted. Joseph F. Hobson, M.D., 429 Prospect Street.

LAURA MEMORIAL COLLEGE.

CINCINNATI, OHIO.

The College has been partially endowed, and is therefore not dependent upon the fees of students for its proper support.

The course consists of four years, of seven months each, each session beginning October 1 and closing May 1.

The students have exclusive access to the clinics and wards of the Presbyterian Hospital. They also attend the clinics at the Cincinnati Hospital, and have bedside instruction at the same institution.

The laboratories are all new and perfectly appointed. A special feature is a pharmacologic laboratory for experimental research, and a laboratory in skiagraphy.

The general lecture fees are $50 per year.

Graduates of the institution have exclusive opportunity for interneships in the Presbyterian Hospital, and may enter the competetive examination for interneship in the Cincinnati Hospital and in Christ Hospital. John M. Withrow, A.M., M.D., Dean.

THE MEDICAL COLLEGE OF WESTERN RESERVE UNIVERSITY.

CLEVELAND, OHIO.

This school graduated its first class in 1844. Its course in medicine is four years, of eight months each.

The requirements to enter are practically the same as for entrance to Adelbert College, the literary-scientific college of the university. The requirement for graduation with the degree of "Doctor of Medicine" is, that every branch included in the course shall have been completed to the satisfaction of the Faculty of the college and trustees of the university. This college has large hospital and dispensary clinical opportunities; large and thoroughly equipped laboratories; teachers in theoretic branches who devote their entire time to teaching, and who themselves have had high training and experience as teachers. It has (annually) thirteen hospital appointments at its disposal, with others open to its students on competition.

For information as to the cost of the course see advertisement in JOURNAL. G. C. Ashmun, M.D., Dean.

MIAMI MEDICAL COLLEGE.

CINCINNATI, OHIO.

The Miami Medical College of Cincinnati, a member of the American Medical College Association, has a course of four years, with a seven months' term each year. The fees are: Matriculation $5, paid once; lecture fees, annually, $100; Cincinnati Hospital ticket, annually for three years, $5. The special advantages of this school are its excellent facilities for clinical instruction. Twelve members of the faculty deliver bedside and amphitheater lectures at the Cincinnati Hospital, the great general municipal hospital, and the college has under its own control the Miami Maternity Hospital—a free lying-in hospital—and the Ophthalmic Hospital Building where are held its own general and special clinics on medicine, surgery, ophthalmology, otology, laryngology, gynecology, dermatology and neurology. A. P. Dundridge, A.M., M.D., is Dean; Joseph Eichberg, M.D., Secretary.

OHIO MEDICAL UNIVERSITY.

COLUMBUS, OHIO.

The phenomenal growth of the Ohio Medical University is a source of pride to those who have labored to the end of establishing a strictly high grade institution. For this success due credit must be given to the university system of teaching adopted in all departments, which has proven far superior to the old lecture plan with final examinations.

The curriculum covers four years' work, in terms of seven months each, with requirements for admission and graduation fully abreast with the highest grade colleges.

Clinical facilities are abundant, the various hospitals connected with the university furnishing during 1896, 462 medical and 816 surgical cases. This does not include 30 obstetric cases and special clinics at the Ohio Penitentiary and State Hospitals.

STARLING MEDICAL COLLEGE.

COLUMBUS, OHIO.

The fifty first annual course of lectures will commence on Sept. 15, 1897, and continue until April 13, 1898.

The course is graded and covers a period of four years. Instruction is given by lectures, recitations, clinical teaching and practical demonstration.

Thorough laboratory instruction is given in histology, anatomy, chemistry, physiology, bacteriology, pathology, embryology and biology.

The requirements for graduation conform to the standard of the State Board of Medical Examination and the Association of American Medical Colleges.

For catalogue or fuller information address Thos. C. Hoover, M.D., Registrar, 249 E. State St.

TOLEDO MEDICAL COLLEGE.

TOLEDO, OHIO.

The seventeenth annual session of the Toledo Medical College begins Sept. 30, 1897. Four courses of six months each are required. The new and commodious college building, four stories high, has every equipment and modern convenience. It is situated between the Toledo and St. Vincent Hospitals, one square from each, the former with 100, the latter with 200 beds, and has full use of both, also of the Woman's Retreat and Foundling's Home. It has a continuous free dispensary with a large clinical attendance. The fees are $50 for general ticket, or $175 for four or more years. Considering the individual instruction possible in a school of its size, no more thorough course in medicine can be obtained anywhere. Wm. J. Gillette, M.D., Secretary.

UNIVERSITY OF CINCINNATI.

DEPARTMENT OF MEDICINE, MEDICAL COLLEGE OF OHIO.

CINCINNATI, OHIO.

The Medical College of Ohio during the past year became the Medical Department of the University of Cincinnati, but retained the name which it has held since its foundation by Daniel Drake in 1819. The new building contains the lecture halls and the laboratories, which have been splendidly equipped. A thoroughly modern clinic building has been erected on the grounds and has proved to be admirably adapted for its purpose.

The course consists of four years of seven months each. The fee of $100 includes all required laboratory work and dissections. The clinical advantages are very great and positions in six of the hospitals are open to graduates of the college. W. W. Seely, A.M., M.D., Dean; James S. Hyndman, M.D., Secretary, 22 W. Ninth St.

MEDICAL DEPARTMENT, UNIVERSITY OF OREGON.

PORTLAND, OREGON.

The Medical Department of the University of Oregon is located in the city of Portland, is a member of the Association of American Medical Colleges, its requirements being those laid down by that organization. Since 1896 it has been a four course school. It has a corps of well qualified instructors, there being fourteen professors and eight adjunct lecturers. The chemic and bacteriologic laboratories and dissecting department are specially complete.

Good Samaritan, St. Vincent and the Multnomah County Hospitals are utilized for clinics, which are frequent, and the material varied and abundant.

The fees are graded according to class entered. Matriculation is $5, fee for each course varying from $130 to a free ticket for the fourth year to those who attend all four courses in this school; examination fee is $30. S. E. Joseph, M.D., Dean.

MEDICAL DEPARTMENT, WILLAMETTE UNIVERSITY.

SALEM, OREGON.

The Medical Department of Willamette University is permanently located at Salem, the capital of the State, and is now entering upon its thirty-second year. The course of instruction continues through four years, in accordance with the highest and best standard of modern advancement.

The regular course of instruction will begin on Wednesday, September 29, and continue for six consecutive months. Students must conform to the requirements of the Association of American Medical Colleges for matriculation and graduation.

Fees: First year, matriculation fee, $5; lecture fee, $100; demonstrator's fee, $5; breakage fee in laboratory (returnable if not used), $3. Second year, lecture fee, $100. Third year, lecture fee, $75. Fourth year, lecture fee, $20; examination fee, $30. W. H. Byrd, M.D., Dean.

THE JEFFERSON MEDICAL COLLEGE.

PHILADELPHIA, PA.

The course is a graded four years' curriculum. It consists of didactic lectures and recitations by the faculty, laboratory work under the charge of a large corps of demonstrators and assistants, and clinical lectures in every special field, with ward classes conducted in the college hospital. The institution is provided with its medical hall and museum, its laboratories, recently much enlarged and fitted out at great expense, and its hospital, where over three hundred patients are treated daily. The maternal department maintained in a separate building, utilized over two hundred cases of midwifery last year for the instruction of the graduating class. The winter course lasts nearly eight months.

The annual fee is $150, the matriculation fee, $5 (paid but once). No diploma fee. J. W. Holland, M.D., Dean.

THE MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA.

PHILADELPHIA, PA.

This college enters upon its seventeenth year October 1. The results of open competitive examinations and of those of the State Examining Board have shown beyond question that its graduates can hold their own with the most favored institutions. The completion of the new clinical amphitheater, the finest and largest in the country, greatly adds to the facilities for clinical teaching, upon which together with laboratory training the college lays special claim to superiority. Other marked improvements have been made and, most important of all, the addition to the faculty staff of several well known and skilled instructors will be a guarantee that the institution will maintain its position in the forefront of American medical colleges.

The tuition fees range from $145 for the first year to $100 for the fourth.

PHILADELPHIA POLYCLINIC AND COLLEGE FOR GRADUATES IN MEDICINE.

PHILADELPHIA, PA.

Practical individual instruction, clinical and demonstrative, is given to physicians only, during the entire year.

The post-graduate department offers opportunities for observation and study, alike to experienced practitioners who desire to acquaint themselves with the most recent developments in medical science and art or to take up special lines of practice, and to recent graduates who wish to become particularly familiar with medicine and surgery in its dispensary and the methods employed in hospital wards.

Courses may begin at any date. The fee for any one branch is $15. A general ticket for all clinical branches, $90. M. J. Stern, M.D., Secretary.

UNIVERSITY OF PENNSYLVANIA, DEPARTMENT OF MEDICINE.

PHILADELPHIA, PA.

The one hundred and thirty-second annual session will begin Friday, Oct. 1, 1897, at 12 M., and will end at commencement, the second Thursday in June.

The curriculum is graded, and attendance upon four annual sessions is required. College *graduates* in arts or sciences who have pursued certain biologic studies, are admitted to advanced standing.

Practical instruction, including laboratory work in chemistry, histology, osteology and pathology, with bedside instruction in medicine, surgery, gynecology and obstetrics, is a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to John Marshall, M.D., Dean, Thirty-sixth Street and Woodland Avenue.

WESTERN PENNSYLVANIA MEDICAL COLLEGE.

MEDICAL DEPARTMENT OF THE WESTERN UNIVERSITY OF PENNSYLVANIA.

PITTSBURG, PA.

This college offers graded courses of eight months, session of 1897–98, twelfth year, commencing Oct. 5, 1897.

Four years required for graduation. Instruction eminently practical. Clinical facilities afford advantages to students. *New* college and clinical buildings with extensive laboratories freshly stocked with every needed appliance in all departments. Hospital operative clinics, maternity clinics and dispensary out-door clinics are given daily. Laboratory work is continuous. Quizzes given regularly. For particulars address T. M. T. McKennan, M.D., Secretary, 524 Penn Avenue.

WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA.

PHILADELPHIA, PA.

The forty-eighth annual session opens Sept. 29, 1897. A four years' graded course of lectures, quizzes, bacteriologic and clinical work offers superior advantages. Students are admitted to the clinics of city hospitals. Address Clara Marshall, M.D., Dean, 1712 Locust Street.

MEDICAL COLLEGE OF THE STATE OF SOUTH CAROLINA.

CHARLESTON, S. C.

This College, founded in 1828, offers a three years' graded course, good hospital advantages, well equipped chemic, pathologic and bacteriologic laboratories, modern dissecting room, excellent teaching facilities and ample clinical material. Every facility afforded for a thorough course of instruction by lectures, demonstrations, quizzes, laboratory work and frequent clinic.

Lectures begin Oct. 1, 1897. Commencement exercises April 1, 1898.

Fees: First year, matriculation $5, lectures $100, laboratory fee $5; second year, lectures $100, laboratory fee $5; third year, lectures $80, laboratory fee $5. No further charge for dissecting and hospital ticket or diploma fee.

Women admitted to medical and pharmaceutic courses.

For catalogue and other information address Francis L. Parker, M.D., Dean, 70 Hassell Street.

CHATTANOOGA MEDICAL COLLEGE.

MEDICAL DEPARTMENT OF GRANT UNIVERSITY.

CHATTANOOGA, TENN.

On September 15 the College opens the regular annual course of instruction. The session will continue twenty-six weeks of actual teaching. It has an ample teaching corps of twenty-three instructors, with six well equipped laboratories and such clinical facilities as can only be afforded by a population of a city of this size. It promises to its patrons a splendid opportunity for a thorough preparation for the practice of medicine. The fees are reasonable ($50 for professor's ticket), having been arranged so as to encourage the worthy young man in his efforts to obtain a medical education. Through the three year graded course the student receives all positive instruction possible by placing special emphasis upon individual laboratory training, as well as by didactic lecturing and recitations. J. R. Rathmell, A.M., M.D., Dean; G. Manning Ellis, M.D., Secretary.

MEHARRY MEDICAL COLLEGE.

NASHVILLE, TENN.

The twenty-second annual session of Meharry Medical Department of Central Tennessee College, Nashville, Tenn., will open Sept. 13, 1897.

This institution is designed for the education of colored physicians, and more than half of the regularly educated colored physicians of the Southern States are numbered among its alumni. It has a graded course of study of four sessions. The College has well equipped laboratories and good clinical advantages are furnished. There are fifteen members in the faculty. One hundred and fifty-two students were enrolled the past session.

For catalogues or further particulars address G. W. Hubbard, M.D., Dean.

MEMPHIS HOSPITAL MEDICAL COLLEGE.

MEMPHIS, TENN.

This College was organized in 1878, and has more than 1,200 graduates.

Its corps of instructors consists of ten professors, fifteen assistants and a full corps of quiz-masters to carry on free quizzes and reviews.

The fees are $75 for full set of tickets, including all laboratory work.

The length of term is six months, beginning in October and closing the last of the following March. It possesses clinical advantages in two hospitals, in addition to the College Dispensary, which latter has over 4,000 patients each session. The attendance for the session of 1896–97 was 316 students, the largest number of regular medical students that attended any Southern college.

For further information address W. B. Rogers, M.D., Dean.

SEWANEE MEDICAL COLLEGE, UNIVERSITY OF THE SOUTH.

SEWANEE, TENN..

This College is now engaged in its sixth annual course of lectures extending from June to the ensuing January.

The present class is exceedingly encouraging both in numbers and quality, and gives assurance of a grand success.

The requirements, rigidly exacted, are for entrance, ample preliminary education, and for graduation, attendance upon three annual courses of lectures.

The elevated mountain location of the institution insures health, comfort and favorable conditions for study during the summer and fall seasons.

The establishment of a charity hospital, now in preparation, with sanitariums and an out-door department, will furnish the much needed clinical facilities and render the equipments perfect.

The college fees, per session, are from $55 to $65; graduation fee, $25. For information address J. S. Cain, M.D., Dean.

TENNESSEE MEDICAL COLLEGE.

(MEDICAL AND DENTAL DEPARTMENT.)

KNOXVILLE, TENN.

The Faculty embraces eighteen professors and seven lecturers and demonstrators. The session for 1897–98 begins Oct. 1, 1897, and ends April 1, 1898.

Fees: Medical department, $65; dental department, $100, per session. Three years' attendance is required.

Members of the Southern Medical Colleges Association, National Association of Dental Faculties and National Board of Dental Examiners.

All departments are equipped with the most modern appliances. Temperate climate; a medium between the extreme North and the South. J. C. Cawood, M.D., President.

UNIVERSITY OF NASHVILLE, MEDICAL DEPARTMENT.

NASHVILLE, TENN.

Throughout the south and southwest, for nearly half a century, the name of this institution has stood for superiority in medical education. Though well along in middle life, progress continues to be the watchword. The new college building is complete in every appointment for the most modern and thorough instruction and the personel of the faculty such as to commend and retain the confidence of all.

From present indications the coming session promises to be the most successful in the history of this school. William L. Nichol, A.M., M.D., Dean.

UNIVERSITY OF TENNESSEE, MEDICAL DEPARTMENT.

NASHVILLE, TENN.

Preliminary term opens September 6. Regular session begins October 4. Commencement will be held the latter part of March, 1898.

This college gives a three years' graded course.

The instruction consists of didactic lectures, clinical teaching, practical instruction and examinations or quizzes.

From four to five didactic lectures are delivered daily. Two clinical lectures are given daily, one in the City Hospital and one in the clinical amphitheater at the college.

Clinical facilities: The City Hospital, Davidson County Hospital and the College Dispensary clinics.

Laboratory courses in chemistry, microscopy, bacteriology, pathologic anatomy and surgery are compulsory.

Practical anatomy, laboratory work and clinical instruction are emphasized, and ample facilities for their study are provided. Fees: First year $100; second year, $100; third year $115. For information address Paul F. Eve, M.D., Dean, 614 Broad St.

VANDERBILT UNIVERSITY, MEDICAL DEPARTMENT.

NASHVILLE, TENN.

This institution has had twenty-three years of prosperity. In building, equipments and teaching corps she easily stands among the first of the medical schools of the land. Through the influence of his wife, Commodore Vanderbilt was induced to establish a university in the South. He selected Nashville as the most suitable location for such an institution. To his princely gifts the late William H. Vanderbilt added largely. The first department of the Vanderbilt University to begin work was the Medical Department. Her alumni, numbering now about 2,600 are to be found in various parts of the country and many of them are already famous as medical men.

UNIVERSITY OF TEXAS, MEDICAL DEPARTMENT.

GALVESTON, TEXAS.

The Medical Department consists of the Schools of Medicine, of Pharmacy, and of Nursing. The School of Medicine offers instruction under twenty competent specialists, extending over a period of four years, leading to the degree of M.D. Women are admitted.

Tuition in all departments of the university is free. A matriculation fee of $30, payable but once, is charged.

The session begins October 1. The school possesses a complete equipment. For information address, Geo. T. Winston, M.D., President.

MEDICAL DEPARTMENT OF THE UNIVERSITY OF VERMONT.

BURLINGTON, VT.

With its forty-fourth session, beginning in January, 1898, and continuing until July, this school inaugurates the four year system of graded study as a requisite for graduation. The Mary Fletcher Hospital affords ample clinical facilities. Laboratories for chemic, histologic and bacteriologic work; an abundance of anatomic material, and apparatus for surgical and obstetric manikin practice are provided. Entrance examinations are required before matriculation. The Faculty *includes eminent specialists from distant cities.* The number of students last session was 253; graduates 53. The annual lecture fee is $100: examination, $25; matriculation, $5. Address B. J. Andrews, M. D., Secretary.

MEDICAL COLLEGE OF VIRGINIA.

RICHMOND, VA.

The Medical College of Virginia is one of the oldest and best known medical institutions in the South. Extensive additions have recently been made whereby its facilities have been much extended. The City Free Dispensary and Old Dominion Hospital, under the control of the Faculty, adjoin the College. Dental and pharmaceutic departments have recently been established and will be in operation at the opening of the coming session. The Faculty (Christopher Tompkins, M.D., Dean) consists of eighteen professors and nineteen lecturers, demonstrators and instructors. The course of instruction covers three sessions of seven months each, but will most probably be extended to four next year. Fees for each session, $90. The session began on Sept. 21, 1897.

UNIVERSITY COLLEGE OF MEDICINE.

RICHMOND, VA.

This institution, with Hunter McGuire, M.D., LL.D., President, is now in the fifth year of its existence. Twice since its establishment the building has been enlarged, and now extensive buildings are being added for laboratory purposes, etc. When completed at the opening of the next session, September 30, the institution will have accommodation for 500 students.

It embraces three degree-conferring departments, medicine, dentistry and pharmacy, each with independent Faculties, the whole teaching staff consisting of fifty-one professors and instructors. There were 274 students last year.

The course is a well graded one and consists of three terms of eight months each; the tuition fees for the whole course in medicine being $225. This institution has the benfit of the clinical material afforded by two hospitals and two dispensaries.

UNIVERSITY OF VIRGINIA, MEDICAL DEPARTMENT.

CHARLOTTESVILLE, VA.

The session began September 15 and will continue nine months. The course of study extends over three full sessions, and is graded as follows: 1., Chemistry, biology, descriptive anatomy. 2. Physiology, bacteriology, pathology, regional anatomy, materia medica, obstetrics. 3. Gynecology, surgery, therapeutics, practice, ophthalmic surgery, hygiene and medical jurisprudence.

The utmost attention is paid to securing accurate instruction. The practical work is done under minute individual supervision. The tuition fees for the three years amount to $120, $100 and $60 respectively. The other necessary expenses are from $25 to $35 per month.

The University of Virginia is situated in the beautiful and healthful region of Piedmont, Va. For fuller information apply for catalogue to P. B. Barringer, M.D., Chairman of the Faculty.

THE SOUTHERN MEDICAL COLLEGE ASSOCIATION.

[Received too late for insertion on page 632.]

The Southern Medical College Association makes the following requirements, viz.:

Every student applying for matriculation must possess the following qualifications:

He must hold a certificate as the pupil of some known, reputable physician, showing his moral character and general fitness to enter upon the study of medicine.

He must possess a diploma of graduation from some literary or scientific institution of learning, or certificate from some legally constituted high school, General Superintendent of State Education, or Superintendent of some County Board of Public Education, attesting the fact that he is possessed of at least the educational attainments required of second-grade teachers of public schools; provided, however, that if a student, so applying, is unable to furnish the above and foregoing evidence of literary qualifications, he may be permitted to matriculate and receive medical instruction as other students, and qualify himself in the required literary departments, and stand his required examination, as above specified, prior to offering himself for a second course of lectures.

The foregoing certificate of educational qualifications, attested by the Dean of the medical college attended, together with a set of ticket showing that the holder has attended one full course of medical lectures, shall be essential to attendance upon a second course of lectures in any college belonging to the Southern Medical College Association.

1 189—

Dean of . . . . :

DEAR SIR—Mr . . . . . . of . . . . . . , is a gentleman of good moral character. I recommend that he be allowed to enter upon his medical studies in your college. He has been my pupil . . months.

Yours, [Sign here]. . . . . M.D.

---

2 189- -

Dean of . . . .

DEAR SIR—I have examined Mr . . , of . . . . . and find his scholastic attainments equal to those requisite for a second-grade teacher's certificate in our public schools.

Yours, ...

Supt. of Pub. Instruction.

WISCONSIN COLLEGE OF PHYSICIANS AND SURGEONS.

MILWAUKEE, WIS.

The next session in this school will begin on Wednesday, September 15, and continue until March 29, 1898. Attendance upon four full courses of lectures is required before graduation. The annual dues including laboratory deposits amount to about $80. The laboratory and clinical facilities of this institution are fully up to the requirements of the present advanced state of medical science. W. H. Washburn, M.D., Secretary.

SOCIETY PROCEEDINGS.

British Medical Association.

Proceedings of the Section on Public or State Medicine at the Sixty-fifth Annual Meeting, held at Montreal, Canada, August 31 to September 4, 1897.

WEDNESDAY—SEPTEMBER 1.

The Section convened at 10 o'clock, A.M., in the lecture room of the Redpath Museum, President E. P. LACHAPELLE, M.D., Montreal, in the Chair.

Among those present from the United States were Drs. Benjamin Lee of Philadelphia; C. O. Probst of Columbus; Felix Formento of New Orleans; Henry D. Holton of Brattleboro, Liston H. Montgomery, Arthur R. Reynolds and N. S. Davis, Jr., of Chicago; Lt.-Colonel Alfred A. Woodhull, U. S. A., and Murray G. Motter of Washington, D.C.; G. D. N. Hough of New Bedford, Mass.; E. C. Rivers of Denver, Colo.; Wolfred Nelson of New York, and J. C. Shrader of Iowa City, Iowa.

Dr. LACHAPELLE, after extending a hearty greeting to the Section, read a résumé or synopsis of his paper entitled

THE PROGRESS OF SANITATION IN CANADA.

The speaker analyzed all the sanitary legislation in Canada from the time of Louis XIV. to the present, and the hygienic measures under the French régime, 1603 to 1763. Thus in 1667 the King of France established for the Civil State a system of registration of births which is still in force in the Province of Quebec. The same law appertains also to baptisms, marriages and burials. In 1667 the question of food was considered and as a first step in this direction the inspection and price of bread was decided upon. In 1707 meat had to pass inspection regulations equivalent to our modern stamping. In 1748 there were regulations relative to foundlings until they were 18 or 20 years of age.

Following this he spoke of the typhus fever epidemic of 1795 in Ireland, which demanded the urgent protection of the colony and vessels coming from infected ports and the manner in which they were inspected and quarantined. From 1815 to 1821 the government appointed medical vaccinators and granted prizes for a memoir on the advantage of vaccination, etc. In 1832 hygienic measures received a stimulus by the appearance of cholera and a quarantine station was established at Grosse Isle. In 1849 more precise laws were adopted, because of a second invasion of this disease and since the Confederation (1867 to 1897) positive systemization has prevailed in the provincial governments throughout Canada.

Regarding Federal sanitation, all matters relating to foreign countries and to commerce are of Federal jurisdiction and accordingly sanitary laws were passed at Ottawa in reference to immigration and quarantine, the prevention of contagious diseases in animals, the suppression of food adulteration, the compilation of statistics, etc.

In the first year of the Confederation (1868) the Federal government enacted an "Immigration Act" destined to be completed (1871) by the "Quarantine Act," and rendered most effective subsequently. Mention was made of the eight well organized quarantine stations of the government, viz., Grosse Isle, Quebec; Halifax, Nova Scotia: St. John, N. B.; Sydney, Cape Breton; Hawkesbury, Nova Scotia; Chatham, N. B.; Charlettetown, Prince Edward Island, and William Head, B. C., including a detailed description of how the various staffs of these ports see to the inspection and disinfection of vessels, to the vaccination of passengers, to the detention in quarantine when required, etc.

Regarding contagious diseases in animals, the federal station (1884–1896) provides for the quarantining of exported animals and for the repression of epidemics among them.

The "Adulteration Act" appoints food analysts, to whom any person may submit samples; it also has some provisions respecting milk supplies and other foods (1884–1889).

As to provincial sanitation and municipal authority regulations the law varies in different Provinces. Certain Provinces, such as Manitoba and British Columbia, possess special organizations, while in the Northwest Territories and Prince Edward Island there are no provincial boards of health, although there exist sanitary laws investing extended powers in the Lieutenant-Governor in council and in the municipal authorities. In a word, hygienic laws in the Northwest Territories are adapted and elastic as occasion requires. Ontario and Quebec are perhaps the best managed Provinces. The Provincial Board of Ontario was founded in 1882; that of Quebec in 1886. These two boards have enabled public hygiene to make the greatest progress in Canada. In Ontario compulsory vaccination of all children over four months of age has been provided for by the statute and school teachers may require a certificate of vaccination from pupils. The Provincial Government has the entire control of vital statistics (1896), the compiling being done by the secretary-treasurer of each municipality. Here also the Food Act is very explicit in cities. In the Province of Quebec vaccination is obligatory by statute in four cities, but any other municipality may render it compulsory. The keeping of the registers of the civil state is still, as in the days of Louis XIV., confided to the care of the clergy of whatsoever denomination and it is from these gentlemen that each month the Provincial Board of Health receives the certificates establishing the causes of death and those reporting the marriages and births. From these reports the Board compiles its statistics. The Provincial Board has power to make regulations to supplement in a certain measure the federal laws. In relation to the prevention of contagious diseases, hygiene in factories, sanitation in general, including the suppression of nuisances, etc., the Quebec Provincial Board has issued permanent and very precise regulations and has formulated in them a standard of effectiveness that must be attained by the municipal boards. Apart from these permanent regulations it has, besides, the eventual powers of making special regulations during the prevalence of epidemics.

In both Ontario and Quebec the Provincial Boards may exercise the power conferred upon the local boards if such local boards neglect or refuse to perform their duties.

In Ontario the interpretation and the enforcing of the "Factory Act" is left entirely to the inspectors.

The appoval of plans of aqueducts and drainage devolves on the Provincial Board in the Provinces of Quebec and Ontario. In Quebec the law regulates the disposal of the dead and enacts that the sites for cemeteries shall be chosen by the Provincial Board.

Speaking of other Provinces briefly: New Brunswick (1887) and Nova Scotia (1893), possess somewhat identical organizations. The Lieutenant Governor in council having the right to legislate on sanitary matters, but only in Nova Scotia can the Lieutenant-Governor exercise his veto. The sanitary laws of New Brunswick (1887–9) very much resemble those of the Province of Quebec, as they confer on the Provincial Board the power to make regulations respecting the prevention of contagious diseases, the inspection of food and of insalubrious industries, drainage and the repression of nuisances. The registration law (1887) provides for the publication of vital statistics. In Nova Scotia, the authority of the Provincial Board with regard to contagious diseases is simply advisory. It may, however, during an epidemic, substitute itself for inefficient municipal boards. Manitoba (1893) admits of a special organization which seems to suit the needs of a country whose population is disseminated over a vast area of territory. Its Provincial Board is composed of five members, a veterinary surgeon and four physicians. For the needs of local administration, the four physicians are titled inspectors, and the Province is divided into four districts. In each district the authority of the inspector is supreme. British Columbia has (1895) a Provincial Board which according to the statute seems to be only advisory, but which nevertheless has established very complete and very effective regulations; for instance it has a measure which surpasses those of any other Province, prohibiting the discharge of sewage into any river. Prince Edward Island has no Provincial Board. It has a gool law respecting vaccination, and by its "Health Act," local boards are appointed in two cities, and the Lieutenant-Governor in council is empowered to appoint a board of health in each county. In the Northwest Territories a law relating to hygiene was passed in 1882. Its means are only preventive. The Lieutenant Governor can hinder any person within the Territories from leaving a locality in which there exists a contagious disease. He can also delay at the frontiers any suspicious outsider. He can divide up the Territories into sanitary districts, and appoint medical health officers if he judge such measures expedient.

The regular order of scientific business was then proceeded with.

Dr. P. H. Bryce read a paper,

HOW FAR SHOULD MANDATORY MEASURES GO IN DEALING WITH: 1, MEASLES; 2, WHOOPING COUGH; 3, TUBERCULOSIS; 4, LEPROSY; 5, CHICKENPOX.

A brief analysis of his paper is as follows:

In Ontario the law, so far as it relates to chickenpox, is a dead letter on account of the mildness of the disease. Regarding measles, in 1894, sixty-five cases died in the entire Province of Ontario; in 1895, forty-one cases; in 1896, forty-three cases.

The writer assumed that the public is not prepared to be quarantined for this disease, as the gravity of the disease will not warrant it. Notwithstanding this, he recommended the following rules for school children for measles or whooping cough: 1. Daily notification to the health office, by the school authorities, of every absentee. 2. The truant officer should visit the home of the child immediately, for investigation. 3. A visit by a medical man to diagnose the disease if any exists. 4. Compulsory notification by the household (this will readily corral the disease, and practical isolation be made at once). 5. Notification, by the teacher, of any further cases of disease occurring in the school, and their immediate removal. 6. Home isolation by means of placards. 7. Disinfection of the house. 8. Closing of the school as a last resort.

Regarding whooping cough, it is contagious long before "cough" has shown itself, or where spasmodic coughing takes place.

As tuberculosis causes more deaths than any other disease, insist on notification of all cases of this kind being made to the health office. Insist on the regulation of the tubercularized, viz., to remain at home, to remain away from factories, etc. Establish hospitals or homes or sanitaria throughout the Province for them.

Leprosy cases need to be isolated.

Dr. C. O. Probst said that we are in the dark as to the cause of whooping cough, yet we can prevent the spread of the disease. He called attention to the fact that in the eleventh census of the United States, 9,256 cases of measles died, 8,432 cases of whooping cough, fifteen cases of leprosy, while 102,199 died from consumption. It is difficult to prescribe mandatory laws in the control of measles and whooping cough, as public opinion is against it. Although we should require notification of whooping cough, yet we have no isolation hospitals for such cases. Apparently, then, notification may not amount to a great deal. Closing the public schools does not protect the children unless the disease is epidemic. The prevalence of these diseases is due to their mildness. He advocated double notification referred to, placarding the homes of the sick and other domiciliary measures. In leprosy, he was in favor of the National Government establishing a place for the segregation of lepers. In tuberculous subjects we can not, unfortunately, isolate these cases. Their sputa should be disinfected. In tuberculosis of lower animals we can enforce mandatory measures in the sale of unsound meat and impure milk, or slaughter the diseased animals when found so by the tuberculin test. There is a close connection between breathing impure or foul air and consumption. Capitalists and others must be made to perform their duty and those in authority should be held responsible.

Dr. H. Handford of England was not in favor of mandatory measures for these mild types of disease. In England many think there is too much legislation already. We need in this branch of medicine in England a Minister of Health.

In scarlet fever the removal of a case can be made compulsory by a magistrate's order, but in his city of 250,000 inhabitants he does not think that such an order has ever been issued. He advocated education and persuasion of the parents on the part of the attending physician, that their confidence may be gained and a case removed voluntarily. Health officers are inclined to be looked upon as officious. He was, however, in favor of mandatory or compulsory measures regarding the disposal of impure milk and impure meat; as in England there are laws governing this, also governing tuberculosis. Leprosy is a clinical curiosity in England. He thinks that what applies to whooping cough applies practically to measles, although in measles the mortality varies greatly. In cities 43.05 deaths in every 1,000 cases occur, while but 6 cases in every 1,000 cases of measles die in country districts; in some cities in England, however, the mortality may reach 49. Notification in England is required by law, and it is a double notification, both by parents and teachers.

Dr. William Oldright of Toronto agreed in part with the last speaker. He thinks we lose sight of much of the educational idea, but he thinks compulsory measures are also necessary. He said that whooping cough is more dreaded than measles in some families and cited a number of illustrations in support of his statement. Regarding tuberculosis, as a usual thing it is not properly dealt with. Rooms at health resorts frequented by tuberculous patients should be more thoroughly disinfected. The same rule holds good regarding the disinfecting of rugs, carpets, etc., in sleeping-cars and hotels, which should be washed oftener; as a rule, this is rarely done.

More isolation hospitals should be established for scarlet fever and diphtheria cases, and with these comes in the mixed infection class; when we come in contact with such a case, where one variety is exposed to the other the case may become more complicated. If placarding is done it should be thorough and not inefficiently. Placards on milk wagons, stating that the dealer deals only in pure milk, is a strong inducement for the people to patronize such firms.

Dr. Ebenezer Duncan of Glasgow thinks tuberculosis is the most important of these diseases to combat. He believes the greatest amount of good can be obtained by increasing the cubic space for breathing pure air and that overcrowding should be condemned. If thorough ventilation is carried out there is not much chance of infection; good feeding should go with this, then notification in case of death. He did not think it was possible to carry out effective mandatory measures with regard to measles and whooping cough.

Dr. Thomas Carr of Braintree, England, urged the necessity of disinfecting the sputa of tuberculous cases. Regarding measles and whooping cough we are not yet ready to isolate these cases in a large district. In 80 per cent. of the towns in England where notification has been tried, it has been abandoned.

Dr. Alexander Johnson of Glasgow—If we attempt to remove cases of measles or whooping cough to isolation hospitals, the plan is likely to fall through and then we are placed in an unfavorable light. Public sentiment is with the people in this matter. Measles is scarcely at all contagious after the eruption has appeared. In whooping cough it is more infectious when the secretions or sputa are abundant and such cases should by all means be isolated.

Dr. Wolfred Nelson of New York—Leprosy is in no sense contagious. I have seen the disease in the Island of Trinidad and the Isthmus of Panama and have known sisters of charity to nurse the disease twenty-six years and be in constant attendance and not a single case developed among them. It is simply a newspaper sensation to state that this malady is contagious, and as intelligent medical men we should add no additional burdens to these unfortunates by sending them away from their former surroundings and family.

Dr. Benjamin Lee of Philadelphia replied to the last speaker by saying or inquiring, if leprosy is not contagious, in what manner do you account for its propagation from person to person? The health authorities of Cape Colony have recently published an exhaustive report on the prevalence of leprosy in that country, in which they strongly sustain the doctrine of contagion. Negative testimony may wipe out positive testimony, although not reliable.

Dr. John A. Macolmson of Middleborough, Eng., thought we could advance public health matters best by educating the people concerning all kinds of disease.

Dr. Felix Formento of New Orleans concluded the discussion by referring to the cases of leprosy he had seen in his city. The disease seemed to be transmitted by heredity or contagion.

Dr. James T. Neech of Atherton, Eng., read a paper on

THE PERIOD OF INFECTION IN SCARLET FEVER.

He thought six weeks too short a period for the specific poison, infection or microbe to cease to multiply, even though desquamation may be complete. Infectivity can be retained in the fluids of the body indefinitely. Complete elimination in the shape of spores is not secured by the emunctory organs. According to his experience the minimum period of contagion is four to eight weeks; the maximum period six months; the average is thirty-nine to sixty-five days. He has known cases discharged from hospitals, as in the above periods of time, convey the disease. He believes the infection is stored up in the secretions of the nose, lungs, lymphatic glands, etc. He had obtained bacteriologic results in hospital cases at the expiration of eight weeks and even thirteen weeks, and he cited one hospital case of 181 days' convalescence wherein the disease had been conveyed. In all cases he advocated that the clothing should be sterilized by steam.

Dr. Johnston of Glasgow, in the discussion, thought eight weeks for hospital cases a short enough time in which a patient could be deemed free from the germs of the disease, and even then his clothing [illegible] be [illegible] and dis[illegible] [illegible]withstanding [illegible]es, 2 per [illegible] infection away with them. He cited an illustration of this kind, that had been in the hospital for three months and then discharged cured, that infected and spread the disease through an entire household. He suggested that these cured cases should be required to sleep alone for two or three months.

Sir James Grant of Ottawa said that formerly, when there was no sewerage he could trace the origin of scarlet fever to defective drainage. If he should attend a case of scarlet fever he should not think of attending a case of obstetrics short of six weeks. His idea is that the kidney gives the most trouble. The period of infection is not thoroughly defined yet, for the disease may be propagated for a very indefinite period.

Dr. Malcolmson recited a case of infection of scarlet fever that had been retained in a hospital fourteen or fifteen weeks that spread the disease after being discharged as cured. The result was that the health authorities were sued and a heavy judgment was obtained.

Dr. Adam Frederick John Mickle of Christ Church, New Zealand, said: It is not desirable to keep children in a town hospital for too long a period after convalescence from scarlet fever. As soon as convalescence is well established, say in three weeks, and sometimes earlier, they should be removed to the country, as complete recovery will be much quicker in a pure atmosphere; other means can be used to eliminate the poison or infection, such as hot baths; these will hasten the period of complete recovery. Regarding the danger of attending midwifery cases, while attending a case of scarlet fever, I do not think the danger so great as it is usually believed to be. During a very severe epidemic of scarlet fever lasting nine months, which I had to contend with about twenty years ago, I also attended midwifery cases in considerable number and never had any bad results. If asepsis is carried out there is no danger. In some instances the children were laid down with scarlet fever in a room with the mother, where she was confined, and yet I did not see a bad result in a single case of midwifery during the whole epidemic, notwithstanding the scarlet fever swept the children like a plague in the first few weeks of the epidemic. This was doubtless due to the insanitary condition of the town, which was practically without drainage, and the houses being small and on the Scotch system of flats, there was much overcrowding and, lastly, people will not submit to too much isolation.

CADAVERIC FAUNA

Was the subject of an illustrated paper read by Dr. G. de N. Hough of New Bedford, Mass. He divided the said fauna into: 1, workers of the first stage of putrefaction; 2, workers of the second stage; 3, workers of the third stage; 4, consumers of the dried tissues; 5, consumers of the remains of the other workers. These parasites were given in their respective orders of diptera, coleoptera, lepidoptera, etc.

UNDERGROUND ZOOLOGY AND LEGAL MEDICINE.

A study of 150 disinterments with additional experimental observations, by Dr. Murray Galt Motter of Washington, D. C. The author had experimented and made his observations on bodies that were buried from one year and eleven months up to seventy-one years. The subject is a new one and his paper, medico legally, very interesting. He proved the same kind of beetles, flies and other insects and germs had been found upon bodies whether they had been buried in June or in January, which would disprove the theory that a body supposed to have been buried in either of these months was in reality buried six months subsequently or previously, as the case might have been. He found tetanus germs active after the body had been buried three years.

SELECTIONS.

Medical Education in Canada.—"The general question of medical education is one of great importance and of unceasing interest, nor is this interest confined to the profession; it is becoming universal. The needs of medical education are fortunately being more fully realized by those who on account of their wealth and influence are in a position to render that substantial assistance which is so requisite. The time was when every medical school was a purely proprietary concern 'run' for the money that was in it. We feel in Canada, and I think I can speak for the profession in the neighboring republic, that this day is passed, that high-minded philanthropists like Sir Donald Smith (now Lord Strathcona and Mount Royal), the late John Henry Molson, the McDonalds, the Drakes and others with us, and the Johns Hopkins, the Stanfords, the Vanderbilts, the Rockefellers, the Miss Garretts and others with them are beginning to realize that unendowed instruction in medicine must lead to imperfect results, and that private endowment, in the absence of state aid, has become an absolute necessity to a proper medical training. I am not an advocate for state aid to universities, and I rejoice that the University to which I have the honor to belong is not so dependent, as it might thus be deprived of those gifts of private munificence to which I have just referred. All honor to those far-seeing, open-handed men and women who are giving of their abundance in order to elevate the standard of medical education and by so doing benefit their kind. As Gould very tersely puts it in one of his clever articles: 'I think our reliance must be upon private bequest, and these can be secured only as we interest the rich. We must never weary in showing the neglect of the greatest, most palpable, most certain means of doing good. There is a strange fatality in men, an unaccountable inability of seeing the need that lies nearest, the good that is dearest. There is more money today devoted to astronomy than to the prevention of disease. It is positively wonderful to think that men should be more interested in stars and constellations than in their bodies and their physiologic life.' A question which is now-a-days agitating the minds of those especially interested in medical education is the kind of ground-work which is likely to bear the most direct relation to the future studies of the medical student. I think it is now conceded by all that he is placed at a greater advantage who first passes through an arts or a science course. I am happy to be able to report that from 15 to 20 per cent. of those who are studying medicine in this country today have had a collegiate training in either arts or science. Which of the two should the parent or guardian choose? Had I a son whose instincts were in the direction of medicine I think I should choose for him the science course. The late Professor Huxley thought it was a most self-evident proposition that the educational training for persons who proposed to enter the medical profession should be largely scientific; not merely or even principally because an acquaintance with the elements of physical or biologic science is absolutely essential to the comprehension of human physiology and pathology; but still more because of the value of the discipline afforded by practical work in these departments in the process of observation and experiment, in inductive reasoning and in manipulation. . . . What deters so many from taking a full course in Arts or Science before entering Medicine is the length of time consumed before the doctorate degree is reached, although I hope the time is not far distant when every graduate in medicine in Canada shall of necessity be also a graduate in arts or science. . . . We have in the Dominion of Canada no fewer than eleven medical schools, including one for women only, all having the power of granting degrees and all connected directly or by affiliation with university bodies. To enumerate them: Beginning with the Atlantic Provinces, we have in Halifax the medical school attached to Dalhousie University, the only medical school in the Maritime Provinces; in this province there are four schools, Laval in Quebec, Laval in Montreal, McGill and Bishop's in Montreal; in Ontario, four schools, namely, the Royal College of Physicians and Surgeons, Kingston; the University of Toronto Medical Faculty, Trinity Medical College, and the Ontario Woman's Medical College, in Toronto; in London, Ontario, the Western University Medical Faculty; and lastly, in Winnipeg, the Manitoba University Faculty of Medicine. All told, we had in Canada, during the last winter sessions 286 teachers, including professors, lecturers, and demonstrators, and 1736 students. The tendency for the past few years has been to increase the teaching staff quite out of proportion to the increased number of students. Taking McGill we find that there are in the present year 53 teachers for 388 students, being a proportion of nearly one to eight. Laval, in Montreal, has 36 teachers and 197 students, a still greater proportion. The Toronto School of Medicine had during the past year 41 teachers and 293 students. We find that this proportion compares well with the larger schools in the United States; thus, in 1893, there were in Harvard Medical School 71 teachers to look after 471 students; at the Columbia Medical College in New York with 661 students there were 105 teachers (1 to 6); in the University of Pennsylvania the teaching staff in the same year comprised only 84 members with 825 students, being a little over 1 to 10. What does this mean? Ten years ago when McGill had 237 students, a staff of 23 professors and demonstrators was considered sufficient. Why are so many more thought necessary now-a-days? The number of subjects are differently taught, the old fashioned daily didactic lectures are now given two or three times a week only; but I should be sorry to see them further reduced in number, for I believe that so many are absolutely necessary. It is in the dissecting room, the chemic, physiologic, therapeutic and pathologic laboratories that we see the change. These which before were for the most part only 'side shows' are now made to hum with the practical work which is done within them. . . .

"In order to make the clinical instruction more complete and more thorough, chemic and bacteriologic laboratories have been added to the pathologic departments of our hospitals. . . . The question sometimes arises, however, May the student not be getting too much of a good thing? Is it not possible that laboratory teaching may be overdone? because, as Welch very truly says, 'The student whose knowledge of a subject is derived exclusively from laboratory courses is likely to lose his perspective in details, to acquire only a fragmentary knowledge of the subject, to fail to comprehend the general bearing of observed facts, and not to acquire the general principles and systematic conceptions which are essential. Laboratory work should be accompanied and supplemented by the reading of text books and by lectures.' I am convinced that with us in Canada laboratory work is not overdone, but, on the contrary, in some departments needs and deserves further encouragement. I hope every laboratory teacher in the country realizes that the object of a college is to give a good general education, and not to make experts in various branches. I have long felt myself, however, that the didactic lectures were being unfairly dealt with. There is a feeling abroad that they should be practically elbowed out of sight. I think the didactic lecture has its place in the medical course; and while I quite feel that the old plan of compelling students to listen to five didactic lectures a week in all of the great subjects was a mistake, I still feel that a good lecturer can teach in this way a certain something which can not be imparted by practical instruction or by recitations. The personal influence of a good lecturer very often makes an impression which nothing else can make; and if such lectures are made also demonstrative, as by the use of diagrams, the lantern, experiments, etc., they must of necessity fill a very important place in the medical course. . . . The facilities for clinical teaching in the larger cities of Canada are admirable. Speaking for the city of Montreal, we have in the five general hospitals, the Hotel Dieu, Montreal General, Notre Dame, Royal Victoria and Western Hospitals, nearly 800 beds. The number of students attending the three medical schools was last session 646; and considering that only about half—those of the third and fourth years—have access to the wards, there will be at least two beds for each student. The number of outdoor patients attending the five hospitals daily would aggregate at least 300, so that there can be no possible cause for complaint regarding both the quantity and quality of clinical material available in this city."—T. G. Roddick, M.D., M.P.

A National Memorial to Jenner.—A meeting was recently held in London to establish a memorial to the great Jenner, with the Duke of Westminster as chairman. Lord Herschell, late president of the Royal Commission on Vaccination, in moving the first resolution, "That the present is an appropriate time to inaugurate a work of national utility in honor of Edward Jenner," said that a hundred years ago smallpox was periodically committing ravages which we could now hardly realize. Jenner introduced to the world his discovery that inoculation of cowpox would prevent attacks of the disease, and at the end of the first quarter of the century a marked change was seen not only in this country, but in many of the countries of Europe. From the outset there had been those who doubted the efficacy of vaccination, and the Commission on the subject, over which he presided for many years, had just issued its report. A vast amount of material was considered, and it fell to his lot to have to digest that material, analyze it, and submit a report for the consideration of his colleagues. When he approached that task he approached it with the determination to follow the results to which the facts led, whatever they might be, and he was surprised at the force of the evidence in favor of vaccination. From the "Blue Book" he quoted figures in favor of vaccination which, he said, it was difficult for human reason to resist. Jenner's character and veracity had been attacked by some people who pointed out that he asserted or expected that vaccination would be permanent in its effects, while everybody now admitted that absolute permanency did not exist. The only way to tell whether it would be permanent or not was by experience, and those who availed themselves of the experience of a century of vaccination, to assail Jenner, who necessarily did not possess that experience, were the same persons who very often refused to yield to the teachings of experience when they inquired now what had been the effects of vaccination. Jenner was the first to illustrate a principle which seemed destined to play an important part in the history of preventive medicine. Surely this alone was a high tribute to Jenner and the value of his discovery. His name was held in reverence by the highest men of science and the most civilized countries in the world. Some of those countries had commemorated his centenary. Jenner was an Englishman and were Englishmen to be behindhand in testifying their admiration of the man and their sense of the benefits he had conferred on humanity? Prof. Michael Foster who seconded the resolution, said he would like to re-echo the words of Lord Herschell and claim for Jenner's work scientific merit. Except, perhaps, for the fact that the labors of Dr. Monckton Copeman and others tended to minimize the dangers of vaccination, relatively little progress had been made in the principles laid down by Jenner till the time of Pasteur. Jenner was governed by the idea we now call the doctrine of attenuation, a doctrine revived by Pasteur and which had become the basis of our great progress at the present time. Lord Lister took occasion to correct a mistake which he made in his presidential address to the British Association at Liverpool. The mistake, he said, had been made a very great deal of in the newspapers, and had been taken advantage of by the antivaccination party in distributing a leaflet to that meeting. The statement was to the effect that smallpox was absolutely unknown in the German army as a result of the revaccination of all recruits. He had quoted from memory after reading an authority on the subject and if he had stated that "fatal" smallpox was absolutely unknown in the German army he should have been speaking the literal truth. Such being the case, he did not think it necessary to rectify in a public manner the mistake he had made when a letter appeared in the *Times* calling attention to this mistake. He had since obtained the official documents from which the writer of this letter had taken the facts to convict him. Now he asserted that from 1874-75 to 1886 87 the only death from smallpox that occurred in the German army was that of a man who was proved not to have been properly vaccinated. If, instead of deaths, he took the cases, in 1886-87 there were 7 out of 344,000 men, in 1885-86 there were 6, in 1884-85 there were 7, and so on. He thought, therefore, he had not made any very serious blunder after all. The writer of the letter had also contended that vaccination had had no influence whatever in diminishing the death rate from smallpox in the German army. He (the speaker) had examined the official statistics and found that from 1874 75, when the Compulsory Revaccination Law was passed, the mortality from that cause in the army had become absolutely *nil*. Not only so, but, as a German authority himself had been lately saying, Germany might now be said to be practically free from smallpox. He was glad to take this opportunity of correcting his mistake, because it enabled him to support the principle of vaccination from German statistics. He pointed out the value of research on the lines laid down by Jenner, giving as examples Dr. Koch's treatment of rinderpest in South Africa, M. Haffkine's inoculation in connection with the bubonic plague, the experiments of Dr. Yersin, and the results obtained by the use of antidiphtheric serum in this country, which had saved a multitude of young lives.—*Lancet*.

On the Teaching of Surgery.—The address presented to the Section on Surgery at the recent meeting of the British Medical Association by Christopher Heath, F.R.C.S., called attention to the remarkable recent progress in abdominal surgery. Twelve years ago neither appendicitis nor Kraske's operation for removal of the rectum was mentioned in the "Dictionary of Practical Surgery," and Kraske's original paper was only published in 1885. In British surgery appendicitis dates from a paper read by Treves before the Royal Medical and Chirurgical Society in February, 1888. In speaking of the infrequency of perineal lithotomy today he said: "Looking back over forty years of professional life, nothing surprises me more than the change which has come over the treatment of calculus. In my student days, to see Fergusson cut for stone by the lateral method was to witness an operation as near perfection as was conceivable, and the dexterity and rapidity with which the calculus was extracted was only marred by the frequency with which death from septic causes spoiled the skill of the surgeon. To have one's first lithotomy was an event in the life of the young surgeon, and every now and then a reputation was spoiled by some *contretemps* in the public performance of the operation. Later, I was the frequent witness of my colleague, Henry Thompson's skill in using the lithotrite to break up the calculus in a series of 'sittings.' Then came 'litholapaxy,' or rapid lithotrity, which we owe to Bigelow, the great American surgeon; and lastly that recurrence to the old high or suprapubic operation which was due to the Scandinavian surgeon, Petersen. Hence the student of today rarely, if ever, sees a perineal lithotomy, and as a consequence his interest in the anatomy of the parts concerned in the operation has greatly diminished." Teachers in anatomy find it difficult to secure neat dissections from the student as various museums contain excellent preparations in spirit, a condition of affairs to be deplored in that the essential to advance in surgery is a working knowledge of anatomy. In Great Britain also anatomic teaching is getting more into the hands of anatomists who are not surgeons, and other than surgical relations care thus emphasized. The same being true in physiology and chemistry, when these gentlemen happen to become examiners this tendency to specialize becomes very marked, and the unfortunate medical student becomes the victim of science (falsely so called), and sometimes develops into that marvelous being, a London B.Sc.

Bacterioscopic Work on the Bacillus of the Plague.—Dr. Wilson of the Hoagland Laboratory, Brooklyn, has for some time been engaged upon experimentation as to the viability of the plague germs. The culture with which his experiments were made was obtained through the kindness of Dr. W. F. Arnold, U. S. Navy, who obtained it from Yersin in China, and brought it directly to the United States, renewing it at San Francisco. Upon obtaining the culture, it was transferred to suitable media, and test was made as to its virulence on susceptible animals such as guinea-pigs, mice and rabbits; the results showed that it was still very virulent. The method used was that of Sternberg. A series of 5 c.c. cultures in beef tea were made in tubes of a uniform shape and size, and these were allowed to incubate for twenty-four hours. They were then exposed for ten minutes (a previously ascertained time being allowed to bring the temperature of the culture up to that of the bath) in a water-bath at the following temperatures: One at 50, one at 52, one at 54, one at 56, one at 58 and one at 60 degrees C. From each one, after cooling down to the temperature of the room, transfers were made into fresh beef tea, and these transfers placed in the incubator. After twenty-four hours in the incubator, it was seen that the ones exposed at 50, 52, 54, 56 and 58 degrees showed a good growth. The one at 60 did not grow. Another series was started at points between 53 and 60, with the result that the ones at 58, 58.5, 59 and 59.5 showed a growth, while the one at 60 did not grow. This would seem to fix the normal death rate at 60 degrees C. or about 140 F., for ten minutes' exposure under moist heat. It was decided to use infected articles of different absorbing properties, and consequently different degrees of dessication, so as to approach the natural conditions as nearly as possible. Cover-glasses, pieces of filter paper and small pieces of wool blanket, were chosen for these reasons, and also because the same articles were used in the cholera experiments in 1892. These articles were first sterilized and then infected, each piece with a drop of a twenty-four hour bouillon culture. They were then left in a dark closet over night to dry, and the next day placed in an oven. Every hour a piece of glass, paper and blanket was removed and tested as to its vitality. Dr. Wilson's experiments showed that the bacillus died out before the end of the first hour on the glass; before the end of the fourth, on the paper; and was living at the end of the sixth hour, on the blanket. Experiment was also made to ascertain how long the bacillus would survive on the glass, paper and blanket at the temperature of the rooms (21 degrees C.) in a dark closet excluded from the action of the sunlight. A series of test-tubes was taken and their closed ends broken open. Pieces of cover-glass, filter paper and blanket were then placed in the tubes, the ends of which were plugged with cotton and then carefully sterilized. The object of this was to secure a normal circulation of air. The pieces of paper, glass and blanket were then infected, each with a drop of a twenty-four hour old culture, and the tubes placed in a dark closet. At intervals of seven days these infected pieces have been removed and placed in fresh media. On all these materials the bacillus has survived up to the date of this report, forty-two days. His conclusions were: 1. The thermal death-point of this organism is one or two degrees higher than that of the majority of pathogenic bacteria of the non-sporulating variety. 2. Differing widely from cholera, sunlight and dessication can not be relied on to limit the viability of this bacillus under commercial circumstances. 3. Rags, nails, ballast and general merchandise coming from infected ports should be subjected at either the port of departure or the port of entry to a thorough system of disinfection. Experiments have been made in this series of Dr. Wilson only with carbolic acid. It has been found that an exposure for two hours, to a 1 per cent. solution of carbolic acid, suffices to destroy the life of the bacillus. This observation has subsequently been confirmed by Kinyoun. The morphology, cultural characteristics and pathogenesis of this bacillus has never been carefully worked out under favorable laboratory surroundings. The details of this work will shortly be published. Dr. Wilson refers briefly to the researches of others, as follows: "Some work has already been done in this direction by Kitasato and Yersin, but it was done under adverse circumstances and the results obtained were not final. Kitasato found that cover-glass preparations of the contents of a bubo exposed to the air of a room at 23 to 30 degrees C. showed no growth after four days. Other cover-glass preparations exposed directly to the sun's rays showed no growth after three or four hours. He found that beef tea cultures heated for thirty minutes in a water-bath up to 80 degrees C., were destroyed. At 100 degrees C., in the vapor apparatus, they were destroyed in a few minutes. It will be seen that these experiments were made only with thin films; and in the first or dessication experiment no effort was made to exclude the sunlight, and in the second or sunlight experiment the film must undergo dessication at the same time."

PRACTICAL NOTES.

The Summer Diarrheas of Infants.—As the result of a bacteriologic and anatomic study of the summer diarrheas of infants, Booker (Johns Hopkins Hospital Reports, Vol. vi, 1897) reaches the following conclusions: 1. The conditions for the development of bacteria in the intestine of infants affected with summer diarrhea are different from those obtaining in the healthy intestine of milk-fed infants. These conditions are favorable to more varied bacterial vegetation, to a richer growth of varieties of bacteria, found inconstantly and in small numbers in the healthy intestine and to a more uniform distribution through the intestine of the two constant varieties of milk-feces bacteria: the bacillus lactis aerogenes and the bacillus coli communis. 2. No single micro-organism appears to be the specific exciter of the summer diarrhea of infants, but the affection is generally to be attributed to the result of the activity of a number of varieties of bacteria, some of which belong to well-known species and are of ordinary occurrence and wide distribution, the most important being the streptococcus and the proteus vulgaris. In the superficial epithelium of the intestine is apparently to be found the chief protection of the mucosa against the invasion of bacteria. 3. The pathologic lesions found in the intestine and other organs of the body in the summer diarrheas of infants indicate that bacteria exert a direct injury upon the tissues in some instances, whereas in others the damage is brought about indirectly through the production of soluble poisons. 4. The pathologic lesions of the inflammatory forms of summer diarrheas of infants are of a serious nature and show great variety. In many cases the intestinal lesions are very extensive, not infrequently much of the thickness of the mucosa being entirely destroyed; in other cases the intestinal lesions are slight and the more serious damage is recognizable in other organs. The number of organs that may be affected and the variety of lesions furnish an explanation for the great variation in the clinical features and the difficulty experienced in making a reliable prognosis. 5. When the summer diarrhea of infants passes into an inflammation of the stomach and intestine it is no longer a mere affection of the gastro-enteric canal, but a general infectious disease or intoxication in which other organs of the body participate, either as the result of an invasion of the body by bacteria, as is often the case in the lungs, or from the effects of poisons absorbed from the intestine, as occurs in other organs. 6. A correspondence between the clinical features and the bacteriologic findings and anatomic changes exists in many cases, so that three principal forms of summer diarrhea of infancy may be distinguished, viz., dyspeptic or non-inflammatory diarrhea, streptococcous enteritis and bacillary gastro enteritis. Dyspeptic diarrhea is free from the phenomena of inflammation and is characterized by lumpy, acid stools which contain no leucocytes or epithelial cells and have among the bacteria chiefly bacilli coli communes, with a few bacilli lactis aerogenes. This is the mildest form of summer diarrhea, but it frequently shows a tendency to progress further and it is often the first stage of the inflammatory forms of the disease. Streptococcous gastro-enteritis is characterized by symptoms of general infection, extensive ulceration of the intestine partaking of a suppurative character, frequent slimy stools which contain great numbers of leucocytes, with the predomination of streptococci, although it is rarely if ever a pure streptococcous infection. In a few instances streptococci so largely predominate in the wall and contents of the intestine that no other organism can be considered as having important bearing on the affection. In most cases there are a great number of bacilli with the cocci, and their activity is probably more or less felt, although the prevailing influence is exerted by streptococci. There is often a considerable difference in the course of the disease in cases having the characteristic features of a streptococcous infection, some patients responding readily to treatment, while others are not influenced by it in the slightest degree and continue steadily to grow worse until the disease reaches a fatal termination. It is probable that the streptococci found in these cases are not always of the same species, though no attempt has been made to differentiate between them. Bacillary gastro-enteritis is characterized by a general toxic condition, less extensive inflammation and ulceration in the intestine, more or less frequent watery or pasty stools, containing but few if any leucocytes and in which bacilli greatly predominate. It is, however, very seldom that one variety of bacillus is so greatly in excess as to preclude the attaching of importance to the presence of other organisms. As a rule a number of varieties of bacilli and some streptococci are found. In typical instances any one of these three forms of the disease may be easily recognized, but there are many transitional cases which apparently do not belong to any one of these forms and which are probably due to a more decided mixed infection, in which no one bacterium especially predominates and the disease-phenomena are influenced by the activity of a number of varieties of bacteria. Little is known of the effect of alterations in the quantity and quality of the normal ferments and juices of the alimentary tract upon the digestive disorders of infancy, but there are grounds for the belief that such changes may be of important consideration in these affections.

Successful Extirpation of a Ruptured Spleen.—At a meeting of the Medical Society of Cologne Plücker (*Deutsche medicinische Wochenschrift*, Aug. 12, 1897, suppl., p. 154) reported the successful extirpation of a ruptured spleen by Bardenheuer. An analysis of the results of this operation shows that these were most unfavorable from removal of the leukemic spleen, with a mortality of more than 90 per cent.; then follow essential hypertrophy of the spleen, with a mortality of 57 per cent., malarial hypertrophy, with a mortality of 55 per cent., echinococcus cysts of the spleen, with a mortality of 40 per cent., and finally sarcoma of the spleen, with a mortality of 30 per cent. The total result was made the more favorable by the cases of simple cyst of the spleen and wandering spleen, which were operated on without a fatality. A plea was made for conservative surgical treatment, especially for simple cysts and wandering spleen. Open wounds of the spleen offer a favorable prognosis, whereas subcutaneous injuries are very often fatal. Of the latter, injuries of the malarial spleen are to be separated from those of the healthy organ. Among twenty-four cases of rupture of the malarial spleen recovery ensued in six, while of twenty-eight cases with subcutaneous injury of the healthy spleen recovery ensued in two or three. The case reported occurred in a man 44 years old, who fell a distance of thirteen feet. When seen the patient presented symptoms of shock, with a small, running pulse and inaudible heart sounds. The sixth and seventh ribs on the left side were found to be fractured and crepitation could be heard. There was severe pain in the precordium. Under appropriate treatment improvement took place in the pulse and in the general state. On the other hand absolute dulness on percussion developed in the dependent portions of the abdomen upon the left side, extending upward to the axilla, but not involving Traube's semilunar space. There was also dulness posteriorly on the left side of the chest up to the level of the spine of the scapula, with bronchial breathing and diminished vocal fremitus. The urine was normal and the stools contained no blood. On the eleventh day the patient, who had been gradually improving, complained of sudden pain in the abdomen and in the precordium. The pulse was small and 140. Dyspnea was marked and diaphragmatic breathing was suspended. The abdomen was distended, but under appropriate treatment improvement took place. Exploratory puncture of the left side of the chest now disclosed the presence of blood. The temperature rose and tenderness and dulness on percussion in an area as large as the palm of the hand were found below the ensiform cartilarge. The heart was displaced upward and to the right. It was believed that rupture of a hemorrhagic extravasation had taken place into the subphrenic space with suppuration. Accordingly a trap-door flap, attached posteriorly, was turned back and the two lower ribs resected. The kidney was found intact. The peritoneum above was felt to be thickened and its division exposed a cavity filled with blood coagula, closed off below from the peritoneal cavity, and bounded above by the concavity of the diaphragm. In the midst of this hemorrhagic collection lay the spleen, almost double its normal size, with its capsule torn in several places. An attempt to bring the viscus into the wound was atten- [illegible] 'th rupture pedicle, without, however, notewc [illegible] hage.

ration had begun in the extravasation. The removed organ displayed a large oblique fissure from above downward on its concave aspect. At the hilum there was also a stellate laceration and the main vessels had been torn through. The large cavity was tamponed after removal of its contents. The further progress of the case was uneventful. The wound gradually closed and the patient bore the loss of his spleen well. Examination of the blood after the operation showed a diminution in the hemoglobin, without any alteration in the relation between the red and colorless corpuscles. In the course of two months there was a distinct increase in the number of colorless cells, and at the same time the peripheral lymphatic glands became enlarged. The thyroid, however, showed no change. The general condition was good. Further glandular enlargement did not take place, and that which was present grew less.

On the Local Anesthetic Use of Eucain.—Dr. P. Silex of the policlinic of Dr. Schweigger at Berlin, reports favorably concerning the ophthalmic use of eucain, in the *Therapeutische Monatshefte* for June. He says that a little more than a year ago Dr. Vinci introduced his first preparation to the attention of the surgeons at the policlinic and an investigation of its merits has been made during the year. "As a result of these trials I was enabled to say that the remedy is very useful, and preferable to cocain. A solution subsequently placed at my disposal from another source, which also bore the name eucain A, I was obliged to throw aside, as I previously stated, because it caused extremely violent pain in the lids, and very severe reddening of the conjunctiva. Consequently I found myself at variance with the opinion given by me at the time to my colleague Vinci. As, however, I observed equal care and precaution on both occasions, and there was no difference in the clinical material, I concluded that the solutions of eucain A were not the same, and that perhaps one was not so free from acid or something, as the other. Dr. Vinci was quite right when he wrote that the investigations in the clinic gave a good result; on the other hand I could not ignore the unpleasant symptoms which I subsequently observed. Respecting eucain B, I am now in the position to make a further favorable report. It has been employed for the last two and one-half months by Professor Schweigger in various operations on eyes, especially in forty-nine cases of senile cataract, with satisfaction. Anesthesia is complete, vascular injection is moderate. Corneal cloudiness does not appear, although it is necessary that instillation should be made as shortly before operation as possible. Four drops suffice within five minutes before the operation. If instillation of the ordinary 2 per cent. solution be too long continued, a very marked hyperemia of the conjunctival vessels appears, and on cutting through the conjunctiva the abnormal flow of blood may conceal the field of operation. Whether the vascular repletion favorably influences the healing of the wound is not yet decided, but in this respect the anemia caused by cocain was determined by Mellinger to have a deleterious effect. If it be necessary for any reason to anesthetize the iris, which can not be effected by the instillation of either cocain or eucain into the conjunctival sac, after incising the cornea a few drops can be injected into the anterior chamber by means of a broad-mouthed pipette. In two minutes at latest the iris becomes devoid of feeling, as I have convinced myself upon two rabbits, as well as in an operation upon a man for cataract."

Dangers in Lean Meat.—Practical experience, as well as theoretic considerations, lead to the conclusion that a lean meat diet continued for any length of time is incompatible with health. Leading medical teachers in France are sounding the note of warning against the use of an exclusive meat diet in diabetes, a disease for which lean meat was formerly supposed to be almost a panacea. A close study of the history of these cases has shown that an exclusive meat diet is not infrequently a cause of death, through the accumulation of so great a quantity of ptomains within the body that the kidneys are unable to cope with them. Professor Boofelt says: "It is the duty of the physician who places his patient upon a lean meat diet to inform him of the fact that he is living close to the border line, and that his situation is like that of a man walking along the brink of a precipice; that he must on no account submit himself to the influence of an anesthetic without first undergoing a few days' preparation, including an entire change of diet; and the truly wise physician will further instruct his patient that it can not be safely adopted as a continuous dietary without the risk of constitutional injury.—*Public Health Journal*, August, 1897.

Success of Stypticin in Arresting Uterine Hemorrhages.—Ten pages in the *Therap. Woch.* of August 8, are devoted to a classified review of forty-nine cases of hemorrhage from the uterus treated with stypticin (cotarninum hydrochloricum, obtained from "narcotin"), at Dr. S. Gottschalk's private gynecologic clinic in Berlin. The results in all but ten cases were "good" or "very good;" one "dubious," nine "nihil." He has had an equally favorable average in 120 cases thus treated to date, and considers it "ideal" in climacteric hemorrhages. If an immediate result is desired he injects a syringe of a 10 per cent. aqueous solution into each gluteus (total, 0.2 stypticin). But the usual method is per os, in pills, powders, gelatin capsules or drops, four to five times a day, each dose 0.05 gram. No inconveniences were observed from its use except in the case of one hysteric patient, who vomited and was unable to sleep after taking one powder. The price has fallen from 6 marks to 50 pfennigs per gram.

Stigmata of Degeneration in Epilepsy.—Dr. A. Ferree Witmer before the Philadelphia Pediatric Society, under head of morphologic deviations from normal, classed asymmetries of skull and face, dental anomalies, inflammations of the skin and marked pallor without organic disease. As functional deviations from normal, he noted retarded puberty, various anomalies of the menstrual function, gluttony, merycismus. For the purely psychic stigmata he applied severer tests, as directed to the attention, memory and association. He required the writing of as many words as possible in one, two and five minute periods respectively; from memory a spoken, written and a simple sentence when read, and as the last of the tentative series the writing down of the associations of some familiar word, *e. g.*, city, hospital, etc.

The Specific Action of Quinin in Malaria.—Dr. E. C. Register, of the *Charlotte Medical Journal*, stoutly maintains that malarial fever, without complications, will subside after the plasmodia disappears from the blood. After a close study of the crescentic and ring-shaped bodies, he says that the alleged failure of quinin is due to its imperfect absorption when given by the stomach and when the temperature is over 102 degrees. In continued malarial fever, if distinct intermissions are produced by antipyrin, acetanilid and phenacetin, the crescentic and ring-shaped bodies will disappear after the administration of quinin as readily as the spheric bodies in an ordinary case of intermittent fever.

Treatment of Non-Tuberculous Arthropathy with Artificial Venous Stasis.—Prof. A. Bier has found his "congestive treatment" of tuberculous joint affections so effective that he has been led to try it on others, and reports its success in various rheumatic and gonorrheal joint troubles, especially the more recent cases. The passive congestion of the part must be intense, and if swelling and blisters occur, so much the better for the result. As soon as the pain will permit, he applies passive movements to the joint, while continuing the constriction, followed by active movements and massage after the elastic band is removed.—*Semaine Méd.*, August 18.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
Per Annum, in Advance $5.00
Foreign Postage 1.75
Single Copies . . . . 10 Cents.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the *Editor*, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, SEPTEMBER 25, 1897.

FOREIGN MEDICAL TRAINING FOR RECENT GRADUATES.

The JOURNAL has already editorially deprecated the too general tendency to consider a brief European sojourn the correct culmination of an American medical education, regardless of the actual scientific profit thus to be derived. In this educational number it is worth while to offer a few words, in addition to what has already been said upon the subject, to emphasize certain points and to touch upon others that were not fully treated in the former utterances.

As has already been said there is an advantage to be obtained by the physician from foreign travel and study if the traveler is fitted by education and natural gifts to receive it. This is not always or even often the case with the recent graduate however, and there are some positive disadvantages in this fashion of ostensibly finishing off an American medical college course with a European trip. It is, in the first place, a direct disparagement of an American medical education in the eyes of foreigners, which a decent patriotic pride should make one wish not to offer; all the more, in view of the fact that as good a professional education can be obtained in any of our great medical centers as anywhere else on earth. Leading foreign teachers have remarked this and have expressed surprise at the prevalent fad, and their judgments were made up from actual knowledge of American medical teachers and teaching facilities and acquaintance at least by reputation with the eminent physicians that America has produced. Those who have most helped to make this reputation are mainly those who have established their own before making a European tour or who were specially prepared by education and training for obtaining the best that Europe could give them before leaving their own country to seek professional knowledge abroad. It would be well if our contribution of medical tourists were all of that type.

At present it is the fashion to visit German medical centers, as it is there that medical students have learned to look for the great lights in medicine at the present time. However this may be. the average American is at a positive disadvantage in Germany from lack of, or imperfect, acquaintance with the language, and without this it is hardly possible to see how he can profit by his German residence. Too often all he gains is a small stock of foreign affectations and an altogether undue valuation of the "made in Germany" trademark in medical matters. It usually takes the victim some little time to outgrow this and a few never quite succeed and suffer in consequence in the estimation of sensible people. It is true that the young physician may find that he obtains a slight prestige among a certain class of patrons by exploiting the supposed European polish his professional education had received, but this is a factitious advantage that is yearly losing its spell and it is doubtful whether the game is worth the candle.

Travel is said often to widen the views and broaden the culture, and so it may do, provided the individual is fitted by training and has the leisure and opportunity to obtain what benefit can be obtained in this way. One can best obtain this benefit when he is thoroughly prepared by having already had what culture could be given him in his own country, for this is a case where the saying "to him that hath shall be given," is most emphatically true. Medical culture follows the same rule and it can be safely assumed that the average recent graduate is hardly yet in the situation to derive the most advantage in a professional way from a residence abroad. He should first, at least, learn the language of the country to which he goes and have some general acquaintance with its medical literature. No medical college course, however thorough, can insure him these accomplishments; they come from prior and after study, and a knowledge of foreign medical literature is scarcely to be attained until after graduation. With it, a foreign tour is largely a superfluity, but it can be made all the more profitable to the tourist. With a fair knowledge of European medical literature the American physician has a great advantage over the average foreigner, who as a rule knows little of what is done in scientific medicine in this country.

In all our great medical centers there are ample opportunities for the graduate student to acquaint himself with the best results of the best work in all languages, not merely that of Germany, which by no means includes everything, and this almost or quite without expense. There has been a great advance in this respect within the past twenty years, and any actual necessity of going abroad to complete one's medical education certainly does not now exist, whatever may have been the case in former years. As regards scientific culture from foreign travel, it is to be hoped that the time will soon come when European physicians will see it to their advantage to visit this country and study our methods and facilities of medical instruction, and that a real reciprocity will come to be the rule in matters of this kind. In the meantime we can, in probably a majority of cases, consider a medical graduate's foreign tour as a pleasure excursion rather than a serious business enterprise.

THE ADVANTAGES OF HOSPITAL INTERNESHIP.

This is a subject to which but little attention has been given by the journals; perhaps it is because the editors think that the average medical student has neither the time nor the inclination to read anything of a medical nature outside of the prescribed limits. The average student does not read the journals to any extent, but on the other hand, does he try for a hospital position? It is the exceptional man that looks far into the future, who sees the rapid strides of ex-hospital men in the profession, that can make the necessary sacrifice of time and money to obtain the desired end.

A few years ago, the general hospital of one of our largest western cities, drawing its clientelage from a population of over a half million people, a radius of a few miles, a city, a center of medical education, graduating between three and four hundred students annually, gave notice in all the medical colleges, that twelve appointments would be made after a competitive examination. Fourteen came up for the examination, for a position of eighteen months standing, the last six of which would be as house physician or house surgeon, in a hospital accommodating 500, numbering always at least 350 in the house, taking all classes of cases. The same condition of affairs prevails in all the large cities, viz., that only a small proportion of graduates receive hospital training.

Why is it the students are so blind to their own interests? Merely because, in many instances, the value of such an education has not been impressed upon them by those whose opinion they respect. It is the professors of the colleges who should place this subject before their students in the strongest possible terms. It is for the welfare of any college that its graduates should do well, and surely a man of experience will take a higher rank in a community than a man without, especially if that experience be aided by common sense. That a college should progress, it must maintain or increase its matriculation, unless endowed. In the attempt to do this, their highest bid for patronage as printed in the annual announcements, recognized alike by college and prospective student, is the number of their professors who have hospital positions and, especially of late, the number and location of their students who have secured hospital appointments. Is not the latter of far greater importance to the student than the former?

Many students become imbued with the idea that they can not afford the time; that they have their own way to make, and that immediately after graduation, they must rush into the country; to these it may be said that instances are being multiplied of men stepping out of a hospital into a lucrative country practice. Their air of confidence in meeting every emergency, the constant application of the methods they have unconsciously absorbed during their hospital life, soon obtains for them suitable recognition. To obviate this difficulty of losing time, some of the colleges that are requiring four years of attendance for graduation, will take the last year in a hospital in lieu of attendance on the lectures and clinics.

As for the small number who can not or will not apply themselves, whose sole object is in "getting through," in order that they may have framed that inaminate piece of sheepskin without which no graduation is complete, and, hanging it up in their office, imagine that they are physicians, nothing whatsoever need be urged.

There are always some to whom the expense is a serious obstacle, who have just enough money to carry them through college and perhaps for a month or two afterward. To those it may be of interest to know that in every large general hospital, while the internes receive no regular salary for their services, yet there are numerous sources of small if uncertain income, at least sufficient to supply their few wants. Coroner's cases, the signing of insurance certificates, assisting in operations, giving of anesthetics, emergency calls to private cases, an occasional private case of their own, all contribute their mite to the interne's slender income.

The practical experience obtained is not to be measured by pecuniary consideration. Frequently the statement is heard that "a year's experience in a large public hospital is worth ten years of private practice;" even this is placing it upon too low a level. A man in private practice is lucky if he sees twenty-five cases of typhoid fever during his first three or four years of practice. In a large hospital, that number of cases at one time, during certain seasons of the year, is no rarity. Surely the study and comparison of these cases would have an impression so profound as never to be completely eradicated. What a knowledge can be obtained of physical diagnosis by the daily examination of from twenty to twenty-five pathologic chests, continued month after month, new cases constantly presenting themselves! Even a large clinic is no comparison; the noise and bustle, the hurry of the examination, the absence of any particular interest in the case, the fact that the cases are frequently not seen for four or five days if ever again; all these tend to make any impression but a fleeting one.

The personal instruction of the visiting staff; men for the most part of the highest reputation in the several specialties with which they may have identified themselves, is a matter of the greatest importance. One does not learn the difference between bronchial and cavernous breathing by intuition or by reading about them in books; it is only when such differences have been pointed out practically by a competent instructor, that any variation is detected at all, and then only frequent trial will finally enable slight differences to be appreciated; but when once gained, the knowledge is never lost. The value of knowing men who rank so high is not without its advantages; very frequently a staff surgeon becomes so accustomed to his house surgeon, that a career is opened for the latter as soon as he leaves the hospital.

Finally, what can be of more value to a student of medicine, after prolonged study of the case during life, than to follow it to the postmortem room, and find his diagnosis confirmed or determine wherein he has erred? How often a case apparently clinically easy of diagnosis, presents conditions undreamed of when the autopsy is made. One comes more and more to believe that the man who never makes a mistake in clinical diagnosis, is the very man who does not make postmortems.

At the last annual meeting of THE AMERICAN MEDICAL ASSOCIATION, President SENN, in his address, said that he hoped to live to see the time, and he thought it would occur within the next twenty-five years, when European students would be coming to the United States for medical education, rather than that young American physicians should go abroad for what they can obtain as well if not better at home. If such an education can be obtained in this country, surely it is in the large hospitals rather than anywhere else.

Of late, hospital experience is beginning to be looked upon as a thing of value. In some of the large colleges, notably Johns Hopkins of Baltimore, men are not graduated without having served some time in their own hospital. In applying for a medical commission in the Army or Navy, the applicant is always requested to send in certificate of hospital service, if any, and due credit is given for the same.

Let us by all means have ex-hospital men in our community. Let the college professors encourage their students to compete for the positions, and having climbed one step of the ladder of fame, they will be encouraged to mount to the summit.

Let us have a Department of Public Health!

YELLOW FEVER IN THE OLDEN TIME.

In a rare pamphlet[1] before us we learn that "New York sustained in sixteen years (from 1791 to 1807) thirteen attacks of yellow fever, causing the death of at least five thousand persons, and each time compelling the flight from their homes and occupation of many thousands of the population. And it is another interesting fact that, since the year 1807, New York has been visited by it but twice, viz., 1819 and 1822, and the latter visitation was on the opposite side of the city, against which no complaints of nuisances could be made; and the commencement of this period of exemption was, moreover, coeval with the enforcement of a law for the filling up of *these* slips and the general improvement of those ancient haunts, in which the opponents of its importation so clearly saw the domestic source of the disease." This begins the statement of the *domestic origin* theory, coupled with a sneer at NOAH WEBSTER in his work on "Pestilence" that during the Revolutionary War our country was not visited by yellow fever which "*he* [italics are not ours] would doubtless attribute to an interposition of Providence, though he does not hold so in express language. He speaks of it simply as a 'striking fact' in the middle of his labored efforts to prove the source of nearly all epidemics to lie in domestic local circumstances in combination with meteoric influences and the appearance of comets. A more rational solution of the circumstance may, we think, be found in the fact that during the war nearly all foreign commerce was suspended." The next point is well put in a sharp sentence, to-wit, "upon the borders of the city in the immediate vicinity of the shipping, while the neighborhoods of filth and nastiness were exempt, particularly 'the Collect' in Center Street."

Then again from this pamphlet we glean that not sooner than 1805 were infected vessels prohibited from coming within 300 yards of the Island of New York after being discharged of their cargoes. The supplementary law of 1806 more explicitly restricts the vessels from the West Indies and the Mississippi, arriving between June and October, to only four days' detention at quarantine, and prohibits intercourse between their crews and the city of New York except under regulations of the Health Officer. These were the days of sailing vessels with their prolonged voyages, dirty holds, cramped berths, huddled crews and damp cargoes. Thus there were now acknowledged to be some other transmitters of pestilence besides the individuals as well as a recognition of the law that the longer the quarantine the greater the danger. Another report of the same [illegible], which the same body [illegible] Aug. 5, 1807 [illegible] of the preceding year [illegible] tion of the New Orleans Sanitary Commission of 1853, that there is a miasmatic origin of the fever, intensified by both a high temperature and a high degree of humidity. Here is introduced the metaphoric "shears of fate," a harmless instrument when either blade is missing. To this our author replies that, if a law, it is certainly inoperative in New York city or any of its environments. His citations are the epidemics inclusive of the one of 1819, in all of which the visitations had their location on the southeastern margin in the vicinity of the wharves of the East River. Besides these instances, Brooklyn in 1809 had lost between thirty and forty lives in a well-defined area of about two hundred yards semi-diameter, the center of which was a vessel from Havana, on board of which the first case occurred. The first American novelist, Brown, many years ago wrote a most interesting chapter on the adventures of his hero in the Philadelphia epidemic of 1799, the same in which Benjamin Rush won imperishable renown.

---

[1] [illegible]

In 1822 the fever shifted its nidus to the western margin of the city, on the Hudson River, the "residence of a population, aristocratic at least in cleanliness and the elegancies of life." At that time *the domestic origin* theorists were forced to yield the field even to the surrender of the graveyard of Trinity Church. The recital of the episodes in the epidemic of 1856 is exceedingly interesting and the name of a pioneer sanitarian, the late Dr. Elisha Harris, is given a merited prominence for the best of work. But as we have hardly room even for scant justice, we must abide with only summaries. We learn that the total number of cases during the summer and autumn of 1856 was 538, more than one-third of whom died of "black vomit." The whole number of cases which occurred within a circle of five miles radius, having its center at the Marine Hospital, counted up to a figure not much below an additional six hundred. After the due crediting of the rigid quarantine laws, much of evil is attributed to the prevalence of winds sweeping along the lines of the pestilence and the function of the tides in floating the débris of ship refuse to the shores with their zig-zag docks and reeking sewers.

Charleston, Norfolk, Baltimore, Philadelphia and Providence have their share of attention as pictures with grewsome details in this gallery of epidemiology, but enough has already been written in proof of Solomon's wisdom that " there is nothing new under the sun." We are also to bear in mind that this pamphlet adheres closely to the subject of preventive sanitation, and has naught to say of the Antilles as the cradle of the disease, or even of the northern portion of the west coast of Africa. Not so, however, of the sailor quarters, always so close to a harbor.

Let us have a Department of Public Health!

THE MONTREAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

There was something peculiarly appropriate in the fact that the British Medical Association should hold its first meeting outside of the British Islands in the jubilee year. The jubilee enthusiasm possibly emphasized the sincerity and fervor of the patriotic emotion everywhere manifest, and as the President of the Association, Dr. Roddick, said, the meeting would be a powerful influence in knitting together even closer the bonds uniting the great colony to the mother country. It was in truth, as he said, "a great immigration scheme." There was a remarkable consensus of circumstances uniting to bring about a noteworthy unity and unselfishness and to render the meeting quite unique. Canada felt honored by the choice of the meeting place; the railroads wanted travelers and shippers; the country desired immigrants and settlers; and the medical profession by its own good will was able to unite all these and other powerful interests to subserve the common aim, to give a heartiness and good will to the welcome, and to carry to a successful conclusion the great labor of entertaining their visitors. The number of members and invited guests was about 1,200, and with their families there were certainly over 2,000 people to be entertained. For a city relatively small, and a country not so rich as our own, it must be confessed that the work was wonderfully well done. The hotels were taxed, but private hospitality made comfort for all. We heard of some who hired one or more entire houses for their guests. Another hint of the spirit that was active, is the fact that Montreal's most honored citizen and benefactor, Lord Strathcona and Mount Royal, returned from Scotland where he was spending the summer to open his house and help entertain the members of the Association. To Drs. Adami, Springle and Benoit, the most hard-worked but most admirable of secretaries, and to Drs. Armstrong and Birket of the Excursion Committee, every visitor was indebted for foresight, energy and zeal that made the meeting the pronounced social success all are agreed it was.

Lord Lister was certainly the most honored guest, and his presence at every meeting seemed almost to partake of a religious reverence. His feeling was kept distinctly human however by the most charming modesty and kindness on the part of our hero of science, and who through all the adulation preserved a simplicity and self-forgetfulness of bearing that endeared him to all.

This is neither the time nor place to say much of the scientific proceedings, much of which we have already laid before our readers. The interest in professional things is suggested by the fact that in several sections the attendance was from one hundred to two hundred, and during one session the number at the surgical section was as high as 350. The address in medicine by Dr. Osler drew a great audience, which of course, was delighted with the distinguished physician's review of "British Medicine in Greater Britain." Another historical address was that on surgery, delivered by Dr. W. Mitchell Banks. The address of the President, Dr. Roddick of Montreal, was a masterly résumé concerning the medical life and resources of Canada.

We heartily congratulate our Canadian confrères upon the perfect success of their meeting. Every such gathering brings nearer and more certain the attainment of the ideals of our guild, and hastens the coming of the day when all men, as now all physicians, shall be conjoined in a common beneficent work for future humanity.

AMERICAN STUDENTS IN GERMANY.

The United States Ambassador, Hon. Andrew D. White, having established himself at Berlin, has had his attention called to certain new regulations affecting American students at the German medical centers. The governments of Prussia and all other German states having universities, have made alterations in the terms admitting the attendance of medical students at the clinics. Under the new regulations a considerable proportion of American medical students will be shut out, and it is reported that a medical board of Berlin and Brandenburg has presented a request that still more restrictive rules be enforced. It is the object of these petitioners to draw the lines so close that students from the smaller American medical colleges will need to pass a preliminary examination before they can secure certain clinical and didactic privileges. A prominent German newspaper that has endorsed the movement has expressed the opinion that even in the United States it is a matter of surprise that so much laxity has been displayed, and for so long a time, regarding the admission of American students to so many advantages without any adequate examination as to the fitness of those persons to the instructions that they seek. It is also stated that Mr. Ambassador White has begun an inquiry into the nature and effects of the new regulations.

CORRESPONDENCE.

LETTER FROM MOSCOW.

The Twelfth International Medical Congress.

Moscow, Aug. 29, 1897.

To the Editor:—Numerically the Congress was a great success. In fact, the vast throng everywhere present detracted largely from the comfort of each individual member. The Reception Committees were unprepared to receive the great horde of physicians that poured into the city by every incoming railway train.

The consequence was that for the first day or two after the Congress opened everything connected with its organization seemed to be in a state of perfect chaos, und many of those arrived late had great difficulty in procuring lodgings.

However, the medical profession of Moscow worked with an untiring zeal for the individual comfort of each member, and during the last days of our stay we were most sumptuously entertained.

For the meetings of the general sessions there was no building in Moscow that would seat more than one-third of all the members. Delegates were given tickets for all three of the sittings and of the ordinary members not one-half ever got inside of the National Theater, where the meetings were held.

Of the ten great men whose names were down to address the general sessions, those of Virchow and Lombroso seemed to elicit the greatest amount of enthusiasm. When they arose to speak such were the demonstrations of applause that it was some minutes before they could be heard.

The latter spoke in very bad French and in spite of the warm acclamations with which his appearance on the platform was received, the doctrines that he enunciated, which when crystalized, meant that the criminal was a sick man and was deserving of a physician and not an executioner, were received with many smiles of incredulty by the vast throng that listened to him.

At all the meetings it must have been a source of embarrassment to those who spoke English, to observe what an attitude of unrest took possession of the audience as soon as they began to speak. Dr. Lauder Brunton of London delivered his address in French, which though not exactly Parisian in style, his subject matter was excellent and he was listened to with rapt attention.

The Russian would naturally say, that as we ignore in the main our own language, and use one that is more widely known to the scientific world we expect outsiders to conform to the same rule. Professor Senn's case was an exception, for his subject was one that the medical world recognizes Americans as authority on, and he delivered it in a manner that commanded the strictest attention even from those who did not understand English.

Professor Murphy's address before the surgical section on the suturing of blood vessels was also listened to with marked attention. Dr. Frank's illustration of his absorbable intestinal coupler elicited a great deal of interest among surgeons, and such men as Kocher and many others honored him by calling on him to give repeated explanations of the workings of his ingenious device.

Among those who spoke at the last meeting of the general session was Professor Leyden on pulmonary tuberculosis and though he was warmly received when he began, he read his address in such a low and monotonous tone of voice that not one in ten of those present could understand distinctly what he said. From such an eminent authority we naturally expect too much and hence I believe his audience was disappointed because he had so little to tell them that the well informed did not already know.

Of the sixteen sections into which the work of the Congress was divided, that of surgery seemed to draw by far the largest audience. The section on internal medicine was just across a hall from that of surgery and the contrast in the number present at these sittings was at all times most marked. When von Bergmann was reading his paper on brain surgery the hall in which he spoke was filled to suffocation, though his address must, on account of its extremely conservative tone, have been a disappointment to the enthusiastic brain surgeon. The number of those present could not have been less than seven hundred and fifty.

At the same time, in the section on internal medicine the subject of diabetes was being discussed by the best men in that section and by actual count there were just ninety present. This illustrates the tendency in medicine to neglect that branch under which must be classified a vast majority of all cases of disease that we are called upon to treat.

The brilliant success that surgeons claim to be constantly achieving in their branch of medicine has blinded the average young physician to the ordinary everyday ailments of humanity and he turns away with disgust from the consideration of any disease that can not be eradicated with the scalpel.

When Bergmann or Kocher mounted the platform to speak they were received with a deafening round of applause such as one is accustomed to hear when a great actor like Irving or a singer like Patti appears before the footlights in a theater.

Across the hall, when a Ziemssen, a Leyden, a Pavy or a Widal rose to speak no such enthusiasm was manifested. Next to the surgical section that of obstetrics and gynecology was the most fully attended.

In the section on internal medicine Professor Thayer of Baltimore read a paper on "Gonorrheal Endocarditis," which was well received. He illustrated his paper by the clinical history of several cases and mounted specimens of blood, where the symptoms were of an obscure septic type, but which a postmortem showed to be due to gonorrheal infection, producing an endocarditis and other symptoms of general infection. His paper was discussed by several eminent men, who confirmed the facts therein claimed, going even farther in their views in favor of recognizing in a gonorrheal contamination a factor in many obscure cases of infection, and one man claimed that 90 per cent. of joint diseases in the adult, not traumatic in character, were produced by gonorrhea.

Though there were about fifty women physicians in attendance at the Congress, Mme. Antonchevitch's paper entitled "Contribution à la symptomatologie des maladies du pancreas," was the only one I heard read by a woman doctor.

She had a poor command of French and her attempt to deliver it without notes was well nigh a failure. The cardinal idea in her paper was that diseases of the pancreas are extremely difficult to diagnose, that the symptoms of an increased salivation is pretty constantly present, especially when the stomach is empty. This increased secretion apparently from the salivary glands is in fact a redundant secretion from all the alimentary tract as far down as the cardiac opening of the stomach. The secretion, she told us, was often so excessive that an effort at vomiting was necessary to throw it all off.

In my last letter from Edinburgh I spoke of my disappointment in not being able to get a single idea from that renowned city of medical lore on the subject of the treatment of croupous pneumonia. I am glad to inform the readers of the Journal that I have at last found a panacea that will jugulate that terrible disease with almost mathematic certainty. After listening for days to the learned dissertations on the symptomatology and pathology of internal diseases, waiting in vain to catch something that would throw some light on their therapeutic management, I was more than delighted when Dr. Spiklai mounted the stand and read his paper on "Le traitement des maladies croupeuses avec la pilocarpine."

The author claims that all exudations thrown out by mucous surfaces are liquified by this agent and in this condition are readily thrown off or absorbed. Its therapeutic application thus becomes a wide one. It is a sovereign remedy in inflammatory diseases of the genito-urinary tracts in both sexes, and when used early will prevent the later septic developments that follow in the train of many of those diseases. But in croupous affections of the air-passages it acts with a rapidity and efficiency that no other remedy or remedies can equal. In laryngeal croup, tracheotomy and intubation can be dispensed with if pilocarpin is used early and properly. That terrible disease, croupous pneumonia, he cures in from three to four days. The only contraindication in the use of the agent is in severe cases of heart lesion, and even in these, the remedy if used carefully is a perfectly safe one. W. S. Caldwell, M.D.

Antistreptococcic Serum in the Mixed Infection of Tuberculosis.

New York, Sept. 16, 1897.

To the Editor:—Your issue of September 11, contains the very interesting article on "Streptococcic Infection and Marmorek's Serum," by Geo. W. Cox, M.D., of Chicago. In the discussion following the reading of the paper, Dr. Cox states that there is no work on the subject that he knows of, except his communication.

May I take the liberty to call his attention to some experimental and clinical work done in that line by myself over a year and a quarter ago? The results of these experiments I communicated to the Academy of Medicine of New York at its meeting of Jan. 21, 1897, in a paper entitled "The Hygienic, Educational and Symptomatic Treatment of Pulmonary Tuberculosis," which subsequently appeared in the *Medical Record* of February 13.

Three years ago, when I began visiting the European sanatoriums for consumptives for the purpose of studying this phase of phthisio-therapeutics, I noticed that the newly arrived tuberculous patients, who came there with a rather high temperature, after a few days of rest in the open pure air of the sanatorium, experienced an evident general improvement and very marked reduction of temperature, and this without any antipyretic medication whatsoever. I could not account for this sudden reduction of temperature except by the gradual cessation of the mixed infection, or to speak in bacteriologic language, of the association of micro-organisms, especially that of the bacilli of tuberculosis with the streptococci." It is well known that in the higher altitudes the microbes of suppuration, such as the streptococcus and the staphylococcus, are almost totally absent. Thus it seemed rational therapeutics to attack this perhaps the most offending partner in the mixed infection of tuberculosis.

I wrote to Dr. Marmorek and, through his courtesy, I was promptly furnished with the serum directly from the Paris Pasteur Institute. Prof. Biggs, Director of the Bacteriologic Laboratory of the Health Department of New York, very kindly allowed me to test the antistreptococcic action of Marmorek's serum by a series of experiments on animals in the New York laboratory. These having been satisfactory, I began my clinical experiments.

For the benefit of the many readers of the Journal, who may not have read my article in the *Medical Record* of February 13, I may be allowed to summarize rapidly the result of my experiments with consumptives when there were clinical and bacteriologic evidences of mixed infection. The action of the serum was not always uniform. With patients whose temperature rose over 102 degrees F. for several days, I did not obtain any results. When, however, there was a temperature of only 101 degrees F., or a trifle over, with streptococci in the sputum, a first injection of ten cubic centimeters reduced the temperature from one to one and a half degrees. A second of ten cubic centimeters brought it down to nearly normal. A third, fourth, fifth and sixth of five cubic centimeters each, given first every twenty-four hours, then at longer intervals, helped to maintain the normal or nearly normal temperature, and a general better feeling was experienced by the patient. However, I think it will require much more experimentation to fix the real value of the antistreptococcic serum. Its action seems to depend not only upon the make of serum used,[1] but also upon the degree of virulence of the toxins produced by the streptococci in the system. The earlier the injections are made the better seem the results. I should like to encourage its use in pulmonary tuberculosis whenever there is a mixed infection, and when after a short trial absolute rest, fresh air, and the usual antipyretics have failed.

955 Madison Avenue. S. A. Knopf, M.D.

Widal's Typhoid Agglutination Reaction.

St. Paul, Minn., Sept. 19, 1897.

To the Editor:—I have read with a great deal of interest an editorial appearing in your issue of September 18, entitled "Evidence which tends to weaken the value of Widal's Typhoid Agglutination Reaction." I had read the discussion upon this subject which took place at the last meeting of the American Medical Association, and was very much impressed with the fact that where the most careful work has been done there has seemed to be the least divergence of opinion as to the value of this reaction, and the general nature of the reports made as well as the special report made by the Committee seemed to me to leave but little that could cast any doubt upon the specificity of the reaction. The discussion at the recent meeting of the British Medical Society in Montreal, to which I listened with a great deal of interest and instruction, still more firmly established the value of this test. There would really seem to be but two sources of error in the performance of this test at the hands of competent and careful men. One is the fact that the reaction may be absent upon certain days of the disease; this is really very rarely the case and merely indicates the necessity for making more than the one test where a negative result is obtained. The second lies in the fact that occasionally an impure culture, supposed to be typhoid, may give misleading reactions.

There can be no doubt that over refinement in technique has led to some errors of observation, and that on the other hand the acceptance of reports from general hospitals where this test has been performed by several different men leads to error of observation for precisely the same reason that we find similar errors constantly occurring under the same condition where other clinical tests are involved. My own experience based upon the use of the very simplest technique as outlined in my papers published in the *Medical Record* of November 14 and Dec. 5, 1896, has continued to be in all respects favorable to the test which, as I stated at that time, I believe to be worth all the other symptoms of typhoid put together as a means of differential diagnosis. I wrote this letter merely because the editorial question seems to me to unduly magnify certain un important differences of opinion upon the question of technique and thus obscure the more important fact that there is but little actual difference of opinion as to the immense clinical value of the test. Yours truly,

Chas. Lyman Greene, M.D.

Chelidonium Majus for Inoperable Cancer.

Chicago, Sept. 20, 1897.

To the Editor:—In a previous number of the Journal I gave an account of the plan of treating inoperable cancer advocated by Dr. Denicenco of Russia. The method consists of injections of two parts of extract of celandin to one of glycerin. The mixture is thrown into the substance of the tumor and also painted on the surface, and some of it taken by the mouth.

Prof. John V. Shoemaker of Philadelphia publishes in the Journal of September 4 an account of five cases in which he tried Denicenco's plan, without getting any effect whatever on the tumors.

On the other hand I tried it in one case, and found that the tumor sloughed out as if destroyed by a caustic, with a great relief of the patient from pain and distress, corresponding closely to the experience of Dr. Denicenco.

Professor Shoemaker's great eminence in pharmacology and therapy insures the carefulness of his tests, yet the total failure to produce any caustic effect in the tumor shows that something was wrong. Perhaps the sample of chelidonium furnished him was inert, or the mixture may have deteriorated after it was made. Dr. Denicenco says his mixture must be constantly renewed, as it rapidly loses strength if kept.

I knew one instance where a well educated physician used for three weeks a fluid extract instead of a solid one, thus making his mixture far too weak. It produced no effect whatever, *but when he injected a preparation three times stronger* the tumor soon mortified and sloughed out, to the great relief of the patient.

The facts thus far show that a good article, prepared in full strength and not allowed to stand long after the mixture is made, will display its caustic power. It is necessary the herb should be fresh, or at least not very old.

Dr. Denicenco claims that in addition to the local destruction of the primary tumor "the glands become normal." If this is true it is very important, but it seems at first glance at least improbable. I have not had a chance to test the correctness of this statement about the glands, because the latter organs in my case were internal and out of reach.

At present, if there is any value in this plan, it is only for cases which are inoperable, or in which the patient will not consent to operation.

The article of Dr. Denicenco (or Denissenko, as some render the name) first appeared in the *Wratch* of St. Petersburg.

Edmund Andrews, M.D.

65 Randolph Street.

Venesection and Oxygen.

Chicago, Sept. 20, 1897.

To the Editor:—Apropos of the paper by Dr. J. W. Hoff on "Blood-Letting as a Therapeutic Remedy," in the August 28 issue of the Journal, and the letter of Dr. F. Walton Todd in issue of September 18, I am led to relate some of my experiences with blood-letting.

I have perhaps not bled more than a half dozen patients, but have been many times deterred from doing it on account of the popular prejudice against blood-letting.

I have records of two cases which I think especially worthy of report.

The first is that of a man about 30 years old, admitted to Cook County Hospital, Chicago, in August, 1888, during my service as house physician. The patient was suffering from sunstroke. He was unconscious, breathing stertorously, somewhat cyanotic, with pupils dilated and pulse full and bounding. A vein at the elbow flexure was opened and blood allowed to flow until the patient breathed quietly—perhaps twenty to thirty ounces in all. After thirty minutes the patient was conscious and able to talk. Recovery was rapid.

The second case is that of a young man, aged 19. On June 8, 1893, at 9 p. m. I was called and found him suffering great thoracic pain. He had a severe rigor during the afternoon. Temperature 101 F.

June 9—Temperature 101-103, pulse 110; delirious. Pneumonitis left lower lobe.

June 10—Temperature 101, pulse 100. Flighty, but otherwise appears to be doing well.

June 11—Was called in haste at 2:30 a. m. Found the patient gasping for breath; bronchi and throat choked with mucus; respiration 48, pulse 150 and very weak; cyanosis; axillary temperature 105 F.; patient comatose and could not be roused. Spir. ammon. aromat. and spir. frumenti given hypodermically every fifteen to thirty minutes; appeared to cause improvement in all respects. However, at 7 a. m. he relapsed into a worse state than before; respiration 60; lungs, bronchi, trachea and pharynx choked with mucus; pulse 165 per minute, but full; temperature not taken, but apparently very high.

At this juncture I called Dr. A. J. Ochsner, who resided just across the street, in consultation. We quickly decided that the only possible *chance of saving* the patient was by venesection, to which the parents consented. Since it appeared to us that the patient live even minutes we prepared him hastily and opened the median basilic vein at the elbow flexure. Between two and three pints of very dark blood, which coagulated almost immediately, was taken. Before the blood ceased flowing the cyanosis had given place to a bright red color, the pulse was improved and respiration much easier. Digitalis and atropin were given hypodermically. He continued to improve for forty five minutes, then again failed rapidly. Respiration 60, pulse 160 to 175 per minute—at times uncountable.

We gave up then, but I remained to see the end. At 8:30 a. m. he seemed about to take his last breath, but rallied slightly and at 9 o'clock I decided to renew the fight. I sent for oxygen gas and at 10 a. m. gave the first inhalation, having meanwhile continued stimulation and administered a nutrient enema. At first the oxygen was given every ten minutes. At 11 a. m. I left him, still unconscious, but much improved. At 1 p. m. I returned and he greeted me with "Hello, Doctor!" Respiration at this time 60, but not labored; pulse 160; axillary temperature at 3:30 p. m., 105.

June 12—Temperature 101.5 to 103; pulse 132 to 150; respiration 38 to 50. Recovery was slow but complete.

I have not the least doubt that the blood-letting was the primary means of saving this patient's life, though without the oxygen he would probably have died in spite of the bleeding. E. J. MELLISH, M.D.

Blood-letting.

ONEIDA, NEW YORK, Sept. 19, 1897,

To the Editor:—I wish to add my mite and endorse every word in regard to blood-letting by Dr. Todd of San Francisco. In a practice of forty years I have invariably resorted to vene section in all cases of puerperal convulsions and have been fortunate in never losing a patient, and I have had my ratio of cases. Out of nearly two thousand in number, my rule is to bleed at once and repeat if necessary, which has very seldom been the case.

I also bleed in cases of pneumonia and la grippe, especially where the attack is severe, in young and robust patients, and the result has been immediate relief and usually rapid recovery. Not long since I was called in consultation with a young physician: the patient was a robust full blooded man aged 43 years, who had been sick about a week with inflammation of the right lung. He was suffering terribly from difficulty of breathing, pulse full and hard, finger nails and lips cyanosed, and I advised bleeding and took twenty ounces; before bandaging the arm his pulse had decreased from 120 beats to 96. He made a good recovery with no repetition of his bad symptoms. I fully concur with the venerable doctor in all he says in the last section of his valuable article. H. W. CARPENTER, M.D.

Antiseptic Treatment of Typhoid Fever.

WAVERLY, N. Y., Sept. 17, 1897.

To the Editor:—I simply wish, in the interest of a number of your subscribers, to "say *good-bye*" to Dr. ———. It seems a misfortune that you should be obliged or called upon to publish such jargons, but we your readers become disgusted and hope the columns of the JOURNAL, which we all so much admire, may be kept as free as possible from such rubbish. I am not an advocate of "the Woodbridge treatment," or any man's method, but the principle of treatment advocated so bravely by Dr. Woodbridge I have followed with 100 per cent. of recoveries in eighty-three cases (consecutive).

Respectfully, R. S. HARNDEN, M.D.

ANSWER: The Editor is of opinion that the widest latitude should be given gentlemen wishing to comment upon any topic of interest to any considerable number of the profession. It is in fact the "public opinion" department of our JOURNAL, and we venture the assertion that few of those who read the JOURNAL at all fail to read the "correspondence columns." Neither the Trustees nor the Editor assume any responsibility for the individual opinions of the writers, which indeed must stand or fall upon their own merits or demerits, but we are sure that in the main the letters are full of interest, and have a snap and virility which can not be very prominent in the more formal scientific articles.—ED.

Pederasty vs. Prostitution.

NEW YORK, N. Y., Sept. 20, 1897.

To the Editor:—Referring to Dr. Howard's article, "Pederasty vs. Prostitution," in the JOURNAL of May 15, I would state the following facts: "In Japan, where prostitution is licensed, in some of the provinces tea girls and archery gallery girls have assumed the position of unlicensed prostitutes. In the two provinces which have produced the greatest statesmen of that country, notably the statesmen who overthrew the old Tycoon and restored the power of the Mikado, Choishin and Tatsuma, pederasty is wide-spread and licensed prostitution was never permitted. In these provinces and among those who hail from these provinces the homo-sexual vice is shamelessly rampant; it is even theoretically defended with would be scientific arguments. In the Saigo rebellion in 1877 a Minister of the Interior was assassinated because he loved the *bichonen* of another statesman. Bichonen is the name given to the *puer*. The Japanese pederasts contend that the practice is an evidence of mental vigor, as showing a power of resistance to the charms of women. It is but telling the simple truth to say that these men from the provinces addicted to the homo sexual vice represent the ablest minds and the best fighting blood of the empire. The whole modern progress of Japan is due to them.

The harlots of Japan do not represent by any means the "education, wit and wealth" of the country, although in very ancient times all the women of the Taira family, one of the five greatest of Japan, were driven into prostitution by a hostile and victorious clan. It was from this tragic event that the custom arose among the common people to marry prostitutes in order to obtain noble wives.

ALBERT S. ASHMEAD, M.D.

On the Excretion of Urea.

AMSTERDAM, N. Y., Sept. 20, 1897.

To the Editor:—The remarks of Dr. E. P. Stimson in the last number of the JOURNAL upon some statements of mine at the Niagara Falls meeting of the American Association of Obstetricians and Gynecologists, when the subject of eclampsia was under discussion, claim some recognition.

My point was that the elaboration of Haine's modification of Häser's method for the determination of the *total urinary solids* by Dr. Etheridge of Chicago was a very valuable means of detecting renal inadequacy. I placed this in contrast to the Doremus test for *total amount of urea.* The reporter failed to fix the difference, and the figures were therefore senseless.

To those who are unfamiliar with this method of estimating the total urinary solids, references may be found in the Transactions of the Medical Society of New York, for 1896; Gould's Year-Book, for 1897; *Chicago Medical Recorder*, July 1895.

CHARLES STOVER, M.D.

Some Reasons for "Hard Times" Among Physicians.

CHICAGO, Sept. 16, 1897.

To the Editor:--I am very sorry that I can not comply with your letter at the present moment, but will try my best to make it good at my very earliest convenience. From five medical journals, I limited myself to two, including your JOURNAL, so hard is the time on the general practitioner of Chicago. If all the hospitals and dispensaries of Chicago be closed up at once, and only those admitted who possess a certificate of being poor and entitled to free treatment; if no regular physician would accept a case for treatment until the first physician was paid; and if all the medical colleges would, besides their business views, try at the same time to elevate the medical standard, there would be no difficulty for any practicing physician to pay his subscription fees promptly for any number of medical journals. Thinking that these facts need your special consideration, I remain yours very truly, L. S. B.

PUBLIC HEALTH.

Yellow Fever.—Since our record closed, the new cases of yellow fever which seem to be authenticated are as follows: On the 13th, New Orleans, 6 more suspected cases; Ocean Springs, 4 new cases; Barkley, Miss., 1 new case, 4 deaths in the last ten days; population of this town is said to be 25. Two authentic cases were reported at Mobile. The Southern Pacific Railroad has ceased to sell tickets to Texas points. Spain, which is responsible for the yellow fever center in Cuba, and through whose neglect thousands of Americans have lost their lives, and millions of revenue lost, has decided to quarantine all vessels arriving from ports on the Gulf. Secretary Egan of the Illinois State Board of Health went to Cairo from Springfield, and has since remained there. The Chicago Board of Health made an official announcement that refugees could come to Chicago without bills of health, believing it to be perfectly safe.

On the 14th, 3 new cases were reported at Mobile, New Orleans 5, Scranton 1, and 7 at Edwards. A panic existed at Jackson, Miss., and many of the inhabitants started for other points.

On the 15th, New Orleans reported 3 new cases, and there was 1 death at Biloxi.

On the 16th, there was 1 death at New Orleans, and 1 new case at Edwards.

On the 17th, there were 15 new cases reported at Edwards, 7 at Biloxi, 8 at New Orleans, and 2 "suspicious" cases at Cairo, Ill.

On the 18th, there were 6 new cases, 1 death reported at New Orleans, and 11 new cases at Mobile.

On the 19th, the 2 "suspicious" cases at Cairo, Ill., were pronounced yellow fever by Prof. John Guiteras of Philadelphia, who has been temporarily employed as diagnostician by the Marine-Hospital Bureau.

On the 20th one new case was reported at Cairo and eighteen new cases at New Orleans. The Mississippi State Board of Health has quarantined all mails from infected districts of Mississippi. In Illinois the towns south of the Ohio & Mississippi Railroad, 244 miles south of Chicago, have mostly quarantined against Cairo.

On the 21st there were nine new cases reported at New Orleans and one suspected case at St. Louis; this case from St. Louis is from the same source as the cases at Cairo, namely, from the Government dredge-boat which has been engaged in river improvements at East Cairo, Ky.

On the 22d, New Orleans, death of Dr. Lovell reported; 9 new cases and 2 deaths; detention hospital at Oakland established by Board of Health. Ocean Springs, 7 new cases; Biloxi, 2 new cases and 2 deaths; Louisville, 1 case in a refugee from Mobile; Beaumont, Texas, 1 case; New York quarantine, 2 cases.

The Illinois Central Railroad has issued a circular to the ticket agents of the road, and also to agents of connecting lines, to discontinue the sale of tickets to all points in Mississippi and Louisiana, with the exception of New Orleans, and also through all junctions in these States, including New Orleans. The travel south has practically ceased since the outbreak of yellow fever and the passengers now being carried by southern lines are northbound. Railroad officials say that fewer people are leaving the infected districts than last week.

A camp was opened at Fontainebleau, Miss., September 19, under P.-A. Surgeon J. H. White, U. S. M.-H. S., taking 20 people from Biloxi, 10 from Ocean Springs, 12 from Scranton and 13 from different points. In a week he expects to accommodate 800 people, which he believes is the capacity of the camp. Another camp is to be established near Edwards, Miss., by Dr. Geddings, Passed Assistant Surgeon U. S. M.-H. S. These camps have now only local interest, they being established too late to prevent the appearance of the fever in various other points. At Fontainebleau the same system of sending a special train for refugees, which was originated at Camp Perry, Fla., in 1888, has been followed, but as the fever is now both east and west as well as in towns north, the scope of the camp service is limited.

A correction should be made in the report of last week in regard to Galveston. Dr. H. A. West, the Health Officer, states that there has been no case of yellow fever at Galveston.

In New Orleans, a city well within the lines of almost martial rigor, there have been the usual throngs at the Sunday concerts and in the parks; the theaters have been playing to "standing room only." It can not be said that the "wildest rumors prevail," although there are many hopes for the first appearance of frost and an abundant faith in the Board of Health. Dr. Sanarelli's method of investigation as advised by the National government, have been adopted, with some friction perhaps as regards the technique, but it may be said that bacteriologic research is well under way. Aside from the attacks of illness and some fatal issues suffered by the physicians most in contact with the fever stricken, the penal award of the self-sacrificing, there remains an assurance that the visitation will soon be over, without the charge of inhumanity or even of indifference. Edwin Hawley, assistant general traffic manager of the Southern Pacific Railway Company, announces the following: Although assured that public apprehension has materially exaggerated the seriousness of reports of yellow fever in the vicinity of New Orleans, we have determined to protect the interests of our patrons and avoid any delay incident to possible quarantine restrictions during the prevalence of existing conditions, by dispatching direct from New York to Galveston all Morgan Line steamers taking freight for destinations in Texas, New and Old Mexico, Colorado, Utah, Arizona, California, Oregon, China, Japan, Australia and the Sandwich Islands, so that shippers may continue to route their freight via Morgan Line without fear of detention.

A Health Officer's Proclamation Overruled.—An instance of the tendency of certain judicial officers to set aside a sanitary measure *ex post facto* is found in the case Eckhard vs. the City of Buffalo, recently decided by the appellate division of the supreme court of New York. The plaintiff sued to set aside an assessment for upward of $300 that the city had imposed upon her for certain expenses incurred in the abatement of a nuisance existing upon her premises, namely, an old style yard vault. Whatever nuisance there was, says the court, could have been abated by a cleansing of the foul vault, but the Health Commissioner of that city pursued a more radical course and caused the construction of a sewer connected with properly water-flushed closet or closets on the plaintiff's premises and caused the expenses for the same to be charged up against her. This action of the Commissioner has been condemned by the court, which holds that he was authorized to abate the nuisance in any "reasonable manner" but not to go on and make a costly sanitary improvement at the expense of the owner of the premises "for the benefit of her tenants," assuming, as it would appear, that the acts of the Commissioner were not in reality for the benefit of a community rather than for the individual occupants of the pre[illegible] On the part of the city and of the health [illegible]cers it [illegible] that the action taken [illegible]cau of Asiatic cholera at that time at certain seaports of Europe and elsewhere, having more or less close communication with the port of Buffalo, in consequence whereof the health officers of that city had issued a proclamation of great and imminent peril by reason of impending pestilence. Mr. Justice Green, in writing the opinion of the appellate division above mentioned, observes that the proclamation of imminent peril was made in error and that any extraordinary actions for cleansing the city of Buffalo based on that proclamation were also in error. And yet, we may ask, who is to be the judge of an impending danger to the health of a city from imported infections if not the Commissioner of Health? He certainly has to bear the brunt of complaint if he fails in his duty for the protection of the health of his city.

Yellow Fever in Cuba is notably on the increase. All the fatalities so far have been among the Spanish soldiers. Dr. Caminero, stationed at Santiago, reports (September 4) that the sick are taken to the hospitals in public conveyances without protest and that a strange fatuity seems to have seized even the unacclimated. He is to place placards on steamers running between Cuban and American ports warning against these public conveyances.

The New Water Supply of Perth Amboy, N. J.—Water was recently struck at a depth of 175 feet in the artesian well which the city of Perth Amboy has been sinking near the waterworks at Runyon, about seven miles southwest of the town. It was found in fine white sand, below a thick bed of blue clay, and though not as yet quite clear, flows freely from a vertical four-inch pipe, the top of which is sixteen feet above the level of the ground.

Typhoid Fever in Germany.—A special cable dispatch of September 4, to one of our press contemporaries, announces that typhoid fever is almost epidemic at several localities in Germany. The Berlin health authorities are warning the public against the use of milk which has not been boiled.

Diphtheria Epidemic.—According to press dispatches diphtheria is prevalent at Rockford, Ill.

NECROLOGY.

BEDFORD BROWN, M.D., Alexandria, Va., September 13, aged 76 years. During the Civil War he was appointed full surgeon in the Confederate Army by Jefferson Davis; was chief surgeon of the camp of instruction at Weldon, N. C., June to July 1861, when he was assigned chief surgeon of the Southern troops sent from Richmond to enforce General Floyd. Afterward he finished the service as inspector of hospitals and camps. In the medical world he was president of the Virginia Medical Society in 1886; president of the Southern Surgical and Gynecological Association in 1893; member of the Pan-American Medical Congress and of the AMERICAN MEDICAL ASSOCIATION and honorary member of the Medical Society of the District of Columbia.

JOHN H. BEMISS, M.D., New Orleans, September 5, aged 50 years, of yellow fever. Dr. Bemiss was a graduate of the Medical Department of Tulane University of Louisiana; for years president of the Faculty and Professor of the chair of Physical Diagnosis in the New Orleans Polyclinic; visiting physician to the Charity Hospital of New Orleans and member of the Charity Hospital Alumni Association of Louisiana.

JOHN C. BOLLES, M.D., at his home in Montville, Conn., September 11, aged 81 years. He was graduated from the now extinct (Woodstock) Vermont Medical College in 1840, and had held many offices in the gift of his town. A widow, son and daughter are his survivors. He was a type of the old country physician and took pride in being the oldest member of the New London County Medical Society.

CALEB LYON, M.D., Albany, 1871, at his home in Rossville, Staten Island, N. Y., September 11. His father was a former governor of Idaho.——Morison Thomas Hutchinson, M.D., College of Physicians and Surgeons, N. Y., 1889, of Englewood, N. J., September 11, aged 33 years.——John Rendell, M.D., Long Island College Hospital, 1885, of Brooklyn, N. Y., died September 16.——William E. Adams, M.D., Hot Springs, S. D., September 12, murdered on a train at Henderson, Ky.——Burton Z. Aplington, M.D., La Salle, Ill., September 13, aged 41 years, a member of the Illinois State, the North Central Ill., and the La Salle County Medical Societies.——John G. Carroll, M.D., Cleveland, Ohio, September 12, aged 37 years.——Horatio A. Hammond, M.D., Perrysburg, Ohio, September 9, aged 68 years.——E. H. McBride, M.D., Springfield, Mo., September 5.——Leonidas M. Reamy, M.D., Zanesville, Ohio, September 7, aged 61 years.——M. Rooney, M.D., Quincy, Ill., September 12.——Dr. Frithiof Holmgren, Professor of Physiology in the University of Upsala, whose name is associated with tests for color blindness.——Emmerich Poor, M.D., Emeritus Professor of Dermatology in the University of Buda-Pesth, aged 74 years.——Dr. Pirotte, President of the Medical Syndicate of the Western District of Belgium.——T. Debrou, M.D., surgeon to the Hôtel-Dieu of Orleans, author of numerous contributions to surgical literature, aged 83.——Professor Carl Liebmann, head of the Gynecologic Department of the Municipal Hospital of Trieste. Eduard Ritter Von Hofmann, M.D., Professor of Forensic Medicine in the University of Vienna, aged 60 years.——Eugene Vigneron, M.D., lecturer in the Medical School of Marseilles and author of several contributions to surgical literature on diseases of the bladder and urinary passages, aged 35 years.——Theron Tuttle, M.D., College of Physicians and Surgeons, N. Y., 1853, a Brooklyn N. Y. practitioner. September 16, in his 65th year.

SOCIETY NEWS.

The New York State Medical Association will hold its fourteenth annual meeting at the Memorial Hall, 64 Madison Avenue, New York City, October 12, 13 and 14.

Tri-State Medical Society.—The Committee on Arrangements has secured the auditorium of the "Tulane" for the ninth annual meeting, Oct. 12 to 14, 1897, which promises to be the largest gathering in the history of the society. The titles of papers should be sent to the Secretary, Dr. Frank Trester Smith, Chattanooga, Tenn., or to Dr. Willis F. Westmoreland, President, Atlanta, Ga.

Orange Mountain Medical Society Resolutions.—At a regular meeting of this society held Sept. 10, 1897, the following resolutions were adopted relative to the death of Dr. John J. H. Love (*vide* JOURNAL August 7, p. 297, and August 28, p. 453).

Resolved, That in the death of our late friend and associate, Dr. John J. H. Love, this society has sustained a loss which we deeply mourn. A constant attendant upon its meetings, its welfare was ever his earnest care. His voice was invariably raised in behalf of progressive medicine and surgery and his well-weighed opinions were received with that attention and respect which they always merited.

Resolved, That we tender to his family our sincere sympathy in their bereavement, and that a copy of these resolutions be spread upon the minutes of the society and published in the medical press.

WILLIAM PIERSON,
H. B. WHITEHORNE, } Committee.
JAMES S. BROWN,

Mississippi Valley Medical Association.—The program for the twenty-third annual meeting of this Association is now in press, one of the most complete ever presented at any meeting. It contains some one hundred or more titles of papers and on this account the papers will be read in two sections, a medical and surgical. The general sessions and the meetings of the medical section will be held in the Liederkranz Hall, the surgical section in the Scottish Rite Hall next door. Both halls are admirably adapted for the meetings. The medical section will be presided over by the President, Dr. Stuck, and the surgical section by one of the vice presidents. Already all the available space in the exhibit hall has been reserved by some twenty-five firms, and this will be a prominent feature of the meeting. The title of the address on medicine by Dr. Shoemaker, will be "Progress and Problems in Medicine"; the title of Dr. Murphy's address in surgery has not been received. The local committee has provided entertainment in the way of a "smoker" on one evening and a reception at the Louisville Hotel for another evening. The visiting ladies will be entertained by the wives of the members of the profession, and it is hoped that many will come. Trolly rides, luncheons, etc., will be given the ladies. The members of the Association will be welcomed on behalf of the city and State by Governor W. O. Bradley and on behalf of the profession by Dr. William Bailey. The Pendennis Club has very courteously extended the members the privileges of the Club, which is very near the place of meeting.

The Wayne County Medical Society held a meeting September 9 at Detroit, and Dr. A. N. Collins read a paper entitled "Report of a Case of Exophthalmic Goiter." The history of the case read presented many points of interest, some of which would go to support the theory that in the medulla oblongata is to be found the seat of the disease. The report was about as follows:

X. Y., male, age 45, occupation stationary engineer; family history negative, had never employed a physician for himself until present trouble began. The first symptoms which presented, without any apparent cause, were nervousness, tachycardia and enlargement of the thyroid gland with some rise of temperature. Thyroiditis was diagnosed, the patient put to bed, ice applied to the neck, and heart remedies given. In the course of a short time some improvement began and the patient was allowed to resume work, with the result, however, that in a few days the rapid heart action returned, the goiter increased in size and the third classic symptom, exophthalmos, made its appearance. From that time on treatment was without avail; strophanthus, digitalis, trional, cactus grandiflora, atropin, galvanism, were all faithfully tried with only an exaggeration of the symptoms. Glycosuria and signs of bulbar paralysis occurred, pointing to a lesion of the medulla. The patient finally succumbed about eight weeks after coming under the author's notice.

The Doctor theorized concerning the antithesis of exophthalmic goiter and myxedema, stating that in the latter there is deficiency of thyroid secretion producing the pathologic increase of certain of the soft tissues of the body, while the former, owing to a hypersecretion of the thyroid gland, produces a progressive wasting and emaciation. He thought the disease easily divisible into two types, benign and malignant. In the former the classic symptoms supervene after some simple shock to the nervous system which does not produce any organic change, and is therefore curable. The malignant type is most likely due to some organic lesion of one or more of the nerve centers, possibly the medulla.

BOOK NOTICES.

The Liver of Dyspeptics; and particularly the Cirrhosis Produced by Auto-Intoxication of Gastro-Intestinal Origin. By Dr. Emile Boix; translated from the latest French edition by Paul Richard Brown, M.D., Major and Surgeon, U. S. Army. G. P. Putnam and Sons, New York and London, 1896.

In this work Dr. Boix seeks to establish the fact that in addition to alcohol as a cause of hepatic cirrhosis, and independent of some other hitherto recognized causes, there is auto-intoxication present, and this auto-intoxication is of gastro intestinal origin. The author has, we think, demonstrated that there is a peculiar form of hypertrophic cirrhosis which is caused by the passage through the liver of toxic substances produced in a diseased alimentary canal, and he uses the term "dyspeptic liver" just as the term "alcoholic liver" is used to designate the effect of another form of cirrhosis.

The first part includes three chapters, one treating of auto-intoxication of gastro-intestinal origin; the second enumerating products of fermentation capable of exercising a pathogenic action; third, conditions which favor abnormal fermentations and the production of these poisons. In the second part, after some preliminary considerations in regard to the antitoxic role of the liver, the clinical history of the dyspeptic liver with its two forms, congested and cirrhous, are given. Finally, the pathologic anatomy of dyspeptic cirrhosis, which is here placed among the scleroses of the liver. The third part is devoted to the relation of the different experiments upon which the author has based his work. The plates are beautiful, and the translation is well done. This book will be a desirable addition to the physician's library.

The Johns Hopkins Hospital Reports. Volume VI. Baltimore, The Johns Hopkins Press, 1897. Pages 409.

This volume contains seventy-nine illustrations and various reports, as follows: Report in Neurology, by Henry J. Berkley M.D., consisting of studies on the lesions produced by the action of certain poisons on the cortical nerve cells, to which is added a chapter on the intra-cerebal nerve fiber terminal apparatus and modes of transmission of nervous impulses, and asthenic bulbar paralysis. Report in Pathology, by Cullen, Booker and Flexner, under the following heads: Fatal Puerperal Sepsis due to Introduction of an Elm Tent, by Thomas S. Cullen; Pregnancy in a Rudimentary Uterine Horn, Rupture, Death; Probable Migration of Ovum and Spermatozoa, by Thomas S. Cullen and G. L. Wilkins; Adeno-myoma Uteri, Diffusum Benignum, by Thomas S. Cullen; A Bacteriologic and Anatomic Study of the Summer Diarrheas of Infants, by William D. Booker; The Pathology of Toxalbumin Intoxication, by Simon Flexner.

The plates in this volume are heliotypes executed in the highest style of art and some Leipzig chromo-lithographs, and also a few by Hoen & Co., in Baltimore.

The Diseases of Women; A Hand-Book for Students and Practitioners. By J. Bland Sutton, F.R.C.S., England, and Arthur E. Giles, M.D., B. Sc., London, F.R.C.S., Edinburgh; with 115 illustrations. Philadelphia: W. B. Saunders. London: Rebman Publishing Co. 1897. Price, $2.50 net.

This excellent volume contains the essentials of gynecology in a handy compact form for the use of students. It is well illustrated, and the text has been carefully prepared. Careful examination of the book shows that nothing essential has been omitted, and its teachings are those recommended by the leading authorities of the day.

Principles of Medicine; Designed for Use as a Text-book in Medical Colleges and for Consideration by Practitioners Generally. By Charles S. Mack, M.D. Chicago: The W. T. Keener Co., 1897. Pages 133.

"The object of this little book," says the author, "is to show just what is the cure sought in any given practice of homeopathy—to show that that cure can not be intelligently attempted excepting under the guidance of *similia similibus curantur* as law, and to show that one may consistently accept homeopathy and at the same time accept whatever else is good in medicine."

In this nineteenth century, when sectarianism is dying out everywhere, it is refreshing to see this attempt on the part of a Hahnemannic practitioner to revive the dying embers of the homeopathic flame. However, the book is not wholly without some grains of common sense.

The author says on page 85: "I do not teach potency. I advise students to go slow if they tend to believe in high potencies." Again: "I do not use the Organon as a text-book. I think one can better teach homeopathy without the Organon as a text-book than with it." Once more: "It is perfectly well known that a very large majority of us homeopathists do not repudiate practices which we think useful, although they are not instances of homeopathy." In other words, according to our author, whatever he is satisfied cures the patient is of Asiatic cholera at that time at certain seaports of Europe and elsewhere, having more or less close communication with the port of Buffalo, in consequence whereof the health officers of that city had issued a proclamation of great and imminent peril by reason of impending pestilence. Mr. Justice Green, in writing the opinion of the appellate division above mentioned, observes that the proclamation of imminent peril was made in error and that any extraordinary actions for cleansing the city of Buffalo based on that proclamation were also in error. And yet, we may ask, who is to be the judge of an impending danger to the health of a city from imported infections if not the Commissioner of Health? He certainly has to bear the brunt of complaint if he fails in his duty for the protection of the health of his city.

Yellow Fever in Cuba is notably on the increase. All the fatalities so far have been among the Spanish soldiers. BOOK NOTICES.

The Liver of Dyspeptics; and particularly the Cirrhosis Produced by Auto-Intoxication of Gastro-Intestinal Origin. By Dr. Emile Boix; translated from the latest French edition by Paul Richard Brown, M.D., Major and Surgeon, U. S. Army. G. P. Putnam and Sons, New York and London, 1896.

In this work Dr. Boix seeks to establish the fact that in addition to alcohol as a cause of hepatic cirrhosis, and independent of some other hitherto recognized causes, there is auto-intoxication present, and this auto-intoxication is of gastro-intestinal origin. The author has, we think, demonstrated that there is a peculiar form of hypertrophic cirrhosis which is caused by the passage through the liver of toxic substances produced in a diseased alimentary canal, and he uses the term "dyspeptic liver" just as the term "alcoholic liver" is used to designate the effect of another form of cirrhosis.

The first part includes three chapters, one treating of auto-intoxication of gastro-intestinal origin; the second enumerating products of fermentation capable of exercising a pathogenic action; third, conditions which favor abnormal fermentations and the production of these poisons. In the second part, after some preliminary considerations in regard to the antitoxic role of the liver, the clinical history of the dyspeptic liver with its two forms, congested and cirrhous, are given. Finally, the pathologic anatomy of dyspeptic cirrhosis, which is here placed among the scleroses of the liver. The third part is devoted to the relation of the different experiments upon which the author has based his work. The plates are beautiful, and the translation is well done. This book will be a desirable addition to the physician's library.

The Johns Hopkins Hospital Reports. Volume VI. Baltimore, The Johns Hopkins Press, 1897. Pages 409.

This volume contains seventy-nine illustrations and various reports, as follows: Report in Neurology, by Henry J. Berkley M.D., consisting of studies on the lesions produced by the action of certain poisons on the cortical nerve cells, to which is added a chapter on the intra-cerebal nerve fiber terminal apparatus and modes of transmission of nervous impulses, and asthenic bulbar paralysis. Report in Pathology, by Cullen, Booker and Flexner, under the following heads: Fatal Puerperal Sepsis due to Introduction of an Elm Tent, by Thomas S. Cullen; Pregnancy in a Rudimentary Uterine Horn, Rupture, Death; Probable Migration of Ovum and Spermatozoa, by Thomas S. Cullen and G. L. Wilkins; Adeno-myoma Uteri, Diffusum Benignum, by Thomas S. Cullen; A Bacteriologic and Anatomic Study of the Summer Diarrheas of Infants, by William D. Booker; The Pathology of Toxalbumin Intoxication, by Simon Flexner.

The plates in this volume are heliotypes executed in the highest style of art and some Leipzig chromo-lithographs, and also a few by Hoen & Co., in Baltimore.

The Diseases of Women; A Hand-Book for Students and Practitioners. By J. Bland Sutton, F.R.C.S., England, and Arthur E. Giles, M.D., B. Sc., London, F.R.C.S., Edinburgh; with 115 illustrations. Philadelphia: W. B. Saunders. London: Rebman Publishing Co. 1897. Price, $2.50 net.

This excellent volume contains the essentials of gynecology in a handy compact form for the use of students. It is well illustrated, and the text has been carefully prepared. Careful examination of the book shows that nothing essential has been omitted, and its teachings are those recommended by the leading authorities of the day.

Principles of Medicine; Designed for Use as a Text-book in Medical Colleges and for Consideration by Practitioners Generally. By Charles S. Mack, M.D. Chicago: The W. T. Keener Co., 1897. Pages 133.

"The object of this little book," says the author, "is to show just what is the cure sought in any given practice of homeopathy—to show that that cure can not be intelligently attempted excepting under the guidance of *similia similibus curantur* as law, and to show that one may consistently accept homeopathy and at the same time accept whatever else is good in medicine."

In this nineteenth century, when sectarianism is dying out everywhere, it is refreshing to see this attempt on the part of a Hahnemannic practitioner to revive the dying embers of the homeopathic flame. However, the book is not wholly without some grains of common sense.

The author says on page 85: "I do not teach potency. I advise students to go slow if they tend to believe in high potencies." Again: "I do not use the Organon as a text-book. I think one can better teach homeopathy without the Organon as a text-book than with it." Once more: "It is perfectly well known that a very large majority of us homeopathists do not repudiate practices which we think useful, although they are not instances of homeopathy." In other words, according to our author, whatever he is satisfied cures the patient is homeopathy, and with such broad claims as this, we may be sure that the homeopaths are better practitioners than they were in former days.

Text-Book on Diseases of Women. By CHARLES P. PENROSE, M.D., Ph.D. Illustrated. Philadelphia: W. B. Saunders, 1897. Price $3.50 net. Pages 529.

There is no lack of text-books on gynecology, but we suppose every gynecologist to be in fashion must write one. If all, however, were able to write from so extended an experience and use such charming English as Dr. Penrose, it would be the better for the profession, and there would be more excuse for writing. The march of science and the progress of pathologic discovery make it necessary from time to time that new text-books shall be prepared for the use of colleges, and the one under consideration is worthy of great praise. The illustrations are very fine and the typography all that could be desired. We venture to predict that this work will take rank among the most popular text-books on the subject, as it deserves to, and that a second edition will be speedily called for. We would suggest, in the second edition, that the author recognize the metric system of dosage to make it conform to the modern pharmacopeia.

American Academy of Railway Surgeons. Report of the Proceedings of the Third Annual Meeting, held in Chicago Sept. 23-25, 1896. Edited by R. HARVEY REED and published by the AMERICAN MEDICAL ASSOCIATION PRESS. 1897. Pp. 282.

In these days of specialism desperate efforts are made to establish a just claim of an alleged specialty to be considered such, and the publication of a volume such as this of the American Academy of Railway Surgeons is a case directly in point, and it must be admitted after an examination of the book that the railway surgeons have fairly made out their case. Albeit there is a tendency to look at everything through the spectacles of the corporation rather than those of the unfortunate patients. This volume is a very handsome one, well edited and is enriched by numerous photographs of members of the Academy, and the papers, which have been heretofore printed in the JOURNAL, are carefully illustrated. Dr. Reed's assertion that "the editor feels that his ambition is being gratified in so much that each succeeding volume of the transactions has excelled its predecessor," is well sustained. The editor says in his preface: "With each year's experience it has been demonstrated that the higher the order of railway surgery the greater the protection of the employe, the passenger and the patient." This is undoubtedly true. The editor might put it in another way, namely, the greater the knowledge of the railway surgeons' association and of the individual members the more efficient they become—a truism which we suppose no one would care to dispute.

The volume will be found very useful not only to railway surgeons but to general surgeons as well, who are not only compelled to treat many of the cases herein discussed, but are usually on the other side of the cases in the witness box when they come up for adjudication in the courts. The volume, which is worthy of all praise, is a very welcome addition to the library of every progressive surgeon.

Atlas and Essentials of Bacteriology. By PROF. K. B. LEHMANN and DR. RUDOLPH NEUMANN. With 63 chromo-lithographic plates, comprising 558 figures and numerous engravings. New York: Wm. Wood & Co. 1897.

This work consists of atlases with explanations of the same, and will be found very valuable for purposes of comparison to all students and laboratory workers. The latter part of the work is devoted to morphology, vital conditions and effects of bacteria and observations on nutrient media. There is a technical appendix which gives recommendations and brief descriptions. This contains the most necessary data, those which in the experience of the authors have proved most practical. The preparation of sections and methods of handling cultures are thoroughly explained. There is no work that we know of to take the place of this for use in the laboratory. The plates are chromo-lithographs, and have been executed by one of the most celebrated firms in Bavaria. As they were prepared under the directions of the authors, their accuracy is unquestioned.

MISCELLANY.

Personal.—Augustus P. Clarke, M.D., of Cambridge, Mass., was chosen an honorary president of the Section of Obstetrics and Gynecology of the Twelfth International Medical Congress, held in Moscow, Russia, August 19 to 26, 1897.

A Mycologic Club.—An interesting society, at New York City, has been formed for the purpose of arousing a wider appreciation of the value of a cheap and abundant supply of edible mushrooms. The members hold monthly meetings, which are devoted to the study of mycologic specimens; and it is expected to interest the public by holding open meetings. The present membership numbers thirty.

Legal Definition of "Maiden."—From an examination of the definitions of the foremost lexicographers, the supreme court of Vermont comes to the conclusion, in the case of State v. Shedrick, that the common ordinary meaning of the word "maiden" is a young unmarried woman or female, not necessarily a virgin, and this meaning of the word it adopts in construing an indictment of a man for adultery with a "maiden."

Large Medical Estates.—The London letter of the *American Practitioner and News*, says that among the wills of the medical profession proved during 1896, that of Dr. Patrick Fraser, £420,000, dwarfed all others into insignificance. Then came Sir John Erichsen with less than £90,000 and Sir George Humphrey with a trifle under £80,000. It is said that, like Sir William Gull's estate of £342,000, Dr. Patrick Fraser's fortune was chiefly built up by judicious investment.

A Source of Sulphuretted Hydrogen.—According to the *Microscopical Journal*, the explanation of the phenomenon why fish could not live in the Black Sea at a depth greater than 200 fathoms, was due to the countless number of microbes that make their home in the ooze at the bottom. Away back in 1850 scientists knew that the superabundance of sulphuretted hydrogen was the destroying agent, but not until recently did the microbiologists point out the true origin of the destroying agent. This microbe, named bacillus hydrosulfuricus ponticus, decomposes mineral sulphates and has the virtual powers of a noun of multitude.

The St. Petersburg School of Medicine for Women.—The Director of the St. Petersburg School of Medicine for Women (Professor Anrep) recently stated that 160 students have entered for the first course. By a recent ukase women who are not Christians will be admitted. The number of such students, however, must never exceed 5 per cent. of the total, which is the actual proportion at present. More than a hundred applicants have had to be refused admission on the score of want of room. The first course of study includes anatomy, histology, physiology and the preliminary subjects, besides dogmatic theology, which is compulsory for the first half year.—*British Medical Journal*, September 4.

Foreign University Intelligence.—Jena: Dr. Richard Neumeister, Extraordinary Professor of Physiologic Chemistry, has retired.—Königsberg: Dr. E. von Esmarch, Extraordinary Professor of Hygiene and Bacteriology, has been appointed to the chair of Hygiene. The chair of Gynecology is still vacant as it has been declined by Professor Bumm of Basel.—Marburg: Dr. A. Schirmer of Basel has been appointed to the newly established professorship of odontology. Dr. A. Dubler, Extraordinary Professor of Pathologic Anatomy and Bacteriology, has been obliged, owing to the weak state of his health, to retire.—Vienna: Dr. Hugo Wintersteiner has been recognized as privat docent in ophthalmology.—*Lancet*, September 4.

Respiration Due to Hematosis and Osmosis of Dissolved Gases.—Vergara Lope and Herrera of Mexico, who have attracted attention by their studies of the effect of altitudes on the circulation, etc., announce that moisture is the essential condition to respiration. The mucous membrane is always moist, and the oxygen in the air is dissolved by contact with this moist surface and is absorbed by gaseous endosmosis. This is the entire process in fishes, but in warm-blooded animals and man there is, besides this, a chemic endosmosis: the oxygen is attracted through the tissues by chemic affinity with the hemoglobin. The absorption of oxygen is independent of the exhalation of carbon dioxid, which is similarly dissolved and exhaled by the same effect of moisture and gaseous osmosis, but it requires movement of the dissolving fluid. The process is merely dissolving in the lower animals; dissolving plus combination in the higher animals. This process of respiration is identical in a decaying body, a river, a living body.—*Revista de Anat. Pat. y Clin.*, June.

Bacteria in Ink.—It sometimes happens that a trifling scratch or puncture made with a pen gives rise to dangerous septicemia. The chemical constituents of the ink which is introduced by the pen into the wound are not capable of producing septicemia, but microscopic examination proves that the ill effects are due to the liability of ink to contain pathogenic bacteria. Dr. Marpmann of Leipzig has recently published the results of the microscopic examination of sixty-seven samples of ink used in schools. Most of thém were made with gallnuts and contained saprophytes, bacteria and micrococci. Nigrosin ink, taken from a freshly opened bottle, was found to contain both saprophytes and bacteria. Red and blue inks also yielded numerous bacteria. In two instances Dr. Marpmann succeeded in cultivating from nigrosin ink a bacillus which proved fatal to mice within four days. This ink had stood in an open bottle for three months, and the inference to be drawn from the inquiry is that ink used in schools should always be kept covered when not in use.—*Lancet.*

Color Photography.—Photography in natural colors appears at last to have been achieved, and if this be so an advance equal in importance to that brought about by the X-rays has been made. The process is at present a secret one and will doubtless remain so until the necessary steps are taken to protect the inventor. From a purely scientific point of view it is regrettable that such a course has been decided upon, but in these utilitarian days there are few, we imagine, who would be justified in finding fault with the inventor on this account. The process, which has been demonstrated in the laboratory of King's College in the presence of such men as Prof. Millar Thomson, Mr. Herbert Jackson, Captain Abney and Sir Henry Trueman Wood, consists in taking a negative in the ordinary way on a gelatin plate which has been treated with a solution of certain salts, the nature of which is a secret. The negative is developed in the ordinary way and differs in appearance but little from an ordinary negative. The positive produced from this looks like an ordinary transparency with no sign of color. It is then immersed after the manner of intensifying an ordinary negative by mercury solution, in three colored solutions, blue, green and red, when the tones appear to possess a selecting action, selecting just that color and tint which characterize the parts of the original subject. The results, it is stated, are exceedingly beautiful and artistic and surpass the achievements of hand work.—*Lancet.*

Medical College for Native Women in India.—The North India School of Medicine for Christian Women was started in Ludhiana a little over two years ago. Dr. Edith Brown, the principal, is supported by a small but well qualified English staff. A very earnest appeal on behalf of its operations comes to us from Miss Harriet Crawfurd of Meerut. The skill of women doctors in India, she says, is now so fully recognized that the demand is far beyond the supply. Crowds daily visit the hospitals and dispensaries, where the energies of the staff are fully taxed to cope with the work. Then there are multitudes of women in secluded homes who would welcome a lady doctor and gladly pay for help and advice. In this school at Ludhiana the great desire is to train up native women for the work. No religious instruction is given in the government hospitals, and native Christian girls can better be trained in such places as the North India School, which is quite unsectarian.

Symptomatology of Alcoholism.—A careful study of 400 alcoholics has been made during the last fifteen years at Zurich under Forel's supervision, and again the fact of heredity is emphasized; 43 per cent. of the cases had one or both parents alcoholic, and 40 per cent. had nervous or mental antecedents. Fifteen per cent. of the patients were wholesale or retail dealers in liquors. One hundred and thirty-two out of 346 had become alcoholics without drinking liquors, consuming merely beer, wine or ciders. Alcoholism is most frequent between 20 and 60 (93.5 per cent.). Below that age a case is almost sure to be direct heredity. All the cases showed various physical, mental and moral alterations: degeneration of the heart, arterio-sclerosis, affections of the stomach, tremor, ataxia, pupillary troubles, general denutrition, etc. One-fifth were sexual perverts (hyperesthesia, precocious debauchery, inversion, exhibitionism). Fourteen per cent. were epileptics; in six cases the attacks followed alcoholic excess and disappeared entirely when the patients refrained from alcohol. The point is noted that the griefs to which patients frequently refer their alcoholic excesses are often found to have followed them.—*Ann. de la Soc. Méd. Chir. de Liége*, June.

A Little Physiology is a Dangerous Thing.—Vegetarians have hitherto been regarded as the most self-denying of mortals in the matter of food, but a new prophet has arisen and it behooves them to look to their laurels. The immortal Hiya, or She-who-must be-obeyed, enunciated the aphorism: "Fruit is the only true food for man," and now we have Miss Loie Fuller, the *danseuse*, declaring, through the medium of an illustrated paper, that the sole way to prolong life like the patriarchs of old to a hundred years or more is by becoming strictly frugivorous. Skirt dancing is scarcely an occupation calculated to develop or foster asceticism in any form, but the fact remains that one of the most talented exponents of the pastime has made her appearance as an uncompromising denouncer, not only of animal food in general, but even of edibles containing starch. "We are governed by custom, whereas we ought to be led by the promptings of nature," cries this fervent disciple of Plato in her exordium, and then with some inconsistency proceeds to the solemn warning: "We are slaves to the palate, let us strive to become its master." That Miss Fuller's physiology is as novel as it is ingenious the following example will show: "The sugar in the sweet fruits serves the same end as starch in other things. Starchy substances must change first into dextrin and then into glucose, ere they reach the stage dates and figs have already attained. The ripening process has brought them to the condition whereto starch is reduced in the human body. On this development nerve force is exhausted, and the tissues are gradually weakened, all which may be avoided by replacing starchy foods with naturally sweetened ones." In fact, the entire article is brimming over with learning, but alas! that we should have to say so, it is the kind of learning against which Pope warns us. London *Lancet.*

Louisville.

YELLOW FEVER.—This State, under the direction of the State Board of Health, has inaugurated a very thorough system of inspection of all in-coming trains from the infected district south. An invitation has been extended the refugees from the South, but the hundreds who come to Kentucky must show a clean bill of health before they are allowed to stop at any point. Inspectors of the State Board personally see every passenger on southern trains soon after the State line is crossed, and if any suspicious case is found the orders are to detain it and all the passengers in the car. The baggage on all these trains is opened and disinfected en route with formaldehyde gas, each trunk or piece of baggage being labeled "disinfected." If the coaches' final destination is at any point in Kentucky, it is fumigated with formaldehyde before it is used again; if it is a through coach it is allowed to proceed. Every passenger arriving in Louisville is sworn to report every morning for a week to the health officer, and if he does not an officer of the Board looks him up at the address given the various inspectors. Louisville has just experienced an unprecedented "spell" of hot weather and a long drouth, both being terminated by a heavy rain and a lower temperature, which of itself is ample to prevent any rooting of yellow fever in the city, should a case elude the vigilance of the inspectors.

Texas Fever.—For some weeks cattle affected with Texas fever have been shipped into Illinois from Kentucky points, and this called forth a protest from that State's officials. Investigation showed that cattle infested with "ticks" have for some time been sent from Tennessee and shipped through Kentucky to Illinois points. Governor Bradley at once called the attention of Tennessee's chief executive to this and a quarantine will be established at once against Tennessee cattle if the practice is not stopped.

Medico-Chirurgical Society.—The first meeting of this Society after the summer vacation was held at the Pendennis Club, the guest of Dr. L. S. McMurtry, with a full attendance. Some interesting clinical cases were reported. Dr. J. M. Williams exhibited the patient from whom the rectum had been resected, some five months ago, for epithelioma, the patient being in excellent condition. Dr. A. M. Cartledge exhibited a specimen of large polycystic tumor, and Dr. W. O. Roberts, a gallstone of peculiar formation, much like a piece of coral.

Washington.

Health of the District.—The report of Health Officer Woodward for the week ended September 11 shows the number of deaths in the District to have been 126. Of this number 67 were white and 59 colored. Among the principal causes of death were, nervous diseases 20; circulatory 9; intestinal 16; respiratory 16. There was one fatal case of diphtheria; 4 of typhoid fever; 3 of whooping cough.

Pay of Police Surgeons.—The police surgeons have joined in a petition to the commissioners, urging an increase in their gross estimate for the pay of the police surgeons of the District. Under the present rate the surgeons receive a monthly salary of $45. Last year the calls and office consultations amounted to over fifteen thousand, and under the present salary they were paid for each consultation less than nine cents. Probably no city in the world has a more efficient corps of police surgeons, and the commissioners should recognize their worth and give them a compensation commensurate with their professional labors.

Physician to the Poor.—Dr. E. F. Cummiskey has been appointed physician to the poor during the absence of Dr. Edward E. Richardson.

To Study in Europe.—Dr. John A. Koch, one of the house staff at the Garfield Hospital, has resigned to go to Vienna, where he will take up a special line of study.

Societies.

The following meetings are noted:

Alabama.—Madison County Society of Huntsville, September 6.

Iowa.—Missouri Valley Medical Society at Council Bluffs, September 16.

Kansas.—The Topeka Academy of Medicine, September 13.

Kentucky.—The physicians of Louisville recently organized the Weaver Club with 200 members.

Michigan.—Calhoun County Medical Society at Marshall, September 14.

Minnesota.—St. Louis County Medical Society at Duluth, September 9.

New Hampshire.—Somerset and Berwich Medical Association at Somersworth, September 9.

Ohio.—Muskingum County Medical Society at Zanesville, September 9; North Central Ohio Medical Society at Marion, September 24; Stark County Academy of Medicine at Canton, September 7.

Pennsylvania.—Erie County Medical Society at Sommerheim, September 7; McKeon County Medical Association at Bradford, September 10.

CHANGE OF ADDRESS.

Alabama Medical and Surgical Age, from Anniston to 2107 Third Avenue, Birmingham, Ala.; Anderton, W. B., from East Quoque to 34 W. 47th Street, New York, N. Y.

Beatty, J. T., from Highlands to 2336 Boulevard, Denver, Col.; Blankner, F., from St. Louis, Mo., to Calumet, Mich.; Braselton, B. F., from Gainesville to Pendergrass, Ga.

Campbell, R. A., from 267 Cedar Avenue, to Room 1, Syndicate Block, Minneapolis, Minn.; Cooke, Henry G., from Holmdel to 7 Livingston Avenue, New Brunswick, N. J.

Eaton, F. B., from Y. M. C. A. Building to Porter Building, San Jose, Cal.; Edwards, F. H., from 315 to 320 State Street, Chicago, Ill.

Hopkinson, B. Merrill, from 1825 N. Calvert Street to 1325 Park Avenue, Baltimore, Md.

Kirpatrick, M., from Boulder, Colo., to 116 Jackson Place, Baltimore, Md.; Knopf, S. A., from 319 W. 58 Street to 935 Madison Avenue (near 75th Street), New York, N. Y.

Luebbers, A. from 2407 N. Jefferson Avenue to 2001 N. Market Street, St. Louis, Mo.

Makuen, G. H., from Cresson Springs, to 1419 Walnut Street, Philadelphia, Pa.; Muir, Jos., from 128 W. 45th Street to 254 W. 34th Street, New York, N. Y.; McDaniel, E. B., from Cove to Baker City, Ore.; McGahan, C. F., from Bethlehem, N. H., to Aiken, S. C.

Orth, D. A., from Milwaukee, Wis., to 756 W. Chicago Avenue, Chicago.

Pipes, Jno. R., from Crestline to Mansfield, Ohio.

Sherman, W. P., from Chicago to cor. River Street and Downer Place, Aurora, Ill.; Stathers, W. E., from Wheeling to Weston, W. Va.

Tessler, Marcus, from Kendrick to Baltimore Block, St. Paul, Minn.

Waiss, G. C., from 342 W Harrison Street to 1022 W. 21st Street, Chicago; Welch, J. P., from Holbrook to Glendale, Ariz.

LETTERS RECEIVED.

THE PUBLIC SERVICES.

Army Changes. Official List of Changes in the Stations and duties of officers serving in the Medical Department, U. S. Army, from September 11 to 17, 1897.

Capt. Junius L. Powell, Asst. Surgeon (Ft. Riley, Kan.), ordered to report to the president of the examining board, Denver, Colo., for examination as to his fitness for promotion.

First Lieut. James M. Kennedy, Asst. Surgeon, will be relieved from duty at Ft. Missoula, Mont., and is ordered to Ft. Washington, Md., for duty at that post.

Capt. Ashton B. Heyl, Asst Surgeon (Ft. Riley, Kan.), is granted leave of absence for one month.

Capt. Henry A. Shaw, Asst. Surgeon, leave of absence granted is extended one month.

Lieut.-Col. J. V. D. Middleton, Deputy Surgeon General (chief surgeon, Dept. of California), is granted leave of absence for one month, to take effect on or about the 20th inst., with permission to apply for an extension of one month.

Capt. Ogden Rafferty, Asst. Surgeon, leave of absence granted is extended one month.

A board of officers to consist of Major [illegible] Joseph K. Corson Surgeon: Major [illegible] appointed to meet at Denver, Colo., [illegible] 10 o'clock A.M., for the examination of such officers of the [illegible] Department as may be ordered before it, to determine their fitness for promotion.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending September 18, 1897.

Asst. Surgeon H. La Motte, placed on the retired list September 15 for physical disability.

The Journal of the
American Medical Association

Vol. XXIX. CHICAGO, ILL., OCTOBER 2, 1897. No. 14.

ADDRESS.

THE SURGEON OF OLD IN WAR.

Address in Surgery, delivered at the Sixty-fifth Annual Meeting of the British Medical Association, Montreal, Aug. 31 to Sept. 4, 1897.

BY W. MITCHELL BANKS, M.D. Edin.

Fellow and Member of Council of the Royal College of Surgeons of England; Surgeon to the Liverpool Royal Infirmary; Emeritus Professor of Anatomy, University College, Liverpool.

[Abstract from advance sheets of the British Medical Journal.]

Military surgeons in the Roman army.—The most careful investigations have failed to make out from their writings whether the Romans regularly appointed physicians and surgeons to their armies or not, although nearly every other question relating to their military organization has been treated of, sometimes very fully. What little information we possess on the subject comes mainly from mortuary or from votive tablets. Borcovicus, in Northumberland, now called Housesteads—was one of the principal stations on the line of Hadrian's wall. Here about seventy years ago, was found a monumental tablet, now in the Newcastle Museum. On it is the following inscription:

D M	D(IIS) M(ANIBUS)
ANICIO	ANICIO
INGENUO	INGENUO
MEDICO	MEDICO
ORD COH	ORD(INARIO) COH(ORTIS)
I TUNGR	PRIMAE TUNGR(ORUM)
VIX AN XXV	VIX(IT) AN(NOS) XXV

The First Tungrian Cohort is known to have been present at the battle of the Mons Grampius, and to have served at Castlecary, at Cramond near Edinburgh, in Cumberland and at Housesteads. The tablet is highly ornamented, and antiquarians hold that a rabbit and round bucklers carved in the upper part, which are emblems of Spain, show that the young military doctor was probably a native of that country. From various works treating of Roman inscriptions Simpson was enabled to find that four more tablets, in which surgeons of cohorts are mentioned, existed. They were found at Rome. One of them is a votive tablet, the inscription upon which intimates that it was dedicated by Sextus Titius Alexander to Æsculapius and to the safety of his fellow soldiers. It was cut in the year of the consulship of F. Flavius Sabinus, which is known to have been A.D. 83. As the Roman legion consisted of ten cohorts, it is interesting to know that there were not only medical officers attached to each cohort, but also one attached to the legion—a sort of surgeon-colonel, as we should call him nowadays. Three tablets have been discovered in which the *medicus legionis* is mentioned. One found at Verona was a tablet raised by Scribonia Faustina to her dearest husband J. Caelius Arrianus, medical officer to the Second Italian Legion, who died at the age of 49 years and 7 months. Furthermore, Simpson routed out of Mommsen's Latin inscriptions of Naples a tablet, now in the Dresden collection, which was found in the Elysian Fields near Baiæ, close to the Portus Julius, which was the station of a division of the imperial fleet. The inscription tells that M. Satrius Longinus, *medicus duplicatorius* to the Trireme Cupid, and the heirs of those freed by Julia Veneria erected the monument to the manes of that deserving lady. The term *duplicatorius* means that by reason of long or meritorious service he was entitled to double pay and reward.

Ambroise Paré.—Hundreds of years went past before there came upon the scene any military surgeon of note, but when he did appear he was a man of transcendent merit—the illustrious Ambroise Paré (1517 to 1590), the contemporary of Vesalius, the immediate predecessor of Harvey. For over thirty years he followed the wars under four kings of France, Henry II., Francis II., Charles IX. and Henry III. Even that miserable monster, Charles IX., loved the Huguenot surgeon, and when the awful day of St. Bartholomew came Paré was spared to tend his wretched master through the brief term of agonized and remorseful life that was given him. The description in Dumas's novel, the "Two Dianas," of the wound of the famous warrior, Duke of Guise, where the lance entered above the right eye and came out between the nucha and the left ear, breaking short off, and how Paré lugged it out, with the chance that when it did come, one terrible gush of blood would finish his illustrious patient's life and his own career at the same moment, is real history.

Amid all the splendid work which Paré did, the application of the principle of the ligature to bleeding arteries is that with which his name will be forever associated. In his time there was a fixed belief that the danger from gunshot wounds arose from the poison of the gunpowder conveyed on the bullet. To destroy this poison the treatment was to pour into the wound boiling oil in which elderwood bark had been stewed. On one occasion, not having this infernal concoction at hand, Paré used a cold mixture of yolk of egg, oil of roses and turpentine to his wounded soldiers. He passed a sleepless night from dread that this would injure those to whom it had been applied, and his delight next day was proportionately great when he found that they had had but little pain, while their wounds were free from inflammation and swelling. This was his panacea for wounds ever afterward. The world will ever believe in a glorious trio, Paré, the Frenchman, who invented the ligature; Morton, the American, who discovered anesthetics, and Lister, who introduced antiseptics.

Robert Clowes, born about 1540, served in France in the army commanded by the Earl of Surrey, and was afterward for several years in the navy. After about fourteen years in civil practice, he was despatched by Queen Elizabeth's orders into the Low Countries to attend upon the Earl of Leicester, Commander of Her Majesty's forces. He was at Zutphen when Sir Philip Sydney was killed. His last piece of service was a glorious one, he being with our fleet that defeated the Spanish Armada. It is told of him that he always kept beside him his military surgical chest, with the bear and ragged staff of his old chief Leicester on the lid. He wrote several works in English, of which the most important is entitled "A profitable and necessarie Booke of Observations for all those that are burned with the flame of gunpowder, etc., and also for curing of wounds made with musket and caliver shot, and other weapons of war commonly used at this day both by sea and land."

Peter Lowe was contemporary with Clowes and a most interesting character, born in Scotland about 1550. He obtained in 1599 from King James VI. a charter for the Faculty of Physicians and Surgeons of Glasgow, which he thus founded. His most important work is a "A Discourse of the Whole Art of Chirurgery." The first edition dated from 1597 and is one of the earliest, if not the very earliest, work embracing the whole art of surgery published in English.

Woodall's "Viaticum."—In 1628 oppeared the first work in England specially devoted to military and naval surgery. Some eleven years later the second edition appeared. A perusal of the "Viaticum" shows that Woodall was a very practical surgeon and an eminently religious man, and the way in which he mixes up pills and piety is sometimes very diverting. He enumerates the instruments for the surgeon's chest, including among others, catlings, rasors, trapans, trafine, lavatories, cauterizing irons, storks' bills, ravens' bills, crows' bills, terebellum, probes or flamules, glister sirings and "one bundle of small German instruments." Then comes a list of medicines under the heading unguentum, aqua, sol, oleum, chemicall oyles, syrups, conserva, electuariæ, etc. A long and careful description of the uses of the instruments and drugs follows. Woodall advances the cure of wounds a distinct step, once more putting us under an obligation to the soldier-surgeon. This he does by sharply attacking all through his works the inordinate and meddlesome use of strong caustics.

Richard Wiseman has been termed the Father of English surgery, and that not without reason. Born in 1620, dying in 1676, he lived in the time of Charles I., of the Commonwealth and of Charles II. He served in the early part of his life in the Dutch navy. Being, however, a devoted royalist, he served with the armies of Charles I., and after his death went into exile with his son in France. He was present at the battle of Worcester, where he was taken prisoner, and afterward confined in Lambeth House for a while. During the Commonwealth he was naturally under a cloud, and even went off to serve in the Spanish navy. At the restoration the king did not forget his old surgeon, who had done and suffered so much in his service, but appointed him his surgeon-in-ordinary and afterward sergeant-surgeon. The first edition of his work, printed in 1672, is quite a small book, entitled "A Treatise of Wounds," but it afterward expanded into a very large volume. Wiseman believed in the need for giving stimulants to a man who was in the habit of taking them, if that man was in a dire strait. When speaking of gunshot wounds, he insists upon the bullet being searched for and extracted at once.

Baron Larrey.—Up till the time of the French Revolution it is clear that military surgeons were not men of much importance, and probably had very little influence, if any, in the conduct of campaigns. But in the latter part of last century war was made on a scale which was never known before, and was made also with a rapidity and a precision quite unprecedented. Moreover the science and art of surgery had been rescued from quackery, and surgeons in actual practice were able to be of great and real service to the wounded. As a result of the vast masses of men that were hurled against each other the number of wounded after a big battle amounted to thousands, and civilization had so far advanced that it was imperative that immediate help should be given to them. So that about this time the military surgeon really became an important officer in warfare and began to have rank and pay well defined and his merits (up to a certain point) recognized.

In 1776, near the Pyrenees, was born Jean Dominique Larrey, the Chirurgien-en-Chef de la Grande Armée, the friend and body surgeon of Napoleon, the greatest military surgeon that ever lived. He studied at the medical school of Toulouse and in 1792 joined the headquarters of the Republican Army of the Rhine under Custine. Now, the ambulances of these days were obliged to remain about a league from the army and the wounded were only picked up after the fighting was done. General Custine was a man who moved his troops very rapidly, which made matters worse for the wounded. This greatly affected Larrey, who set to work and devised a new ambulance hung on springs and combining great strength with lightness. Such carriages were termed *ambulances volantes.* They could keep up with the advance guard of the army with the speed of flying artillery and they carried off the wounded almost as they fell. Larrey had early perceived the enormous advantage a wounded man got by having his fracture set or his bleeding stopped as rapidly as possible and by then getting a roof over his head before night set in. General Beauharnais, in a dispatch to the Convention, made special mention of a "Surgeon-Major Larrey and his comrades with flying ambulances, whose indefatigable care in the healing of the wounded has diminished those afflicting results to humanity which have generally been inseparable from days of victory and has essentially served the cause of humanity itself in preserving the brave defenders of our country." The staff of a flying ambulance was about three hundred and forty in number. For each division there were four heavy carriages and twelve light ones. Some had two and others four wheels and they were furnished with mattresses. In Napoleon's Italian campaigns they came greatly to the fore and the great man displayed a lively interest in them, reviewing them and causing them to maneuver before him just as if they were on a battle-field. After one of these inspections he said to Larrey: "Your work is one of the most happy conceptions of our age. It will suffice for your reputation."

When Napoleon undertook his Egyptian campaign Larrey proceeded to Toulon to organize the medical staff. So readily did professional men respond to the call made by him that he was soon able to reckon on 800 well qualified surgeons, of whom many had served in the army of Italy, and these were in addition to the medical officers actually attached to regiments. This, I think, shows the value the king of commanders set upon the health of his troops, and the trouble and expense which he was prepared to face in order to maintain it—a great contrast to the miserable way of dealing with this subject which has too long been the fashion with our military rulers. Not long after the landing at Alexandria a certain General Figuières was severely wounded. By able treatment he recovered and in gratitude for the preservation of his life he asked Napoleon to accept a valuable Damascus sword. "Yes," said the latter, "I accept it in order to make a present of it to the surgeon-in-chief by whose exertions your life has been spared." Upon the sword was engraved the words Aboukir and Larrey and the surgeon had it till the fatal day of Waterloo, when the Prussians robbed him of it.

At one period there was a total dearth of meat, and Larrey had nothing wherewith to make even a drop of bouillon for his patients. He ordered camels' meat to be used for this purpose, and when that fell short he used up the horses. Years afterward, in the the second campaign against Austria, the Imperial Guard and several other corps were crowded together in the Island of Lobau in the midst of the Danube, which Napoleon was attempting to cross. The days were roasting and the nights icy cold, and provisions became so scarce that Larrey's patients were in danger of starvation. Without more ado he impounded certain officers' horses and had them slaughtered and employed as food. As there was a lack of kettles, he employed the cuirasses of those who had been killed and made his horse-flesh soups and stews in them. Certain generals made bitter complaint to the Emperor of Larrey's proceedings, who summoned the Surgeon-in-Chief and in the presence of his staff demanded an explanation with a severe expression of countenance. "What," he said, "have you on your own responsibility disposed of the horses of the officers in order to give soup to your wounded?" "Yes," answered Larrey. He added no more, but soon heard of his promotion to the rank of Baron of the Empire.

One of the most appalling retreats, next to that from Moscow. was Napoleon's retreat from the invincible walls of St. Jean d'Acre through Jaffa. There is no doubt that at that place a considerable number of patients sick of the plague were quietly put out of their misery by opium. Alison says sixty; Sir Robert Wilson says 580. The retreat had to go on, the Turks were only an hour's march behind and nothing but a cruel death awaited these unfortunates, so that whether this were a justifiable deed or not may well give ground for argument. But, as Alison says: "History must record with admiration the answer of the French chief of the medical staff when the proposal was made by Napoleon to him: 'My vocation is to prolong life, and not to extinguish it.'"

During the battle produced by the landing of the English in Aboukir Bay, General Silly had his knee crushed by a bullet. Larrey saw that unless the leg were promptly amputated the case would prove fatal, and, the General giving his consent, the operation was performed in the space of three minutes under the enemy's fire. Just then the English cavalry came upon them. "I had scarcely time," said Larrey, "to place the wounded officer on my shoulders and to carry him rapidly away toward our army, which was in full retreat. I spied a series of ditches, some of them hedged with caper bushes, across which I passed, while the enemy, owing to the ground being so cut up, had to go by a more circuitous route."

At the battle of the Borodino, under Larrey's own direction 200 amputations were performed where there were neither couches nor blankets nor covering of any kind, and where the food consisted of horse flesh, cabbage stalks and a few potatoes.

Larrey's honorable and glorious life terminated in 1842. Napoleon when he made his will at St. Helena wrote in it: "I bequeath to the Surgeon-in-Chief of the French Army, Larrey, 100,000 francs. He is the most virtuous man I have ever known." From Napoleon's lips the words of free, spontaneous, ungrudging praise such as this rarely fell.

Military courage.—Baron Larrey's whole life shows that while absolutely devoted to the work of his profession he displayed a cool courage on the field of battle not less heroic than the more dazzling deeds of his fellow combatant officers. Not less does it mark the military surgeon of the present day. Surgeon Thomson, during the Crimean war when the army marched on after the battle of the Alma, volunteered, with his servant, John McGrath, to remain behind on the open field with 500 terribly wounded Russians, and passed three awful days and nights—these two Englishmen alone—among foreign foes, some dead, some dying, and none able to raise a hand to help themselves. Assistant-Surgeon Wolseley of the 20th Regiment at the battle of Inkerman quietly established his field-hospital in that awful place, the Sandbag Battery, and when the 150 men, who were all that remained of its defenders, were forced to desert it found at thirty paces from them a Russian battalion blocking their path, not a combatant officer left, the assistant-surgeon took command. He had not even a sword with him, but laying hold of a firelock with a fixed bayonet on it he gave them the word of command: "Fix bayonets, charge, and keep up the hill." The soldiers answered him with a burst of hurrahs, sprang forward to the charge and the next instant were tearing through the thickest of the Russians. One-half of these reached the other side alive. Surgeon Landon was shot through the spine while attending to the wounded on Majuba Hill. His legs were paralyzed, but he caused himself to be propped up and continued his merciful work till his strength ebbed away. Surgeon-Captain Whitechurch gained the Victoria Cross at the beleaguering of Chitral for the most determined courage in endeavoring to save the life of Major Baird. Of the 118 wearers of the Victoria Cross fourteen are surgeons, nearly 12 per cent. of the whole number. They stand in the proportion of 9.5 per cent. of all the officers of the army, so at all events they have contributed not less than their fair share of the deeds of valor which alone can win that glorious distinction.

The Army Medical Service today.—Today Her Majesty's Government can not induce candidates to come forward for the medical service of the Queen's army, because it has persistently treated the Army Medical Department meanly and shabbily. Today the Government of India can secure the services of the pick of our newly-fledged doctors for its army, because it has always treated the Indian Medical Service liberally and generously. Money is not at the bottom of this difficulty. The soldier-surgeons of today are the same men now that they were in the days of William Clowes, who winds up his book as I shall my address, with these verses:

When valiant Mars, with brave and warlike band,
In foughten field with sword and shield doth stand,
May there be mist a surgeon that is good,
To salve your wounds and eke to stay your blood

To cure you sure he will have watchful eie,
And with such wights he means to live and die.
So that againe you must augment his store,
And having this he will request no more

moved; detrimental, since it leaves open a pathway for the very probable introduction of bacterial ferments, even when the greatest care is exercised in the use of antiseptic dressings. When these dressings are to be relied upon their use is attended with such constant vigilance on the part of physician and nurse that frequently the largest share of the service devoted to the patient is given alone to the supervision of the wound.

Even recent statistics of the general hospitals show that a large percentage of deep wounds made in aseptic structures, closed by interrupted sutures taken through the skin surfaces, no matter what the suture material or dressing, become infected either from defective surgical operative technic, or because of exposure after the operation. One of the most important questions of general interest to all surgeons at the present time is, in what way can this percentage be reduced, and is it possible altogether to avoid the infection of wounds which have been made in aseptic structures? Since the surgical operative technic is generally well understood, based on the demonstration of scientific principles and by most surgeons carried into practical effect, it must be accepted that the faulty conditions which permit the introduction of bacterial ferments into the wound pertain less to the surgeon and the exposure involved during the operation, than that which takes place subsequently.

The time has already past which requires argumentative demonstration to prove that, when primary union fails after operation on aseptic structures where the wounded tissues can be coaptated and remain at rest, the defect lies in the lack of vitalization in the injured structures, or because of something introduced into the wound which interferes with the processes of repair. The more careful study of wound reparative processes of the recent period demonstrates the remarkable inherent vital power which pertains even to injured tissues when maintained at rest in aseptic conditions. This is the Aladdin tale of modern surgery when we recall the seeming ease with which nature disposes of large serous and bloody effusions consequent upon subcutaneous injuries, the absorption of blood clots and the disposition of devitalized structures when the wounded parts are maintained aseptically at rest. Indeed it often seems as if nature was enabled to turn these damaging factors to her credit account by utilizing all these materials in her processes of repair.

It was the knowledge of these facts that first led me, in 1870, to the belief then put in practice that aseptic animal sutures could be safely buried in aseptic wounds for the purpose of coaptation and be permitted to remain undisturbed, trusting to the inherent vital power of the structures to dispose of them subsequently as unirritating material.

My histologic studies of the repair processes incident to wounds thus treated in animals demonstrated that catgut thus buried was encapsuled by leucocytes which, little by little, invaded the foreign material, causing its subsequent disappearance, and that it left behind a more or less permanent vitalized connective-tissue band along the tract of the buried material. But for defects inherent in the histogenic structure of catgut and the extreme difficulty in making the same aseptic, catgut would furnish ideal suture material. In my wounds thus treated at this period, while primary union ensued in the deeper structures, more generally there were minute superficial abscesses at the point of the insertion of the catgut through the skin, although the skin itself had been very rigidly disinfected. Since these wounds were closed without the introduction of drainage of any type, it was clear to infer that the defect did not lie in the deeper structures, these undergoing an easy process of primary repair. As the suture material used in the coaptation of the deeper parts was of the same character as that used for the closure of the skin wound, it seemed a just criticism that the imperfect result was not due to the suture material. This was known to be aseptic from laboratory examinations demonstrating its sterility. Therefore the inference that the defective results were due to superficial infection seemed justified and this could occur only from defective protection, from extraneous infection, viz., surgical protective dressings, or a hitherto unknown something pertaining to the superficial layers of the skin itself. Since a wound treated as above described no longer required antiseptic dressings of absorbent character, the drainage tube having been dispensed with, the next step in the process seemed to me to be the protection of the coaptated wound by an adherent germ-proof dressing. After a considerable amount of experimental study I found this best attained by the use of contractile collodion in which a certain amount of iodoform was in solution (about 15 grains to the ounce). However, minute stitch abscesses were not seldom wanting, and these invariably occurred on the line of the penetration of the suture through the otherwise uninjured skin, and when very minute were more commonly found upon the site of the wound where the suture was introduced rather than upon that of its exit from below upward. This led me to a belief that a manifest profit would result by making the coaptated skin suture also beneath its surface (the subcuticular animal suture).

After a little practice it was found easy, by the introduction of the needle through the deeper layer of the skin, but exactly opposite the emergence of the previous stitch, to secure perfect coaptation of the skin surfaces without pucker or wavy lines. The wound was then sealed, almost invariably subsequent primary union followed regardless of further dressings or attention. (In 600 wounds kept under observation in my private hospital 98 per cent. were followed by primary union.)

The demonstration at the Johns Hopkins Hospital a few years ago of the constant presence of the micrococcus pyogenes albus in the dying epithelium of the skin is in my judgment one of the most important contributions to surgical science which has been made in modern times.

If the foregoing demonstrations are correct and the proof of the same ample, we may well ask, why in this long period has not this treatment of wounds been more generally accepted? I apprehend that we have not long to search for the answer, mainly because the surgeon, although accepting in an abstract way the theoretic demonstration as correct, yet, governed by the conservatism of the past, and the fear that he may enclose infectious material without any avenue for its escape, lacks the confidence in its adoption. Therefore, he takes his sutures deeply from side to side, knotting the same independently, with the knowledge that if anything goes wrong in the wound he can open the same and permit the escape of injurious substances. Still further, to assure himself that the deeper recesses of the wound, closed by his defective suturings, may not be pockets containing infective material, he places at the very bottom of the wound a drainage-tube. He attempts to aid this process still further by the application of compresses and more or less tight bandaging with the necessary result of impairing the circulation and retarding the repair processes consequent on the deficient nutrition. When he has resorted to buried sutures, from an imperfect knowledge of the proper method of application, his results have been disappointing, because he constricts rather than simply coaptates the sundered structures, and in this way devitalizes the enclosed parts. Also by trusting to the use of catgut as a suture material he often finds that he has implanted infection, because catgut is extremely difficult of sterilization.

In wounds of considerable size, subject to strain, the catgut also sometimes fails to fulfil its office as a retaining suture, since its inherent defective construction causes the early separation of its component fibers. This pertains in less degree, or not at all, to properly prepared tendon suture, the chief objection to which is the multiplicity of processes to which it is subjected in preparation. Its advantages consist primarily in not having been subjected to processes of infection, when properly taken from freshly killed animals; and secondly, when not unduly subjected to the processes of heat or chemical manipulation, it remains an unirritating material in the tissues, for two or three months, and is then replaced, more or less perfectly, by a band of living connective tissue.

The tendon from the tail of the kangaroo furnishes the best suture material. The psoas muscle is divided into many fasciculi, and each fasciculus has its independent tendon, which has its fixation in a common union at the end of the tail. A small kangaroo furnishes twenty or more uniform round tendons of suitable size for ordinary use. They are of remarkable strength, smooth and even. Their preservation consists in sun drying from the freshly killed animal and keeping dry until prepared for use. This consists of softening in 1 to 1,000 bichlorid solution, separation and selection. Then they are soaked in a 2 per cent. solution of formal, carefully chromicised and permanently preserved in carbolic sterilized linseed oil. This latter is the best preserving fluid, although not strictly an antiseptic. The tendon improves in the oil, with age. I prefer not to use it until it is a year old. When required for use, the oil must be removed, and this is easily effected by soaking in warm mercuric solution for half an hour. The tendon is then supple, and when properly handled assuredly aseptic. However, no man should use buried sutures who is not a master of modern aseptic surgical technic.

During the last year the subject of sterilization of catgut has been revived. There can be no question but that complete disinfection of catgut may be made and from this standpoint the suture be entirely trustworthy; but, as I have elsewhere pointed out, the inherent defect in catgut is in the disposition of the connective fibers of which it is composed. These necessarily cross each other at various angles and are never parallel. When twisted and dry, they are firmly held together and the suture is strong, but when wet, and they must always be in this condition in the tissues, they soften into a more or less flat, elastic band. This is the reason why the knot in catgut is untrustworthy, and the elasticity of the material permits the structures to become relaxed loosened.

In tendon the ultimate fibers are held firmly together in parallel lines, and this suture does not have even the disadvantage of twisting, which necessaril must pertain also to silk in order to make a stron thread. The sewing with catgut is not unlike fishin with a diagonally cut piece of thin silk cloth, whic has been twisted and called a line. Soon it become a flat, slippery, elastic ribbon, utterly unsuited for th required purpose.

It is very generally conceded that silk, no matte how fine, is objectionable as a buried suture, becaus of its non-absorbability, and that oftentimes on this account, nature expels it with more or less difficulty as a foreign body. Of this every surgeon of any considerable experience can bear personal testimony.

Silkworm gut is quite commonly used, especially as a retaining, superficial interrupted suture, since its component structure does not admit of its being penetrated by bacteria, and as a consequent, it is as non-irritating as wire and should therefore be classed in the same category.

Somewhat recently the practice of burying silver wire in the tissues for the purpose of coaptation, has been revived at the Johns Hopkins Hospital, and it is claimed that the result is satisfactory. But the wire thus buried, no matter how fine, must ever remain a foreign body and may become a source of irritation years after its implantation. The wire is even used as a subcutaneous suture in the coaptation of the skin, and is removed when the repair processes are complete. It is objectionable because its insertion must necessarily be in a curved line, which gives a puckered cicatrix, and its adjudged necessary removal is the best possible commentary on the belief that its retention must be a source of irritation and subsequent suffering. If the aseptic subcuticular tendon suture serves the purpose of a more even coaptation and requires no subsequent removal, its advantages are manifestly apparent.

The method of application of the buried animal suture is most important. Coaptation, retention and rest are the objects to be attained. This must be effected with the least possible damage to the tissues involved. It necessarily follows that the fewer the stitches and the least possible amount of suture material used in order to accomplish this purpose satisfactorily, the better. The fewer stitches, [illegible] every insertion of the needle necessarily injures many cells; the minimization of suture material beyond that necessary for proper coaptation lessens the amount of work incident to the repair of the structures. As far as possible knots are to be avoided, and as a consequent, the continuous suture has great advantage over the interrupted, and the amount of suture material required for each continuous stitch is greatly lessened. The constriction of the tissues enclosed by a continuous suture is more evenly equalized throughout the parts and the devitalization of the stuctures much less likely to be [illegible]

In many wounds as, for instance, [illegible] coaptation and retention of the parts is [illegible] difficult, I have found it advantageous [illegible] line of continuous tendon suture, [illegible] retention is secured without the [illegible] structures thus coaptated and, [illegible] without constriction of the [illegible] structures when thus united [illegible] which pass at right angles to their surfaces without any foreign material being interposed. A wound thus sutured is closed without any increased number of stitches or stitch-holes and holds the coaptated parts gently at rest.

The method of application of the suture in more common use for the closure of wounds, is the use of the interrupted suture, which necessarily implies a knot for each stitch and can be applied as a deeply buried suture only under very considerable mechanical disadvantage, not alone involving a difficulty of application, but necessitating a very considerable injury to the structures. Even when used it folds in juxtaposition only the tissues included in the loop of the stitch, and an undue constriction of the included structures is deemed necessary in order to prevent the gaping of the wound between the points of ligation. As a skin suture it has the well recognized disadvantage, already referred to, of penetrating the cuticular layer with its ever-present micrococcus pyogenes albus infection. Here also, to prevent the separation of the wound between the stitches, the suture is made to unduly constrict the enclosed tissues.

The continuous suture in common use (the glover's stitch) has the advantage of rapidity of application and minimization of the suture material, but it is at fault in that the action of the force is not at right angles to the divided surfaces but acts in an oblique direction, which produces a tendency to intrafold and join the opposing surfaces irregularly. By the use of the curved needle the stitches may be introduced from side to side deeply through the uninjured structures of the wound, crossing its cut edges at right angles. When this is gently drawn upon it brings the sides of the wound accurately into apposition without the interposition of suture material. For want of a better term I have called this the *parallel suture*, since it traverses the structures nearly parallel to the tissues to be coaptated. It is only a slight modification of the so-called blind running stitch in common use by the seamstress, but it fulfils a most admirable purpose in surgery.

Although it is remarkable to note how large an amount of aseptic suture may be used with apparent impunity in an aseptic wound, when necessary, it is also surprising to observe how small a quantity of suture material is really needful to hold in apposition the surfaces of a large deep wound, as in the amputation of the breast. This stitch is of equal service when applied for the closure of the abdominal wall in laparotomy, or in hernia, but for reasons already apparent it must be applied to restore and retain at rest like structures with a minimum of injury to the parts involved. Aseptically applied in aseptic structures and sealed with iodoform collodion the wound will unite, and aseptic primary union without swelling or suffering will supervene.

Agglutination as a Hemostatic Agent.—Lawson Tait is reported to be using at the present writing a new device, which has the credit of much ingenuity. A platinum wire so arranged as to carry a current of electricity is inclosed in the blades of a pair of steel forceps or any other required instrument, the wire for this purpose being insulated by a bed of burnt pipe-clay. This arrangement being perfected, a current of suitable voltage is turned on, the artery seized and compressed, and in a few seconds the tissues and arterial walls are so agglutinated that the passage of blood is rendered impossible. The temperature employed is about 150 degrees F., the fact being thus apparent that the principle involved in this device is different from that of electric cauterizing instruments.

TWO HUNDRED AND FIFTY BASSINI OPERATIONS FOR THE CURE OF INGUINAL HERNIA; WITHOUT MORTALITY.

Presented to the Section on Surgery and Anatomy, at the Forty-eighth Annual Meeting of the American Medical Association, at Philadelphia, Pa., June 1-4, 1897.

BY W. B. DE GARMO, M.D.
PROFESSOR OF SPECIAL SURGERY, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.
NEW YORK.

The 250 operations here reported have been done upon 216 patients; 34 of the cases having been operated on on both sides. Fifty-two of the patients were females, 164 were males. I am quite sure that no one can accuse me of having selected my cases, when their ages and conditions are considered. Fifty-five of the patients were under 14 years of age, 43 were between 14 and 25, while 118 had passed their 25th year. Of the latter number, 8 were between 60 and 70, 6 between 70 and 80 and 2 were over 80 years of age. The youngest child operated on was 5 months old, and this is the first instance in my experience where I have been obliged to operate on a child less than 1 year of age. The operation was for strangulated scrotal hernia on the right side. The left was operated on at the same time for a large scrotal hernia, and the child made a perfect recovery in ten days.

The age limit for operation on these cases does not seem to have been reached in either direction, as the oldest patients operated on seemed to stand the operation as well, and recover as promptly as those operated on in early life.

Ninety-three of the cases had scrotal hernia; 55 were irreducible, 17 were strangulated and 178 were reducible at the time of the operation. In fifty-five of the cases it was necessary to excise more or less omentum, and this was done by tying off with multiple silk ligatures, in the manner described by me in the *Annals of Surgery*, June 2, 1895. I am not disposed to change this method now that I have a total of seventy cases without a death, which seems to prove its efficiency and safety.

The largest hernia operated on was two feet in circumference, reaching two-thirds of the distance to the knee of the patient, who was a man 53 years old. The tumor contained large and small intestine, a quantity of omentum and a distended bladder. This man had told me that he had difficulty in urinating unless he pressed the tumor forcibly against his thigh with his hands, but the exact condition of the bladder did not occur to me until after the operation. Twenty-four hours later it was found that he was passing very little urine and as the catheter could not be introduced, the bladder was becoming enormously distended. Forty-eight hours after the operation the bladder was therefore opened through the perineum and free drainage established. Notwithstanding the extent of the secondary work done upon him, the man recovered from his hernia operation by primary union and has now remained cured for two years.

The success of the Bassini operation is believed to be largely due to two facts: That all abnormal structures are cleared out of the canal; that two muscular layers are brought down to form a new posterior wall.

Aside from the hernial sac and its contents, I have found in the canal in three instances the ovary; in nine cases the testicles, and enlarged veins in a number of males. A young woman 30 years of age, accustomed to all athletic sports and in perfect health, had in both canals masses of varicose veins having every appearance of extreme varicocele as found in the male. These were ligated and cut away, but their cause and actual source of supply remained unknown.

Bunches of extra-peritoneal fat have been frequently met with in the canal in masses larger than one's thumb, and in one case as large as a good sized hen's egg. This man had scrotal hernia on one side and was supposed to have complete inguinal hernia on the other, but no hernial sac was found, merely this mass of fat coming down in front of the peritoneum. It was loose in the canal, hanging by a pedicle. and he could therefore push it up above a truss pad that he had been accustomed to wear.

It is not a very uncommon thing to have men tell me that formerly they were fat, and upon getting thin they have developed hernia. Doubtless, these are cases of the character just described, where previously the canal had been dilated by extra-peritoneal fat, and when this was absorbed a true hernia had come through the canal. I am quite sure that cases of this character are a far more common source of hernia than is generally supposed.

Cysts have been found in the canal in four cases and this does not apply to those frequently found in the scrotum just above the testicle. In one case it took the form of multiple small cysts, the whole resembling a small bunch of white grapes; this in addition to a well developed scrotal hernia. The length of time that these cases have been under treatment is of interest and importance. The time required for the complete healing of the case and the day upon which the patient first leaves his room or the hospital is considered the day of discharge.

Of the 250 cases 207 healed by primary union, and these patients were allowed to leave their beds by the tenth day, and in most instances left the hospital by the fourteenth day. Fifty-three healed by secondary union. The shortest stay in the hospital was eleven days. This was following an operation on a physician who, on his own responsibility during my absence from town, left the hospital and took a train for Detroit on the evening of the eleventh day. I have been assured by him that he suffered no inconvenience, nor did it seem to compromise the result in the least. I have only had six patients out of the total number who have required more than twenty-eight days for complete recovery.

In the suppurative cases the infection has seemed in almost every instance to start immediately beneath the skin and has not extended to the deeper tissues. In one instance the wound became infected by a gonorrheal discharge, the existence of which was not known at the time of the operation.

Fat patients, whose skins have been abraded by truss wearing, are peculiarly liable to suppuration, even when great care has been taken in the preparation for operation.

Contrary to my own expectation, in but a single instance has recurrence taken place among those cases in which there was suppuration, and in this one it is known that the failure was in no way due to a lack of primary union.

Suppuration in children under 14 years of age has been seen in only one instance in fifty-five cases; children, apparently, not being at all liable to this accident. In the case noted it was a second operation where there was considerable matting together of the tissues.

The double operations were in every instance done at the same time, as also some cases of inguinal and umbilical hernia. One patient, a man of 52 years, was operated on for double inguinal and right femoral hernia on the same day and has remained cured of the three hernias nearly two years.

Suture material.—In my early operations by this method I did not have faith in the lasting properties of kangaroo tendon or chromicized catgut, and from my experience with silk I was somewhat suspicious of that and was therefore led to use silkworm gut for closing the aponeurosis of the external oblique. This was used in twelve cases and in four of these considerable trouble was afterward experienced by the sutures coming out. In eight of the cases they were perfectly retained and have caused no irritation of the tissues. In one instance sutures came out nearly one year after the operation. This material was, therefore, entirely abandoned and since then I have used kangaroo tendon exclusively. In none of these cases, however, has there been a recurrence of hernia, even when the sutures came out. One man was operated on two years since where ordinary catgut was the suture material. No recurrence has taken place.

I am not prepared to disprove the statement of some of my friends that catgut, chromicized or plain, is just as good as kangaroo tendon, but prefer that they should first show an equal number of cures before I change.

One thing in connection with the presentation of this series of cases, I feel that I have reason to congratulate myself upon, and that is that there have been no deaths. I have not gone to the trouble to look over the literature on the subject, but I believe this to be the largest number of operations ever reported for the cure of hernia without a single death.

In one respect I may be liable to criticism on this point, for while I report seventeen cases operated on when the hernia was strangulated and when recovery and cures were effected I do not report two fatal cases operated on during the same period of time. This report relates to the Bassini operation for the cure of inguinal hernia, and has nothing to do with the fatality of strangulated hernia. If the canal has been closed by the Bassini method and the patient survives. then certainly it belongs to this report; otherwise, not.

Next in importance to its safety is the consideration of the permanence of the cure. In a paper on this subject, before this body, at Baltimore, in 1895,[1] I ventured to predict that the permanent cures would be 90 per cent. I am convinced that this estimate is too low, and do not hesitate to advance it to 95 per cent., with five years duration of cures after the operation, but this statement is premature and I am not here to argue this point, but to state the facts as they exist and allow each one of my hearers to draw his own conclusions. None of the present series of cases have been operated on more than three years. One hundred and fifty of them, however, have gone over one year since the operation and in no case, except of actual reccurrence, has a truss been applied. Out of the 250 operations I have had six recurrences. Three others are under supicion, but not sufficiently so to warrant the application of a truss. Of the six recurrences three have been reoperated on, and apparently with success. This leaves only three actual recurrences. By notes made at the time of the first operations it is believed that the real cause of failure has been known in every case. For a clear comprehension of the subject these cases must be briefly considered.

---

[1] "A Note on the Advance in the Surgical Cure of Hernia," Journal of the American Medical Association, July 13, 1895.

Case 1.—My first recurrence was in a perfectly healthy young man 20 years of age, operated upon on June 3, 1895, for scrotal hernia of recent origin. The sac was tied off at the peritoneal surface and removed and the operation completed in the usual manner. He left the hospital on the fourteenth day, perfectly healed and four months later fell into an open trap doorway, falling violently upon his abdomen across the edge of the floor. One week later a bulging across the line of incision, and he was reoperated on Feb. 6, 1897, so far with apparent success.

Case 2.—The second recurrence was in a boy 6 years old, operated on for congenital hernia June 4, 1895. Primary union followed and he left the hospital on the fourteenth day. Five months later he developed a small protrusion at the line of the incision while struggling violently with the family physician and the father, who were trying to remove a piece of wood from the urethra. Reoperated upon Feb. 15, 1897, with apparent success.

Case 3.—The third recurrence was in a man 39 years of age, who had a large and troublesome hernia for many years. Operation Nov. 8, 1895; he left the hospital on the fourteenth day, completely healed. This patient was not seen until after his entrance for the operation, and it was not discovered that he suffered from an enormous varicocele on the same side. It was noticed at the time of the operation that the cord was large, but nothing was done for it. As soon as the man was on his feet it was seen that the varicocele was very liable to reproduce the hernia, which it did within six months of his leaving the hospital. Reoperated on May 11, 1897. The varicocele and all abnormal veins in the canal were removed. The cord was found to be fully as large as one's finger and was reduced to about the size of a lead pencil. This man has just left the hospital entirely healed. There is no apparent change in the circulation in the testicle after this change in the size of the cord.

Case 4.—Man, 37 years of age, weighing 225 pounds, had left irreducible scrotal hernia the size of a small cocoanut. Upon first examination believed to be a mass of omentum; the operation revealed the fact that it was largely bowel. Proved to be the sigmoid flexure turned out through the canal without peritoneal covering. Had not the opening been made to the internal ring it would have been mistaken for the hernial sac and opened. This man had fatty degeneration of the abdominal muscles to such an extent that the sutures would tear through the tissues readily under moderate tension. Hernia gave evidence of recurring in about six months and a light truss was applied and will be continued. Second operation not advised.

Case 5.—Man, 40 years old, six feet five inches tall, weighing 225 pounds, but not healthy looking, had had left scrotal hernia since early childhood, and irreducible for many years. A large mass of hypertrophied omentum was removed. Case was very difficult for operation and in closing the structures, by mistake, the aponeurosis of the external was carried under the cord for a part of the distance on the first row of sutures. On account of the tedious previous work and the condition of the patient time was not taken to correct this. Recurrence in three months.

Case 6.—Man, 55 years of age, of frail build but apparently good health, had had right inguinal hernia for several years, which proved rather rebellious under truss treatment. He took ether nicely, but after the canal was opened seemed to collapse, pulse dropping to 40 and respiration very feeble. Omentum firmly adherent to upper part of the canal. The necessity for a prompt termination of the operation seemed evident, and the upper part of the sac with adherent omentum was inverted; a suture of kangaroo tendon was placed so as to bring the peritoneum, transversalis and internal oblique as closely around the cord as possible, and the suturing of Poupart's ligament to the deep muscular structures was done in the usual way, except that it was hurriedly done. The patient was only on the table twenty-five minutes and came promptly out of the ether in good condition; a small quantity of ether had been judiciously administered. Patient made a rapid recovery, but showed evidence of recurrence within three months. Light truss applied and now being worn.

Thus, of my six recurrences, two were caused by unusual violence, two on account of undue haste in closing the canal because of the condition of the patient. One was a sigmoid hernia where there was a fatty degeneration of all muscular structures. One was undoubtedly reproduced by a very large varicocele overlooked at the time of the operation.

Three of these cases have already been operated on and, it is believed, cured. Of the remaining three, it is believed that only one is absolutely incurable, and that is the one with fatty degeneration. They are all vastly improved over their condition previous to the operation.

In closing, I feel that I can safely say, that by the Bassini operation and the present advanced methods of surgery, inguinal hernia has been taken from the list of incurable and placed on the list of curable affections.

Operations, 250; patients, 216; both sides, 34; females, 52; males, 164.

Under 14 years of age, 55; 14 to 25 years of age, 43; 25 to 40 years of age, 55; 40 to 50 years of age, 29; 50 to 60 years of age, 18; 60 to 70 years of age, 8; 70 to 80 years of age, 6; over 80, 2.

Position.—Right, 154; left, 96; Double, 34.

Kinds.—Scrotal, 93; reducible, 178; irreducible, 55; strangulated, 17; retained testicle, 9; displaced ovary, 3.

Method of healing.—Primary union, 207; secondary union, 43.

Omentum was excised in 55.

Cures, 244 (recurrences, 6); reoperated, 3. Total, 247.

Discharged.—Shortest time 11 days, longest time 84 days. By the fourteenth day, 114; twenty-first day, 84; twenty-eighth day, 12; thirty-fifth day, 4; fifty-sixth day, 1; eighty-fourth day, 1.

56 West Thirty sixth St., New York.

DISCUSSION.

Dr. H. O. Marcy of Boston—I wish to point out the essentials as to the cause of cure from an anatomic standpoint. The reason that we are not all the subjects of hernia is because the inguinal canal is at a right angle to the intra-abdominal pressure. I have operated more than four hundred times, sometimes as early as three months, and as late as 80 years. During all this experience, even where the intestine itself has been involved, I have never seen a case approach the danger line. I am sure that over 90 per cent. of my cases have remained permanently cured, and I consider all other operations are hardly worthy of discussion. You should all become familiar with the technique of this operation and with the details referable to it in practice. There are three or four million trusses worn in this country alone, and these people should be restored to usefulness. It can be done and should be done. As to the age, I have operated on over thirty patients beyond 60 years of age, and they have improved and been cured as easily as anyone else. Those in middle life and young people should always be operated on.

Dr. A. J. Ochsner of Chicago—I wish to mention the age limit. It is apparent to everyone who sees many hernias that patients will do very well with a truss until they become afflicted with urinary disturbance, and then they will begin to suffer and their truss will no longer be satisfactory. When Dr. White's paper on the "Treatment of Castration" was published it occurred to me that it would be a wise thing in these cases, instead of doing the Bassini operation, to make a section of the cord or to castrate on the side of the hernia. In these cases I think that castration or a ligature of the cord on the side of the hernia would have the same result as Dr. White has noticed in his cases. He has found that urination has been made easy while the difficulties from which the patient had suffered previously all disappeared. In addition, the increased pressure on the hernial ring was also decreased. It is too early yet to consider these cases as permanent cures. For many years I have treated many hundred little boys with inguinal herniæ and have found that many of the cases also suffer from phimosis. In every case less than twelve years of age it can be cured without herniotomy, but by simple circumcision and placing the patient in bed for several weeks afterward with the foot of the bed elevated at an angle of 45 degrees. I do not think we should operate on children under 12 years of age unless this condition has been considered, and I think the time limit important.

Dr. B. Merrill Ricketts of Cincinnati—I would like to ask if the members have ever come in contact with hydrocele and undescended testicle.

Dr. W. Frank Mayo *of Rochester, Minn.*—There are some things about the Bassini operation which are somewhat different from that of Dr. Marcy. It has always seemed to me that the important point in the Bassini operation was the method of placing the sutures. His method of suturing the canal in a single layer from the inside to the outside is liable to failure without some such suture as the metallic suture. Bassini's operation divides the cord. I would like to call attention to the catgut which has been introduced in these cases. The cases which have relapsed have always been cases which have suppurated. Dr. DeGarmo states that he has had only one case suppurate in children. This has been my own experience and I suppose it is because the parts are more resistant, although there are a certain number in which suppuration will certainly take place.

Dr. E. D. **Ferguson** of Troy—If the suppuration is superficial and does not involve the fibrous layers of the skin, your results will be good; if it is deep and does involve the fibrous layers it will probably fail. If you use the metallic suture it is permanent. We want sutures to last a certain length of time, and they should hold the parts together thoroughly for several weeks, but at the same time they should not be a permanent suture. Whatever the nature of the suture may be, it is a question of restoring the obliquity of the canal for a sufficient length of time to establish firmness, and a question as to whether a certain suture may be used is a matter of minor importance. The question of establishing the union of the fibrous layer on the posterior wall of the canal, especially when pressure comes from the abdominal side, is an important one. This is what Dr. Marcy claimed before Bassini operated at all.

Dr. **DeGarmo** of New York City—We are indebted to Dr. Marcy for his demonstration as to the causes of hernia. There is a question about his having preceded Bassini in the operation of restoring the obliquity of the inguinal canal, but so far as I know Dr. Marcy was the first one to do this. Bassini uses silk in his operation. I have twice excised the testicle on the side of the hernia. As to phimosis, twenty years ago there was something written on this point. If a child has phimosis circumcision should be done. If we go to a Hebrew institution where the children have been circumcised in early life we will find as many cases of hernia as anywhere else, but I do not wish today to advocate operating on infants in all cases, although it will be well to do it in many. Many children 7 or 8 years of age can not be cured by a truss and they should be operated on. I have seen hydrocele associated with undescended testicle and it was as large as a hen's egg. In this case the testicle was brought down, but I have seen instances of undescended testicle where the cord was too short. I merely clear the space outside of the perineum and cover muscular tissue over it. In one man there was very marked relief by this method, but if the cord is long enough the testicle should always be brought down. We are perfectly safe in leaving the testicle outside of the peritoneal cavity and in the muscular structure. Tendinous structures need about six weeks for union, and I would like to use something which is not absorbed, but this is difficult to do. Kangaroo tendon suits me very well.

ON THE TECHNIQUE OF PNEUMOTOMY.

Presented to the Section on Surgery and Anatomy at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY CARL BECK, M.D.
PROFESSOR OF SURGERY, NEW YORK SCHOOL OF CLINICAL MEDICINE; SURGEON TO ST. MARK'S HOSPITAL, ETC.
NEW YORK, N. Y.

While the surgical principle, "*Ubi pus, ibi evacua,*" is nowadays held up more than ever before even in those parts of the human body that are accessible only under great difficulties, there seems to be some exception in regard to pus accumulations in the lungs, although they are by no means of rare occurrence. This lack of enthusiasm in attacking lung abscesses by the surgical knife is apparently caused by the widespread prejudice that they are all of a tubercular character and could consequently not be cured by simple evacuation. But while there is no doubt that the presence of one tubercular abscess necessarily presupposes the affection of a more or less extensive area of lung tissue, the nature of which would certainly be but little influenced by the opening of the single abscess, still there are many abscesses which are caused by preceding inflammatory processes, by suppurative bronchitis, bronchiectasy, etc. These are of a non-tubercular character and are curable, if treated after true surgical principles. If this fact were fully realized, the medicamentous armamentarium of euthanasia would be given up in many cases of alleged phthisis. And here is the salient point in the difficulty of the diagnosis. Still, the diagnosis of the presence of lung abscess is much easier than its localization.

The presence of copious purulent expectoration, its admixture of elastic fibers and blood pigment, the history of a preceding inflammatory process, particularly of pneumonia, which ran no typical course, the physical signs of the presence of a cavity, the absence of tubercular manifestations, etc., should point to the existence of a lung abscess. As to localization, it has to be borne in mind that while cavities of the apex contain more or less air, those situated further below contain purulent secretion only. If in the latter variety expectoration is copious, so that the cavity becomes evacuated, the respiratory sounds become tympanitic on percussion and are well perceptible on auscultation. If, on the contrary, the cavity is filled up, there is complete dulness and the respiratory sounds are hardly, if at all, audible, pectoral fremitus also being entirely absent.

Cavities of recent origin are easier localized than old cases, not only because the course of the precursory disease furnishes some elucidation, but also because the physical symptoms are much more clearly pronounced. Old cavities are, with few exceptions, deeply situated and can, according to clinical experience, generally be reached below the lower angle of the scapula.

Exploratory puncture, while absolutely reliable in pyothorax, often fails to disclose lung abscess and has, therefore, to be replaced by exploratory pleuro- or pneumotomy. (Compare the writer's article on exploratory pleurotomy and resection of costal pleura, *N. Y. Medical Journal,* June 15, 1895.)

The principles of treatment are governed by the same as those which are determining in any case of abscess, that is, thorough evacuation and drainage. This can only be done well by making a wide opening in the chest wall. To accomplish this the resection of at least two, preferably of three or four ribs is required.

The technique is as follows: Thorough asepsis is just as necessary as in any other operation. Particular attention must be given to the skin of the patient and to the hands of the surgeon, scrubbing with green soap first for three or four minutes, then washing with alcohol or ether, and subsequently with bichlorid, 1 to 500. To sterilize the skin of the patient thoroughly, it is advisable to cover the field of the operation with a poultice of green soap. If there is enough time, the poultice may remain for twenty-four hours. I regard this an essential factor for the disinfection of the skin, because I do not believe that under ordinary circumstances the epidermis, which shelters a multitude of pathogenic bacteria, can be rendered sterile by the usual methods of disinfection, which are generally not carried out longer than from ten to fifteen minutes. A period of twenty-four hours gives the soap a chance to permeate the epidermis thoroughly, so that scrubbing on the following day is much more effective. Sometimes indeed the poultice macerates the epidermis so that it can be wiped off easily. All the appliances needed at the operation must be sterilized; the instruments, ligatures, etc., in boiling soda solution, and the towels, sponges, etc., in steam.

As a rule the eighth rib is selected. The incision, about five inches in length, should be made in the center of the selected area, and should be carried directly down to the periosteum of the rib. An incision is then made along both borders of the rib, and the periosteum, both in front and behind, is raised by means of a periosteal elevator. Having freed the periosteum, the elevator is pushed beneath the rib, between it and its posterior periosteum, and allowed to rest on both edges of the wound. With a blunt hook the tissues are retracted along the rib toward the axilla, and by means of a bone shears the rib is cut between hook and elevatorium. Next, the elevatorium is pushed toward the sternum, forcing the rib from the last fragment of adhering periosteum; the retractor is inserted into the end of the wound, and with the scissors the rib is cut through on the other side. Now the costal pleura underneath is incised and a large aneuryism needle is introduced through one of the pleural incisions and conducted underneath the costal pleura to the other. With strong silk sutures the tissues, containing fascia, muscles, periosteum, costal pleura, and intercostal arteries are ligated close to the surface of the rib; then a vertical incision is made through the tissues between the two ligatures, thus creating a wide opening. By retracting the skin forcibly the skin incision can be utilized for the resection of the rib above. If, as rarely occurs in these cases, adhesions should be absent, the lung may collapse, so that it is found impossible to draw it forward. Then the final incision has to be deferred for a day or more. If the lung moves freely beneath, it is essential to shut off the pleura by packing gauze tampons around the margins in order to prevent infection from the escaping pus. This procedure renders suturing of the pleura to the lung, as well as artificial formation of adhesions by the use of caustics, unnecessary. Especially if the abscess is located superficially, infection of the pleural cavity might be caused by the stitch-canals. The further steps must be undertaken with a great amount of care and patience. If palpation of the pulmonal area has failed to give information, an exploratory needle of moderate size may slowly be pushed into the lung. If necessary this must be repeated on different points. If the focus is not reached by the needle, the pulmonal pleura is carefully divided and the thin, slightly red-heated point of a Paquelin cautery thrust into the suspected portion. I found it advisable to construct a thin director, made of platinum, which fits round the heated platinum tip of the Paquelin cautery, just as a stylet fits to a trocar. After tip and encircling director have perforated the lung tissue, the tip is withdrawn and the director left *in situ* to ascertain whether any pus appears at the groove of the director. If so, a small Péan forceps is introduced and the opening is gently dilated. The great advantage of the Paquelin cautery is that it prevents infection. The exploratory needle, while entirely harmless in pyothorax, is apt to cause infection in the lung tissue.

After the cavity is exposed, no irrigation nor exploration with the finger is advisable, as these procedures might provoke hemorrhage. A narrow strip of iodoform gauze is carefully introduced into the cavity. The pleural cavity is then once more thoroughly cleaned and revised, and packed with iodoform gauze. The whole is protected by a large piece of moss-board. The dressing need not be changed more frequently than every second or third day, except there should be signs of retention of pus. It is advisable to tell the patient to blow at intervals with his mouth and nostrils closed, which helps evacuation of the purulent discharge.

The patient, if at all able, should get up after a few days. During the first few days of the after treatment small doses of morphin are administered for the purpose of immobilization, especially when cough is present. If the pulse be weak, strophanthus and caffein may be added. Nourishment must be given frequently and in small quantities.

Anesthesia should be administered only if the pulse be strong enough, which is an exceptional circumstance in such cases. Ether being contraindicated in respiratory disturbance, only chloroform can be employed; and I need not call attention to the danger to which the use of this paralyzing drug subjects the heart. Since the operation does not take very long for a well trained surgeon, it would be better to use an ether spray or ethyl-chlorid, and to give a morphin injection before the operation. Even cocain has its dangers. If chloroform is employed, only a few drops should be poured into the mask at a time, and the pulse, the respiration and the color of the face should be very carefully watched.

My own experience comprises four cases of lung abscess, all of which recovered. In two of the cases the diagnosis of pyothorax, and in one of subphrenic abscess had been made before resection. Only in one case the diagnosis of lung abscess was made before operation, wherefore I may be permitted to give its history:

M. B., 31 years of age, merchant, Austrian by birth, had pneumonia when ten years of age; in November, 1895, pleuropneumonia, after which cough and copious expectoration of an offensive odor remained; once in a while hemoptysis, chills and dyspnea. The treatment had consisted in the administration of expectorant mixtures and inhalations of turpentine. On Feb. 21, 1896, the following was present:

The anemic patient shows a flat thorax, which expands symmetrically. The left lung is normal. On the right side anteriorly below, tympanitic sounds, râles during inspiration. Posteriorly below, extensive dulness. Correspondingly bronchial breathing and râles. Above the apex of the heart systolic murmur. Pulse soft, 110. Urine contains large quantities of indican. Sputa muco-purulent, about 180 c.c. in twenty-four hours. Pus corpuscles in abundance, also elastic fibers. On the *following day, since the patient expectorated* but little, the dulness is much more pronounced and the respiratory sounds are less audible. After the patient had coughed considerably, the bronchial respiratory sounds become more audible again above the region of the ninth rib, where sometimes amphoric breathing can also be perceived.

On Feb. 24, 1896, the weak patient slightly anesthetized with chloroform and an incision made over the ninth rib, extending from the posterior axillary line to the transverse process of the ninth dorsal vertebra. After the ninth, eighth and tenth ribs, together with their soft tissues, were resected, the lung collapsed slightly, but soon expanded again. The pleura was packed with aseptic gauze and then an exploratory needle was pushed forward into the center of the exposed area. About one inch behind the pulmonal pleura gray pus, which contained air and which had a very offensive odor, was aspirated. After the opening was dilated, the needle having served as a guide, a little over an ounce of pus was discharged. While the cavity was packed with a small strip of iodoform gauze, the patient coughed excessively. There was no hemorrhage and no signs of shock. Twenty-four hours after the operation the patient had a temperature of 101 degrees F., a soft pulse of 120 and a respiration of 30. There was considerable cough and copious expectoration with foul odor. Thereafter the temperature went down gradually and the patient improved rapidly. From March 6 the patient was out of bed.

The wound was obliterated by the end of April, two months after the operation. Gain in weight twenty-three pounds. No cough, pain nor fever; once in a while a slight cough only, with expectoration of clear mucus. According to the latest news received from the patient he is perfectly well.

While this article is in print, I had an opportunity to observe another case of this type. Being of unusual interest, it may be reported in addition:

Annie S., four years of age, showing a fair family history, always had a rhachitic appearance, according to Dr. S. Ellsberg, to whom I am indebted for his report. The patient also suffered more or less from catarrh of the upper air passages. About March 1, 1897, she took sick from pneumonia (temperature of 106 F. in the beginning). First the left upper lobe was affected. On the seventh day normal temperature. March 9, renewed attack of fever, 105 F., which with slight fluctuations lasted until March 24, the left lower lobe now being affected, and five days later the right upper lobe participating. After March 24 the temperature oscillated between 100 and 101, sometimes exacerbations up to 104 taking place. Great emaciation. April 5 the diagnosis pyothorax was made, and a large amount of pus discharged by simple incision. Full recovery five weeks later.

About June 15 the patient was attacked by violent cough and slight elevation of temperature. First the diagnosis whooping cough was made, but Dr. J. Winters, who was called in consultation, discovered that there was still a small accumulation of pus in the pleural cavity, which had finally perforated into a bronchus. He advised immediate resection of a rib, but shortly after the patient expectorated a considerable amount of pus during a violent coughing spell. On the following day the temperature became normal and the patient improved so rapidly that recovery was again thought to be perfect. After one month's euphoria the child became feverish again and had violent attacks of coughing, during which she became cyanotic. The diagnosis pyopneumothorax was made, and Drs. Winters and Ellsberg insisted most strongly upon a resection now, to which, finally, consent was given.

On August 27, when I saw the patient for the first time, I found the following state present: Anemic, thinly built girl; thorax expands symmetrically; nothing abnormal is found on the right side; on the left side, above the fifth intercostal space in the posterior axillary line a large scar, which bulges forward during coughing; posteriorly below slight dullness; bronchial and amphoric breathing above the dull area; the sputa are muco-purulent, and contain blood sometimes, especially after a violent cough; elastic fibers and pus corpuscles in large quantities; pulse 144, temperature 101 F.

August 30, after the patient was slightly anesthetized with chloroform, a piece of the sixth rib two inches long, which was situated below the old scar, was resected, the scar tissue being removed at the same time. When the pleura was incised brown pus and air escaped under considerable noise. Slight shock. The anesthetic was dropped at once. The lung did not collapse, this probably being due to the adhesions formed during the healing process of the pyothorax. By introducing the pleural speculum a canal leading into the lung tissue could be seen. Its gentle dilatation with a Péan forceps revealed the presence of a cavity of the size of a small apple, which was wiped out carefully with gauze mops and finally packed with iodoform gauze. The child made a rapid recovery, three weeks after the last operation the opening being closed.

DISCUSSION.

Dr. Thomas H. Manley of New York—Dr. Gaston of Atlanta, has done much work in this line. These cases are always difficult to deal with, and it would seem to me to be a question, when we have an empyema or a pus formation in the pleural cavity, to determine as far as possible first whether that formation is due to the formation of the cells of the pleura or whether it be an interstitial abscess of the lung itself. That being possible to decide, whether or not in some cases it might be advisable, especially as the patient is exhausted and the question of an anesthetic is important, to resort to an exploratory incision, and then inject and flush the cavity, closing the opening with drainage. I would like to ask whether or not we can not succeed quite completely in benumbing the parts with cocain and using ether spray on the surface; also, whether in certain cases it is not important to spare the resection of the rib.

Dr. Beck—With regard to the exploratory puncture there is only one thing to do, and that is a resection of the rib. As soon as this is done you can easily find your way into the abscess. As to the anesthesia I know of many cases where death has occurred before the knife had been put into the abscess. Suits for damages have not been infrequent. With regard to the regeneration of the bone after resection of a rib, I am very glad to say that ribs have been known to have regenerated nine months after operation as has been shown by the X-Rays. I believe the X-Rays should be employed after every operation of this kind.

THE SURGICAL ENGINE AND ITS USE IN BONE SURGERY.

Presented to the Section on Surgery and Anatomy, at the Forty-eighth Annual Meeting of the American Medical Association held at Philadelphia, June 1-4, 1897.

BY MATTHEW H. CRYER, M.D.
PHILADELPHIA, PA.

The requirements of a satisfactory surgical engine are, first, that it be so geared that the velocity of the cutting tool is from four to six thousand revolutions per minute, which speed is to be maintained under varying pressures. The hand-piece (the chuck which holds the instrument) should be light, capable of easy adjustment, and so arranged that the instrument fixed in it may be carried with readiness into the recesses of deep cavities. There should be no undue vibration of the instrument while held to its work, as this will lessen tactile recognition of the nature of the tissue being cut. The motive power should be so arranged that it is under perfect control and produces steadiness and uniformity of speed. The hand-piece and its several parts, with the instruments used, must be of such character that perfect sterilization can be readily accomplished.

Surgical engines of several designs have been in use for many years, but, strangely enough, few general surgeons appear to have availed themselves of the advantages to be derived through their use. There is scarcely an operation upon osseous tissues that could not be more quickly and accurately performed by means of the engine than with any of the hand instruments used. Many of these latter are crushing instead of cutting instruments.

Objections to some of the older forms of engines were not without good foundation. As they were chiefly notable for their faults of design and of construction, the deficiencies in mechanical performance might be accepted as a necessary evil, but the impossibility of complete sterilization was an objection not so easily disposed of. These serious drawbacks have one by one been corrected, until in its present form the engine combines all of the features described as requisites of a correct machine. It is simple in design and accurately built, so that there is little liability of the mechanism getting out of order.

The present engine is new in nearly all of its features; it is simpler in design, lighter in construction, and its parts are readily detachable to permit of packing in a small case, a box not larger than those made for croquet sets. The hand-piece is designed with a twofold object, first, with a reference to the mechanical, second, to the pathologic elements involved. It is sufficiently rigid to carry its tools steadily while operating on dense bone, and may readily be rendered perfectly aseptic. The latter point is repeatedly emphasized because of the serious objection to previous hand-pieces, involving the existence of spaces which commonly retained septic matter. That portion of the engine which transmits the power from the large wheel to the pulleys of the hand-piece requires no description other than that of the illustration. The engine is driven by an electric motor of one-sixth horse-power.

For office practice, and when driving by electric motors, the upright shaft from above the crank and the "arm" may be attached to a bracket. This plan is excellent when the engine is used in bone surgery of the nasal fossa or other light surgery about the face or ears; but for hospital and heavy work it is better to use the stand, as it can be moved about to suit the convenience of the operator.

The hand-piece has undergone complete change, in order that the several appliances used can be made absolutely aseptic and kept so throughout the operation. All that portion of the instrument which includes the hand-piece and its wrist-joint attachment, except the cord, can be thoroughly boiled under pressure. The hand-piece proper is detached from the pulley after the parts have been sterilized: the pulley is adjusted and the cord placed in position: the hand-piece or pieces, after sterilization, are kept in a tray containing a carbolic acid or lysol solution until used. When the surgeon is ready to use the instrument, his assistant holds the pulley attachment in such a manner that the hand-piece can be adjusted without the hand coming near the cord or that portion upon which it works. For ordinary surgery, one hand-piece is quite sufficient, as any number of instruments can be easily adjusted by opening the key-latch and inserting the sterilized instruments, which are also placed in a tray containing the antiseptic solution. For opening the brain-case it is preferable to have two hand-pieces, one with the small trephine and one with the spiral osteotome and guard adjusted. It saves time, an element of some importance in these operations.

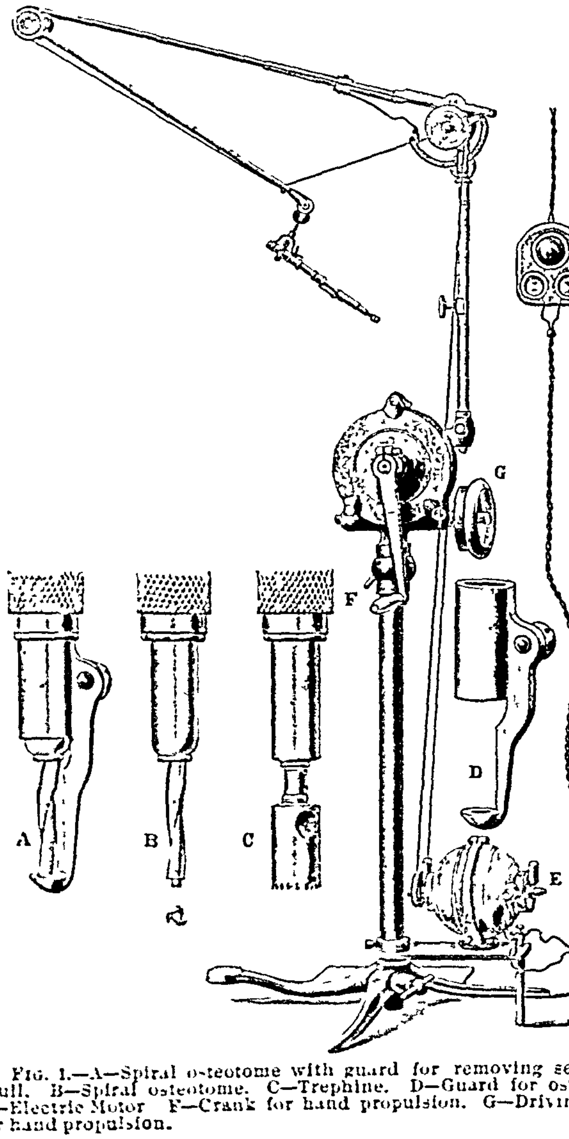

Fig. 1.—A—Spiral osteotome with guard for removing section of skull. B—Spiral osteotome. C—Trephine. D—Guard for osteotome. E—Electric Motor F—Crank for hand propulsion. G—Driving wheel for hand propulsion.

Among the various uses for which the surgical engine is well adapted, is the removal of carious bone from almost any of the bones of the body. This may be done without danger of injuring the surrounding tissue, for, when properly manipulated, operations may be performed without injury to the periosteum of the bone operated on.

The engine has also been most successfully used in mastoid and other operations on the temporal bone and upon the nasal fossa; also for removing caries and necrosis of the maxillary bones. The removal of even the greater portion of these bones may be accomplished without external incisions, which gives greater advantage over the older methods of operating with the cutting forceps and saws, as the parts are left smooth and rounded, not jagged and roughened.

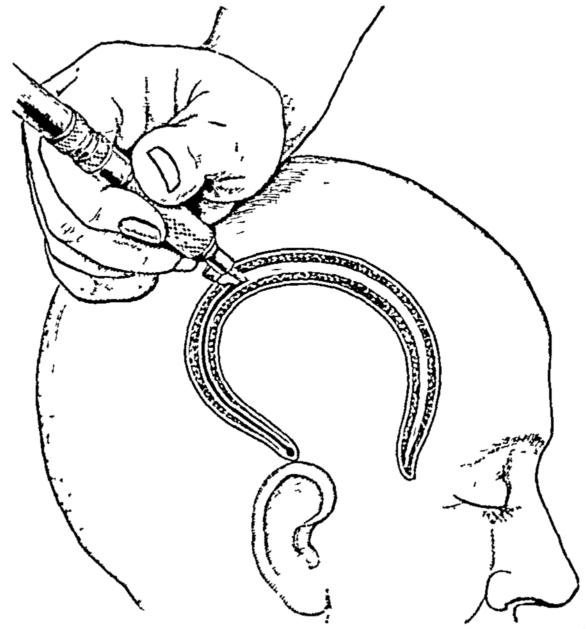

Fig. 2.—Method of removing section of skull with cutting tool, the guard being in close contact with the internal surface, thus preventing injury to meninges.

The engine has also been used extensively in opening into the inferior dental canal or cutting through the ramus of the inferior maxillary bone to reach the inferior dental nerve; also in opening through the superior maxillary bone for resection of the second division of the fifth nerve. Another office which the engine has been called upon to fill is the opening of the brain-case with the absolute certainty of not injuring the brain or its covering membranes.

The cutting portion of the instrument, called a spiral osteotome, is one-half an inch in length, and one-eighth of an inch in diameter, and tapers slightly from base to point. It is divided by three spiral grooves, each having a turn of 120 degrees through the half-inch from the base to the point of the cutting end, the arrangement of its three blades giving it the appearance of a twist-drill. The point of the bur, when in use, is guarded by a button-like attachment connected with the nose of the hand-piece by means of shank and collar. The free end of the bur is doweled into a seat in the guard, in which it revolves, which steadies the whole arrangement when in use, gives an added rigidity to the bur-shank, and holds the bur and guard in permanent relationship to each other.

The principle involved in the instrument described is simply that of a saw arranged to cut in a line with the axis of the shaft of the bur, and not at a right angle to it, as in the circular saw. Such an arrangement allows of cutting in any direction and upon curved lines. This feature is especially valuable in opening the brain-case, inasmuch as fenestra of any desired shape or size may be speedily made.

The mode of opening the brain-case by means of the spiral osteotome is as follows: After division of the soft tissues by the scalpel, a small opening is first made with a trephine mounted in the engine hand-piece; this trephine has a diameter of five-sixteenths of an inch, and is passed completely through both tables of the skull, and the button of bone removed. There is no danger of injuring the dura with the trephine if it be carefully used by one who has had a little training with the instrument upon the cadaver. The opening thus made affords a means of entrance for the osteotome, with its protecting guard, which is next inserted in the opening and the section made along the lines previously determined by running the engine at high speed and forcing the bit laterally in the direction desired. The button-like guard at the point of the osteotome absolutely prevents injury to the dura, which is pressed or dissected away by it from its attachment in the lines of the cut as the instrument progresses.

The instrument as a whole has been designed not only with reference to the mechanical requirements imposed by the dense tissues which are to be operated upon, but with a full recognition of the demands which the later developments of bacterio-pathologic research have made a requirement in all surgical procedures, viz., rigid asepsis of the instruments used.

The hand-piece should be held like a pen, with the third and fourth fingers resting upon and near the parts to be cut, which should also be firmly held. In using the spiral osteotome the third and fourth fingers do not rest on the head. Mechanical guards can be used to prevent the danger of the trephine plunging into the brain; but by holding the instrument properly, one who is accustomed to operations upon the cranium, can, by a little practice, operate with safety without the guard, and even tell by feeling alone what kind of bone-tissue he is cutting, or when nearly through the walls of the skull.

The instrument has been successfully used in making artificial sutures for children. The instrument has been passed between the longitudinal sinus and the bone without injury to the former. The guard will push an artery or vein out of its groove in the bone, but should the artery be enclosed in the canal, as is sometimes the case with the meningeal arteries, the osteotome will cut the vessel.

If, in operating, there are any sharp edges or points of bone left, as is sometimes the case in the removal of the superior maxilla, the finger can detect them and the instrument can be carried in along with the index finger and the roughness cut away. The instrument will not cut the finger unless it becomes caught between it and the bone. Crevices were left by the old-fashioned method of removing the superior maxillary bone and germs of disease had ingress to the parts; but by the use of the engine these rough and deep depressions are avoided, leaving the parts even and smooth[1].

IMPROVEMENT OF BRAIN FUNCTION BY SURGICAL INTERFERENCE.

Presented to the Section on Surgery and Anatomy at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY ERNEST LAPLACE, M.D., LL.D.
PHILADELPHIA, PA.

Only a few years ago the surgeon scarcely dared to invade the sacred domain of the brain. Emboldened by the triumph of aseptic methods in dealing with the surgery of the peritoneal cavity, it followed that the same principles might possibly triumph in the surgery of the meninges and brain. Today accurate results are reached in both, so that sepsis is practically eliminated, and dealings with the brain surgically will depend on intrinsic factors rather than extrinsic for the achievement of practical results. This was the *sine qua non*, without which all reports of results of operations, would be indefinite and unfit to give an adequate idea of the value of a surgical procedure applied to the brain, to achieve or fail in achieving a stated result.

Taking it for granted, therefore, that asepsis has been maintained and considering the subject purely from an intrinsic standpoint, the object of this communication is to develop in a measure the principle of improvement of brain function by a surgical operation.

I insist on this manner of expressing the problem because, in the vast majority of instances, pressure is the cause of this interference, and the relief or restoration of function will depend on our ability to diminish or entirely remove the permanent or transitory compression. Physiology teaches us the delicate arrangement of nerve-cells, their necessity for special function and the intricate blood vessel arrangement on which they depend for proper nourishment. It is foreign to my purpose to discuss or even state the much debated points in the minute anatomy of the texture of the brain. I wish rather to apply to the brain the same hypothesis as to its pathologic reactions, as we have been led by experience to believe respecting other organs of the body.

The title of this paper would, therefore, embody the whole subject of brain therapeutics finding application through surgery. Inasmuch as the handling of this subject in a thorough manner would be far beyond my purpose on this occasion, I must limit myself to: 1. General pathologic conditions as diagnosed. 2. The application to the brain of the same principles of surgical therapeutics, as would have been resorted to to fulfil similar indications in other portions of the body. Two prominent symptoms point to trouble about the brain: 1. Pain. 2. Interference with function. These two symptoms, though generally concomitant, need not necessarily accompany each other, but either one or the other, or both, are always present.

The true explanation is not always possible, but I believe it can be traced to one of the four irritants that form the foundation of pathology, viz: chemic, physical, biologic or mechanical, while interference with function is likewise referable to the same causes.

---

[1] At the conclusion of Dr. Cryer's paper he gave a demonstration of the manipulation of the engine and its tools. Various bones were operated upon and the method of opening the brain case (Fig. 2) for central operations was demonstrated upon a cadaver, showing how an extensive plate of bone may be removed without injury to the dura mater.

Interference with function may be due to a permanent or to a transitory cause. Each of these may or may not be removable. When not removable the cause, though partly attainable, is so disseminated that it involves too extended or parenchymatous a portion of the brain, or else it exists at such vital portions of the brain structure as to forbid the approach of the knife without fatally affecting the true source of vitality—the origin of the pneumogastric and sympathetic nerves. Too much importance has always been placed on what has been called the purely functional disturbances of the brain, such as would correspond to the former idiopathic diseases elsewhere, now being reduced to a strange scarcity under the light of modern pathology. We should push to its utmost the application of the same principles to the delicate neuroglia and complex network of fibers which when unimpaired present brain function as a harmonious whole, and when disturbed even in so little as the faulty crossing or touching of two fibers by any cause, inherited or acquired, produce the same discord in the harmonious whole, as does the crossing of two telephone wires to the intelligent ear at the central office.

Our generation may not see such a delicate lesion as this demonstrated under the microscope, but we already see how gross lesions of the brain centers distinctly affect certain portions of the body. Less is known of the purely ideomotor centers and their disturbances by the same lesions, whether limited or disseminated. Still, proceeding on the hypothesis that the brain tissues, whether in the anterior, middle or posterior areas, are governed by the same pathologic relations as the rest of the body, why not, when sanctioned by a diagnosis based on pathology, proceed in treatment on the same general lines. For the practical application of this principle our technique must necessarily be perfect. We must at first eliminate all failure which is due to faulty technique, and by that is meant death after operation, from *shock*, from hemorrhage or sepsis. This is pardonable in emergency cases, such as traumatisms and tardy cases of mastoid disease when infection exists before the operation. The first requisite, therefore, is that no operator should undertake a brain operation who has not mastered the art of opening the skull, arresting hemorrhage in the scalp, in the dura and substance of the brain without exposing the patient to sepsis. This prerequisite may be styled as begging the question, but I venture to state that this whole question can only begin to be discussed with justice when this point has been reached. While an account of the technique would lead me away from the subject, the one point which I will here lay special stress on is *shock*.

This strange condition following traumatisms, so marked when the brain is concerned, can only be measured by the trained touch of a skilled assistant, the operator himself being forbidden, for reasons of asepsis, feeling the patient's pulse. Better cease an operation without having achieved what we started to do, than expose the patient to death from shock. I consider *that* a part of a faulty technique as I would a subsequent infection of the wound. The rapid and wavering pulse is the index. Hypodermic injections of strychnia (1-60 gr.) should be given from time to time to maintain the pulse at about 100 a minute. Hot water bottles should be constantly kept about the patient, during and after the operation. On being returned to bed the head should be put in a very dependant position, while high enemas of warm water are freely administered. These procedures reduce the possibility of fatal shock to a minimum. If, however, after the administration of $\frac{1}{4}$ to $\frac{1}{2}$ gr. of strychnia, the pulse shows a tendency to rise the operator should be warned and the operation discontinued.

Perhaps the most frequent indications for interference in regard to the brain is after severe traumatisms resulting in concussion or possibly contusion of the brain. We know that aside from the shock attending these cases the congestion of the brain which follows is the prime cause of the interference with function which results in unconsciousness. When these cases recover the ultimate sequelæ are dreaded, that is, epilepsy and insanity. The former when the lateral and posterior lobes of the brain had been injured; the lattea when the anterior lobe of the brain had sustained the injury. Now it would suffice that considerable congestion follow the injury and be maintained for a certain length of time that diapedesis also take place, which resulting in subsequent fibrous tissue, would contract and produce epilepsy or insanity. And this would especially be the case if the patient had inherited or acquired a diathesis. The indication, therefore, is, should unconsciousness maintain itself beyond a few hours, to relieve the congestion as soon as possible by draining the cranial cavity. Should such a contusion have occurred to the soft tissues for instance, we would immediately relieve the condition by local blood-letting, thus removing the tension of the parts. The brain is enclosed in an unyielding fibroserous sac; when the brain enlarges from a traumatism the very swelling is a compressive factor and leads to the special symptoms in the case. Hence, it is my practice to proceed to removing the general compression of the brain by making a transverse craniectomy, removing a strip of skull about one-fourth of an inch wide. The dura mater is then incised the full length of the wound except over the superior longitudinal sinus. The groove is then packed with two narrow strips of sterilized gauze, each one extending from the temporal region to the vertex; the scalp is sutured, leaving the ends of the strips of gauze protruding on each side. This insures perfect drainage without risk of hemorrhage or sepsis. The gauze drain is left eight days *in situ*, during which time the symptoms gradually disappear. At the end of this period the stitches are removed and the gauze withdrawn. This I believe to be the safest and surest way of restoring brain function with the least risk of after-effects, when contusion of the brain resulting in indefinite compression has been diagnosed. The same procedure modified to suit the case is to be resorted to when extra- or intradural hemorrhage exists and the clot being removed and the hemorrhage stopped, the case is then transformed into one similar to the above. During the last four years I have treated twenty-wo cases in this manner, with a uniformly good result. A young one-arm man riding a bicycle fell upon his head and being totally unconscious, having remained so during two days, was treated as above described and rapidly recovered consciousness after the operation. During the first days of the treatment the dressings were constantly saturated with serum and cerebrospinal fluid. The same uniformly good results were obtained in a number of other cases of concussion treated according to this method.

Inasmuch as acute meningitis is accompanied by intense congestion of the brain, resulting in compression as manifested by delirium and spasmodic twitchings, I resorted to drainage of the cranial cavity in one case and obtained a favorable result.

Finally, I would recommend actual local brain drainage whenever the evidences of brain compression by congestion can not be speedily relieved by the ordinary measures of drastic purgatives, blood-letting, etc. In forms of chronic inflammation of the brain due to specific disease where the symptoms point to a gumma resulting in compression, the exact location of which can be ascertained, an operation is indicated for removal of the gumma. There are, on the other hand, many cases of brain disease directly associated with syphilis, and which persistently refuse to improve under the specific treatment. They manifest themselves in mental hebetude and paresis. I have had the opportunity of treating five such cases. In each, being assured of the presence of syphilis, and having ascertained that the patient had had the full benefit of mercurial treatment, I did the anterior craniectomy, separated the adhesions which had formed between the dura and skull, opened the dura, packed and closed the wound. Two days after the operation the patient was placed on the specific treatment and the symptoms disappeared. I wish, therefore, to draw special attention to the principle in brain therapeutics, by which drugs produce an alterative effect after an operation, having proved without action before the operation. I have no scientific reason by which to explain this phenomenon except the analogy which we find in the use of massage for breaking up inflammatory exudates, and resulting in a better action of iodids and other alteratives than they would exert without the massage. I believe we all have had this experience in treating joints, etc., and I find that the same principle is applicable, to a certain extent at least, in the brain.

Another principle, so extensively applied elsewhere in the body and so little understood, is that of counter-irritation. There is no doubt that the phenomenon exists empirically, and that an inflammatory condition will be diminished and sometimes arrested by another strong irritation being excited in the neighborhood. The same principle may be applied to the brain, and especially in such cases of alteration in brain function as exists without definite causes, and are still called idiopathic. Under this heading can be classed many cases of epilepsy and insanity. It is my conviction that none are absolutely idiopathic, and that when progressive the cause is not latent but one which rests on already known pathologic conditions.

The mere traumatism incident to incising the scalp, trephining, and irritating the dura over the region of impaired function, may at times suffice to alter or arrest by counter-irritation, the original pathologic process and be followed by improvement. We have thus treated fifteen cases of epilepsy, without marked focal lesion. In six cases the improvement manifested itself by a marked diminution in the number of epileptic attacks. In the other cases no apparent improvement in the number of attacks followed. In all cases, however, the patient gave evidence of improved mental condition, that is, clearer understanding and a better memory. In no case was the patient worse after the operation.

In four cases of insanity with a history of an injury to the anterior portion of the head, the anterior craniectomy was performed, a large number of adhesions of the dura to the skull were separated and soon afterward the cases recovered and are still in good condition.

This treatment has also been applied to numerous cases of microcephalus and arrested development of the brain. In cases of idiocy due to microcephalus, I have done three craniotomies for the reproduction of the sutures of the skull. At the first operation the coronal suture, at the second the sagittal, and at the third the lambdoidal suture was made. These operations were performed at three months' interval. The object is to reproduce as much as possible the same sutures which the soft bones of the child possessed at birth. The improvement following in these cases has not been uniform by any means. Some cases have shown marked improvement both in mental and physical results. The mortality was 2 per cent. No case was made worse by the operation. The direct lesson to be gathered is that these imperfectly formed brains surely took a greater amount of nourishment, and improved in function after the surgical interference.

There is another class of cases that might be called tardy or arrested development of the brain. The children reach the age of 10 years and are unable to talk, and do not possess the intelligence which would belong to a normal child of 4 or 5 years of age. The head seems to be of normal size. This class benefits most from extensive craniotomies and opening the dura mater. An improvement seems to begin very soon, the agitation of the limbs and the shrieks quiet down considerably. The function of the intellectual centers seems to especially improve. Within a month these children have learned to count and to speak sentences before unknown to them. If heretofore we have not had as flattering results as we anticipated, it may be from the fact that the operations performed were not sufficiently extensive, or else were not performed on the intellectual area. Our operation consists in trephining over the temporal fossa and removing a strip of skull over the coronal fissure about one quarter of an inch wide and directly across the vault to the opposite temporal fossa, then opening the dura throughout except over the longitudinal sinus. This certainly creates an impression on the brain during which it is nourished into better function. Whatever may be the criticism of this mode of procedure the results speak for themselves. We do not claim anything except altering the nourishment of the brain in these patients, and rendering them able to appreciate and retain impressions more easily than without the operation. In other words, this procedure is in no way opposed to or intended to do away with the training which these children get in schools for the feebleminded. On the contrary, the purpose is to put to the greatest usefulness, such brain capacity as is there, so that the children may improve and benefit by the training at school, to a greater extent than if no surgical interference had awakened their limited intelligence to its fullest capacity.

DISCUSSION ON PAPERS OF DRS. CRYER AND LAPLACE.

Dr. Hal. C. Wyman of Detroit, Mich.—I believe the ideas advanced by Dr. Laplace are with us to stay. It is very important that this department of surgery should receive the endorsement of the surgical profession. No more rational means are necessary in connection with these surgical principles than those which apply to inflammatory diseases in other parts of the body, especially drainage, and without drainage many cases die. The results of operations at the hands of those who are advanced in this respect are that some of these cases get well. All cases are improved by surgical treatment. With regard to the apparatus just demonstrated, I would like to ask the operator how that device works on the living subject. I realize that there is need of some more rapid method of removing portions of the skull. I have tried some machines and invented some. All of my own have been failures when used upon the living tissues. The blood flowed and the life-like properties of the parts seemed to choke up the parts of the saw so that it would have no cutting power. I do not wish to condemn this apparatus. It is a simple mechanical method and works well in the cutting of dead bone, but this is very different from the living. If this saw works well on the living subject it is certainly a great advantage, especially if the blood and bone dust do not block it up.

Dr. I. N. Quimby—I would like to refer to one case of a sea captain who was injured by a fall in which he was struck upon the ear. During the operation he was taken suddenly into a comatose condition and the wound closed up. I gave him an active cathartic and drained the wound with some relief, and later I reopened the wound and established good drainage. He was much improved for several weeks and the comatose condition passed away. I allowed the wound to heal and there has been no trouble since, which was three years ago. I found upon opening the skull that there had been little superficial tissue formed. This case was a capital illustration of the benefit of drainage.

Dr. J. D. Thomas of Pennsylvania—I refer briefly to three cases of trephining. The first was that of a young man who had been struck on the right side of the head with a club. One week afterward, after suffering considerably, I found him unconscious and completely paralyzed. There was a scalp wound on the right side and I trephined, but found no fracture of either plane. Owing to what seemed to be a very acute condition on the parietal eminence, I penetrated the membranes with considerable hemorrhage. I let the blood run for awhile and then stopped it with hot water and dressed it with antiseptic precautions. Three hours afterward the young man spoke and finally recovered. He is living today and has had no return of his symptoms. The second case was that of a boy 14 years of age who had fallen thirty-five feet, his head striking some timber. The skull was broken all over, so the attending physician told me, but I could find no depression. I was called ten days afterward, when the boy had convulsions continuously on the left side. I thought I discovered something on the right side and trephined. After the operation he had only one mild convulsion and fully recovered. The third case was that of a man who was driving a horse which ran away, throwing him out of the wagon, fracturing his skull extensively just above the ear. I trephined and removed a two-inch fragment and the man made a complete recovery. The important point is that there was no fracture in my first two cases. The hem- [illegible] was quite extensive, however. There was recovery in [illegible] the cases.

Dr. Miles F. Porter of Indiana—The most important and [illegible]-reaching point in Dr. Laplace's paper is the idea that underlies the whole subject. To relieve the compression, both inflammatory and non-inflammatory, is a most important point and it is an entirely new theory in so far as it applies to the matter of nutrition. It is also new to me as applied to such cases as the Doctor speaks of, wherein there is no hemorrhage, either extradural or intradural. The fundamental principle seems to be the relief of the compression. As to the instrument, I whould like to know how hot the machine gets.

Dr. Allen DeVilbiss of Toledo, Ohio—I agree with the remarks of the other speakers and believe that Dr. Cryer's instrument works well. I read a paper once in which I argued in favor of a speed of not over 2,000 being sufficient. I was then using a saw. I had quite an experience with it. It was so made that the drill would stop so soon as it got through, for the reason that force and resistance ceased. There are two reasons why I discarded my saw. The first was that the frictional heat produced death to live bone. The heat seems to penetrate the same as ice will penetrate, and in order to use the instrument we must keep it cool. Ten thousand revolutions is very high, although it may be necessary. The second reason was that the under jaw is so constructed that it shelves the dura out of the operative field. If Dr. Cryer had been operating on a living subject he would probably have avoided the artery. I now use the chisel because it lets me know when I am through. Dr. Beck has made an instrument three inches in length for brain operations, by which he can open the skull in seven minutes. I improved the operation some three years ago and took out three inches over the fissure of Rolando, the piece being two inches wide. My instrument could be taken apart and packed in a very small space. I spent $10,000 for the development of that saw and was very loathe to give it up. This instrument in the hands of a better surgeon than I would be a failure simply because he was not familiar with it. I have now discarded it altogether. Three years ago one of the members of the staff of the hospital with which I am connected, used the identical engine that is used today on the living subject. The trouble we then experienced was that when the button of bone was removed and the bur introduced at the angle it would work but a little distance before it was clogged, causing great delay. All of these complicated machines do not pan out well under any circumstances. They have been such a failure in our hospital that we have given them up entirely.

Dr. J. William White of Philadelphia—I have not been as fortunate as Dr. Laplace in my results nor in the smallness of the mortality. I am very distinctly of the opinion that the mortality of all operations involving the opening of the skull is above 2 per cent. Taking all cases together we can not promise that the risk is so slight that only two out of a hundred die. We should make a clear distinction between the forms of infective brain disease and those discussed by Dr. Laplace. Drainage has saved many lives, but the indications for it are by no means so clear in non-infective cases. It seems to me to be an open question whether drainage is employed in all cases in which Dr. Laplace has referred to. When opening the brain you are apt to have multiple minute hemorrhages which can not possibly be drained through any given series of openings. I think we must recognize a considerable mortality in the beginning. We must not confuse drainage in infective cases with those cases which Dr. Laplace has been describing. We must make every possible allowance for the ease with which the family of the patient and the surgeon himself may be deceived. We are all naturally anxious to see good results follow and the parents are even more anxious. It requires many cases and many observations before it would be safe to say that improvement should be expected under such circumstances. The effect of any operation on some of the cases described by Dr. Laplace should be remembered. Some years ago, about the time that antisepsis was introduced, Dr. Agnew and I had many cases of epilepsy, some of them supposed to be traumatic. We did exploratory trephining and in a large percentage of the cases nothing was found to account for the epilepsy. There were histories of falls, injuries, etc., but on exploring the suspected region we found nothing abnormal. In every case there was some improvement in the epileptic condition and the convulsions either disappeared or lessened. I was led to make a number of series of investigations, and I gathered all the cases together that I heard of and included them. I was surprised to find what a large number of cases have been recorded in which the sugeon has been disappointed or has found something which he believes to be curable. The mere opening of the cranium and the handling of the parts has been followed by a disappearance of the symptoms, but these cures are only apparent. We, no doubt, do some good that we can not ourselves understand, and there is just as little doubt that what we do can not be regarded as scientific. I think this must be considered in estimating the alleged improvement after operations, and I believe that the improvement will be found less great than Dr. Laplace would lead us to expect. The mortality will be greater, the improvements will be confined to a much smaller class of cases and will be temporary and unsatisfactory. I think this most important question should be thoroughly considered before we recommend to patients in these conditions general operative procedure that is supposed to apply to a large majority of these cases. The cases in which there are localizing symptoms I do not criticise. In any method of surgical infection of the brain we can readily resort to drainage and so in insanity. In all cases of operation, if the surgeon believes there is a particular spot of infection he should open and drain. In McKean's case he had mind-blindness and could not understand what he saw. This led to the diagnosis of some trouble about the angular gyrus, and a depression was found at that point. That is rational surgery. I want to enter my protest against the general belief that the cases referred to by Dr. Laplace can be operated on with the small mortality that he would have us believe.

Dr. Lewis A. Sayre of New York—Gault's mechanical trephine is the most practical and it can be used without the possibility of danger to the tissue or to the dura. His trephine is the best I have ever seen. It had a spiral movement to it, and when the instrument got beyond the bone it would stop. I remember the case of a man 35 years of age who had worked himself under a bookcase and we could not get him out. Finally he was extricated and brought to the Bellevue Hospital, where I examined him and found a tender spot over the lateral sinus. Upon touching this he would begin to shake. I brought him before the class and sent for Gault to trephine him. I expected to find exostoses afterward, but there was none nor any pressure symptoms, and the man has never had a fit since.

Dr. Laplace—I am glad that one speaker found serious objection to my paper and especially as to the mortality. I hope no one misunderstood me. Two per cent. mortality is based upon giving surgery a show. My only object has been to put the matter in a clear light before the profession. Later it will be shown whether children are able to withstand a certain amount of shock. As I explained in my paper, I tried to stay on this side of the line of reason. When I find an operation too grave I stop there and, acting on this fact, I wish to say that there is no earthly reason why the mortality should be more than 2 per cent. If there is, it is the fault of the surgeon. As to drainage, let me say that, granted there is a certain amount of contusion, there is autocompression of that brain and opening the dura will necessarily relieve it. I think you will all agree with me in this, that when the dura is opened the cerebral fluid spurts out. In these cases the patient will become conscious in a few hours. I do believe that such an extensive craniectomy, accompanied by an incision into the dura, will relieve to a certain extent the whole of the brain, but more especially the anterior portion, as it is generally in these cases that unconsciousness exists. As to cases of arrested development, I thought I made my position clear. I admitted that the operation was impractical, and I do it because I hope to have some consultation on the theory of counter irritation. Dr. White knows that there are cases in which improvement follows and we know not why. Why may this not be one of those classes? We all know how in cases of abdominal surgery today there is no hesitation in exploring the cavity, and if things are all right it is closed up, but if not all the conditions present are attended to. I am glad that one man spoke in the way he did. We must be very careful in doing this work, but we should not be backward. We know all about hemostats and antisepsis, and we can adopt both if we need them. Finally, in trephining over temporal fossa I go through the thickness of the skull, but not through the inner table if I can help it, as I prefer to break this off with the chisel. The middle meningeal artery runs through the skull in many places and, therefore, it is unwise to trephine directly through the whole thickness of the skull. I have an instrument with which I separate the adhesions and it is particularly useful for this purpose over the longitudinal sinus. I run this instrument all over the surface of the dura and pass it all around the opening, completely separating the adhesions. The instrument is no larger than an ordinary wire, and it has the advantage of not tearing the tissue at any time. Beginning at the superior longitudinal sinus I plunge my knife directly down the surface of the brain, and you would be surprised to find how the cerebral fluid comes out. There is no danger of hernia, as the opening is not large enough for the brain to protrude. I use T-forceps for this special purpose, and not more than one ounce of blood is lost. I proceed to pack, after having opened the dura, with fresh sterilized gauze. Ordinarily I do not use iodoform gauze in the brain, but under some circumstances it does very well. Some brains have a strange idiosyncrasy against iodoform and it will start up an irritation there which will be very prone to become septic. I therefore simply use dried gauze sterilized, and I apply two pieces to drain, packing them well into the groove I have made. I gradually remove the forceps and apply my sutures. There is no shock, and practically no loss of blood, although some of you might be disposed to doubt that. When I first began to operate I did not do it in the way I do now and I did not succeed in my early operations as I do now. We must not consider these operations lightly by any means, and we must not operate on the brain promiscuously. All cases that are operable should be operated on by those who know how to operate, and there is practically no difficulty in removing the cause.

Dr. Cryer—Dr. Wyman questions how the instruments operated by the engine will work upon living bone. It works quite as well upon living as upon dead bone; the tools do not become clogged or choked, nor do they become heated, provided the cutting tools used are made especially for the type of bone to be operated upon. Heretofore the cutting tools were made without sufficient regard to this particular; as a rule they had too many blades which were of equal size. You will observe these tools have three blades differing slightly in size; this prevents chattering or vibration of the tool, and they are self-cleansing. The subject which I have used for demonstration has been dead but three days, and the texture of the bones is almost the same as in the living subject; to be sure there is no blood flow, but the cutting under blood interferes with operations only in so far as it obscures the view of the territory.

ACUTE PARTIAL ENTEROCELE.

Presented to the Section on Surgery and Anatomy, at the Forty-eighth Annual Meeting of the American Medical Association at Philadelphia, Pa., June 1-4, 1897.

BY FRANK A. STAHL, M.D.
DEMONSTRATOR OF OBSTETRICS, RUSH MEDICAL COLLEGE; EX-INTERNE ROYAL FRAUENKLINIK, MUNICH.
CHICAGO.

Herniæ involving only a portion of the circumference of the bowel, and usually spoken of as Littre's herniæ, are of two forms: One is a diverticular hernia, a hernia where a diverticulum of the bowel forms the contents of the hernial sac; the other is the partial intestinal wall hernia, partial, lateral enterocele (*enterocele partialis seu lateralis seu hemiperipherica*), where only a segment of the free margin of the bowel forms the contents of the hernial sac. Partial intestinal wall herniæ occur in two forms: The acute partial enterocele, where the hernia is of sudden origin and without adhesions; the chronic partial enterocele, where the hernia is of slow origin and usually with adhesions; that the acute form occurs is denied. Clinical experience alone can refute this denial, and the material is not lacking that will constitute the necessary burden of proof to establish the fact that acute partial enterocele occurs; it is in this spirit that the writer has been led to present the following clinical manifestations.

In 1891 I reported a case of acute partial intestinal wall hernia occurring in the sac of a previously existing incomplete inguinal hernia.

The peculiar symptoms in this case were: 1. Absence of any tumor, slight redness of skin over point of rupture. 2. Pain commencing at and returning to a point marking the place of exit of previous hernia. 3. Patient had two loose stools, which caused increase of pain at the seat of stricture. 4. Continued retching, but no vomiting. 5. Just before surgical anesthesia was reached in attempting to reduce by taxis I was able to appreciate a sensation like that of drawing upon something immediately above the seat of previous hernia, having a fixed extremity and which, as the anesthesia became more profound and traction was continued, gave way little by little. Traction being further continued a slipping like that of this something being suddenly released was experienced.

Case 1.[1]—A record of the case is as follows: Male, 28 years of age, weight 145 pounds, height five feet seven inches, nervous temperament, wood-turner by trade, required to stand most of the time; no record of abdominal traumatism previous to primary occurrence of a year ago, when I was sent for and found a strangulated incomplete inguinal hernia of the right side, which was soon reduced after using hot fomentations and taxis. Truss applied; continued his work the next day. Patient went to work in the morning feeling as well as usual, the truss retaining the gut. During the morning he did some lifting. Soon after the lifting he noticed, while standing at his bench, a slight pain at the place of rupture. The pain continuing, he examined the part, but could find no tumor, so thought nothing more of it, and continued his work. As morning wore on, noticed that the longer he worked the more intense became the pains, bowels moved once during the morning. During dinner-hour, getting an opportunity to lie down he did so, the pains relaxing somewhat, not wholly. Soon after commencing work the pains reappeared with increased severity, but now taking on a different nature. His bowels rolling, commencing at the point of rupture, continuing to the pit of the stomach, returning again to the starting point. Bowels moved (loose stool) again during the afternoon with slight momentary exacerbation of pain at the point of seizure. Notwithstanding the intense nature of the pain he continued working, finished with the others and made his way home, walking part of the way. Arriving there he complained of dizziness from the pain and exertion, still he did not lose consciousness. Thinking that if he would lie down awhile the cramps would cease he went to bed. His condition not improving, rather continuing to grow worse, word was sent me.

Examination found the patient lying on his side with limbs fully flexed, hands holding abdomen; face presented that anxious, pinched expression peculiar to peritoneal trouble; skin hot covered with perspiration; respiration and pulse slightly increased; continued retching but no vomiting present; no tumor at point of rupture; skin covering it slightly reddened. Pains were of sharp lancinating character, commencing at the point of rupture and extending to the pit of the stomach. Patient showed tenderness at only these two points. Percussion showed marked meteorismus. Recalling my experience with previous hernia I immediately thought of a strangulated hernia of a small part of the circumference of the bowel; still the probability of a peritonitis also presented itself. Applied hot fomentations, and administered morphin per stomach, one grain in divided doses within half an hour. Instead of affording relief, the pains continued to grow, so ruled out the peritonitis and adhered to my first impression of strangulated partial hernia. The wife, as on a previous occasion, requested me not to operate unless absolutely necessary, so I administered chloroform, preparatory to trying taxis. With one hand below the point of rupture, the other above, I, alternately pushed with the one hand, made downward and upward pressure with the other upon the abdominal walls with contents beneath. The latter movement produces traction. Continuing the traction, I was able to appreciate the sensation as of drawing upon something beneath my fingers and within the cavity whose other end was fixed. The narcosis becoming more profound I continued to make traction, and was soon to my delight rewarded with a sudden slipping upward of the hand making traction, consequent upon the extremity of this something being suddenly released.

As mentioned above I had already administered a grain of morphin before giving the chloroform. Before the reduction, if the chloroform was not pushed, the patient soon rallied. After the reduction, though the chloroform was immediately removed, patient did not rally but continued sleeping, his face now presenting a less pinched appearance, his respiration becoming slower, also his pulse. Remaining yet a little while, noticing his improved condition continuing, I left, leaving instructions to let him continue sleeping.

Directed to take a bottle of citrate of magnesium and teaspoonful of mixture containing ¼ grain of morphin every four hours and soft diet. . Next morning patient was up and about. When having a movement of the bowels the next morning, after taking citrate of magnesium, and also an enema, pain was caused in the region of the cecum only, the patient expressing himself as follows: ' My bowels pain me in one spot only while I am having a passage, otherwise I have no pain." Truss was applied and the third day after occurrence patient was able to return to work.

In the discussion several expressions of doubt found utterance as to the correctness of the diagnosis, one thinking the case had been one of omental hernia; another thought the case one of simple invagination of the bowel. The history of an acute epiploitis arising from an acute hernia differs very materially from the above. Professor N. Senn, in the course of his remarks said: "A Littre hernia is a hernia that is exceedingly dangerous. It is a hernia that contains only a part of the circumference of the bowel. The hernial ring being very small and the contents of the hernial sac being limited, gangrene takes place in a very short time. I hardly think that by ordinary care it would be possible to confuse invagination with Littre's hernia, because in Littre's hernia at least a slight external swelling can be detected, the swelling occupying a position where we expect to find the different herniæ. The writer has informed us that in the last case he suspected that the Littre hernia followed as a secondary condition of a former well marked hernia, and therefore I have no doubt that it may have been a Littre hernia which was reduced before signs of strangulation occurred."

At the time I reported my case I had not met with Lorenz, "Ueber die Darmwandbrüche,"[2] else I might have presented another case very similar to mine in many respects (though more severe in degree), both in the history of the anamnesis, symptoms and signs, and in the anatomic relation of the parts involved.

The case presented itself for operation in Professor Albert's clinic. From the previous history of the case, it seemed like mine, one where secondarily an acute incarceration of a segment of the bowel with strangulation was manifesting itself, in a previously existing hernial sac.

That such a phenomenon could occur had been up to this time (1883) a mooted question. Therefore, in performing the operation it was done with this special problem in mind: Do acute intestinal hernia occur into a previously existing hernial sac or, in other words, can an intestinal wall segment suddenly enter a congenital, or a more or less longer existing hernial sac and immediately become incarcerated.

The findings of the case under operation were such that Lorenz presented a history of it, showing and to prove, that a bowel segment can and does become so incarcerated.

Case 2.[2]—A well developed boy, 16 years of age, slight in figure and healthy appearance, when seven years of age (1874) was directed to wear a truss for a right inguinal hernia. He continued to wear the truss for several years. In the course of time, the truss becoming too small, he laid it aside until the present occurrence, September 1883, without complaining of any discomfort. Sept. 11, 1883, while he was carrying wood, he was suddenly taken with abdominal pains and vomited twice in succession. Immediately palpating the addominal walls the boy discovered a small tumor in the right inguinal region. Vomiting continued during the night. September 12, boy feels comparatively well. After unsuccessful attempts being made, by a physician, to reduce the hernia, the patient entered the clinic that evening. With the exception of an active thirst the patient presents no other symptoms. After drinking immoderate quantities of water he vomited once toward evening and once during the following night. An attempt at stool was almost without result.

September 13. With the exception of drawing pains in the abdomen patient feels well. Flatulency, none since the critical evening, the facial expression is normal; the pulse full and strong; continuous thirst. Abdomen flat, very slightly sensitive to palpation. In the right hypogastrium upon deep and brusque palpation sensation slightly greater, but there is not the least resemblance to the intense pain usual at the neck in hernial strangulation.

Operation: Cutting down, opened sac from which there flowed, proportionately speaking, a large quantity of a hemorrhagic colored fluid. The whole tumor seemed to melt away entirely; found a blue, red appearing, swollen part of the intestine; no trace of omentum; no adhesions between bowel wall and hernial sac. Because of the small size of the bowel segment the possibility of a partial enterocele presented itself, and to determine the question the greatest care possible was exercised in the further dissection of the parts. At the internal inguinal ring a conical portion of the intestinal wall was found incarcerated; the structure was divided and a considerable portion of the intestine drawn out to demonstrate that the mesenteric border of the gut presented absolutely no changes upon its superficies, and was of normal red color, while upon its convex border there appeared the well marked strangulation furrow, that loosely encircled a protruding intestinal wall segment. The gut was replaced; wound dressed to favor union by granulation: toward evening much flatulency. The night was passed without pain and sleeping most of the time.

September 14. Wound dressed; looking well; abdomen soft and painless; flatulency continues. General condition good.

September 15 and 16. In the night two bowel movements, profuse and soft. Condition continues good. Recovery followed without anything of note occurring.

Again there are exceptional cases where the symptoms and signs point to incarceration with strangulation, yet herniotomy determines only an empty hernial sac with subsequent cessation of symptoms. Here it would seem that a small segment of the bowel had been incarcerated, strangulation with its manifestations following; primary attempts at reduction with taxis are made; they fail; the anesthetic is hurried;

the narcosis may induce relaxation of the spasmodically contracted hernial orifice; reduction may succeed as in my first case (1891), or this happy result may not be induced until herniotomy with opening of the sac occurs, and then only to find no intestine. In this latter case undoubtedly at some time during the narcosis or herniotomy there was relaxation of the spasmodically contracted hernial orifice sufficient to release its grip upon the segment of the bowel wall; the bowel would then retract within the abdominal cavity.

In dwelling upon this feature of this form of hernia Lorenz mentioned such a case where operation was necessary, that developed only a hernial sac but no intestine.

Case 3.[2]—Moderately well developed but strong woman. Four months ago she noticed a small prominence in the left groin, upon the advice of a friend, wore an improperly fitting truss, which she soon laid aside. September 11, in an argument with a friend, she received a kick in the region of the lower abdomen. From this moment she complained of strong abdominal pains and repaired to the *Polizeiartz*. He rendered a negative opinion and quieted the woman, who, notwithstanding, took to bed. During the night she experienced heartburn, belching, retching and profuse vomiting three times. The patient discovered a nut sized elastic tumor in the left groin. Calling upon the *Bezirksartz*, he diagnosed a hernia and advised immediate removal to the hospital. During the night of September 12 and 13 patient applied cold compresses, and during this time was disturbed by continuous belching and retching. Passed restless night, appetite lost. As her condition did not improve she permitted herself to be taken to the hospital where for four hours she was closely observed. During this time there was continuous retching, yet no vomiting. No flatulency for three days, and though, to ease her condition, patient repeatedly attempted to stool, her efforts remained unsuccessful. At the time of her admission patient presented the appearance of one seriously sick, complaining of great weakness and abdominal pains, true collapse not present. In the left groin, a pigeon-egg sized, firm, hollow, percussionable tumor, covered with normal integument, which accurately indicates a left femoral hernia. Abdomen moderately tympanitic and excessively sensitive. Palpating the hernia and sac, patient contracts because of intense pain. Attempts at taxis in warm bath without result. Patient narcotized, taxis repeated unsuccessfully; herniotomy.

After careful division and drawing apart of the hernial sac there was nothing to be seen of an intestinum. It is impossible to advance the tip of little finger in the direction of the femoral ring. After repeated attempts, a strong sound was introduced several inches in the direction of the abdominal cavity. The sound completely obstructed the unusually small hernial sac; therefore, the presence of an incarceration was ruled out. Sac extirpated, tied, wound closed, continuous with the narcosis, patient fell into a sleep and awoke late in the evening without abdominal pain and retching. The next day flatulency. Not until the third day did the bowels move and then profusely following two clysmata. Wound healed with first intention. On the second day appetite reappeared and patient considered as convalescent.

In regard to this case, taking into account that when the hernial sac was opened there appeared but a transparent clear serous fluid and that there existed a three-days impermeability of the bowels, the probability must be thought of that through the narrow hernial orifice a bowel segment had been invaginated, which, however, had withdrawn itself even before the operation. Lorenz does not even attempt to question that the invaginated intestinal segment can withdraw itself again.

Unless relieved, what happens in such a case of neglected incarceration of an acute partial enterocele?

1. Symptoms of strangulation follow, with inflammatory changes. If the inflammatory processes be too active for the powers of the general system, then follow gangrene, sloughing, perforation, artificial anus, exhaustion and death, in rapid succession. While preparing this paper Dr. Robinson informed me of such a case having occurred just recently in the hands of a country practitioner. "The tissues were incised down to the gut, which was left to slough. A segment of the bowel wall, directly opposite to its mesenteric attachment, was caught in the hernial ring. At first gas passed from it for several days. On the fifth day after the first incision a laparotomy and a bowel resection with a Murphy button, was performed. Death resulted from sepsis."

2. The system countenancing the reactionary processes induced by the incarceration, strangulation does not occur, adhesions set in and the acute condition gradually merges into one of chronic partial enterocele. Like changes may and do occur in old herniæ; a spot inflames and becomes adherent, and though at times the greater mass of bowel spontaneously returns within the abdominal cavity, a small segment of the wall still remains hernial, bound down by its adhesions. Since the bowel lumen is only slightly disturbed, the feces pass with little or no trouble, the general system soon adapts itself to the new condition of things and exists an indefinite length of time in this state until an acute exacerbation compels relief or ushers in death.

Such was the history of my second case, which is quite typical of these cases of chronic partial enterocele.

In August 1896, I was called to see a woman, aged 60 years, who had already been confined to bed some ten days before I saw her. She was of medium development, fairly strong, but tissues quite flabby. There was no history of previous hernia. Four years ago she suddenly noticed a small swelling in the right groin. She did not know how long it had been there as its appearance was not the result of any known cause; neither was it marked by any of the symptoms usual in acute hernia. The swelling would disappear and reappear, seldom producing any protracted serious discomfort, more than that of a day or several days at the most. At these times she would complain of pain at the site of the swelling, and anorexia and constipation. This was attributed to exertion, catching cold, with colicky pains and acute constipation, for which her physician advised rest, and administered, among other therapeutics, much of a cathartic nature. Hernia was thought of, but because of small size and transitory appearance of the swelling his opinion inclined to a glandular swelling with occasional inflammatory reaction.

Some ten days ago, while beating carpets, in lifting a piece over the line, patient was suddenly seized with a sharp pain at the site of the swelling; palpating the parts noticed, the swelling had increased in size and was now tender to the touch, and she went to bed. Reflex symptoms, as belching, retching and colicky pains, soon manifested themselves. Her attending physician administered a medical acute intestinal obstruction treatment, with opiates for pain, lime water, etc., for vomiting, and various cathartics with repeated clysmata for the non-bowel movement. For some days no attention had been shown the swelling. When attention was called to the swelling from the inflammatory picture it presented, a probable suppuration of an inguinal gland was thought of, complicating the acute obstruction. Poultices were ordered applied. Her family physician calling in a friend, the consultation determined in the order of their importance, a suppuration of a gland, a possible perinephritic abscess and a possible gangrenous hernia, with indications for immediate operation. The next day, being invited to see the case, examination revealed a reddened, inflamed, firm oblong mass along and over the right Poupart's ligament, and continuing down into the right labium.

Palpation.—Tenderness which spreads out toward and over cecal region, superficial and deep fluctuation with crepitation, as though there was gas in the tissues.

Percussion.—Over swelling gave suppressed, deep sounding hollow note. Abdomen sensitive only as the region close to the suppurating mass was approached; tympanitis not marked. General symptoms, expression, etc., were indicative of a local peritonitis with gangrene from hernia. For a week no bowel movements, anorexia, retching, vomiting and slight increase of pulse and temperature.

My diagnosis was strangulation of an acute exacerbation of a chronic partial enterocele at the right femoral ring with gangrene, perforation and septic perforating cellulitis.

Cutting down upon the mass a profuse ichorous discharge was liberated, in which was noticed pus, necrosed tissue, gases and feces. Many pocket-like sacs were opened up in the surrounding areolar tissue, containing a like ichorous material. With continued irrigation the field was finally cleared of ichor, feces and débris. Deep down and above in the femoral canal I found a gangrenous bowel with perforation, through which at first passed much gas and some feces. Simultaneously the slight abdominal tympanites disappeared. Upon one side the bowel was bound down by adhesions, upon the other side it was free, and careful examination seemed to show that there was only a part of the circumference of the bowel at that point in the hernial ring.

I confined my examination to inspection only, as I thought it better to wait forty-eight hours before resecting the bowel, in order that in that time the bowels might have opportunity to thoroughly empty themselves and the inflammatory reaction abate. The wound was dressed with absorbent cotton.

Patient reacted beautifully, citrate of magnesium [illegible] was administered. During the night, late, the [illegible] bowel moved repeatedly and profusely through the artificial anus; there were also two movements through the natural anus. I attributed these two movements to the inflammatory reaction caused by the operation, and due to which there must have been a strong intestinal secretion throughout, causing two loose movements. These must have been from the more lower bowel, as two days afterward the rectum was again found full of dry scybalæ.

Frequent dressings were given during the forty-eight hours. The wound looked clean and healthy, and the symptoms abated very materially. The lower bowels were emptied, so far as possible, by means of clysmata. Secondary operation was performed for resection of the bowel and closure of artificial anus. The adhesions were broken down with the tip of the finger, the bowel drawn out and resection performed. I did not use a Murphy button, fearing its non-passage through the lower partially collapsed bowel; bowels returned, wound dressed; no shock, no collapse. Next day she conversed, with smiling face. Two days after operation the patient died. There were little symptoms of peritonitis present, her pains were very slight considering the operation and that no opiates were used, and death seemed due to gradual exhaustion.

Through the kindness of Dr. Geo. H. Weaver of the Pathologic Institute of Rush Medical College, a report of the findings in the specimen is as follows:

The specimen consists of a portion of small intestine, about 5 cm. long on either side of a defect in the wall. The upper portion is 3 cm. in diameter, the lower 1.5 cm. The wall of the upper portion is thicker than that of the lower. On the free border of the intestine near the middle of the section is a conical projection 2.5 cm. in height and 2 cm. in diameter at its base.

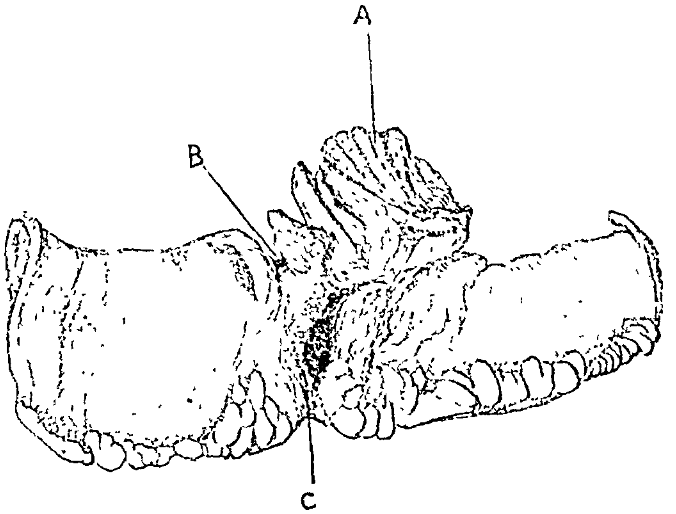

Fig. 1.—Resection from a case of chronic partial enterocele—chronic Littre's hernia—with acute exacerbation, showing: a, acquired diverticulum: b, acute exacerbation of hernia; c, gangrene with perforation.

The outer surface of the projection is uneven from the presence of dense fibrous bands and masses. About its base on its outer aspect is a circular groove fairly well defined. The serosa of the intestine is continuous with the outer surface of the projection. This projection is located to the lower side of the point of gangrene in the intestinal wall, to be described below.

On section through the cone, from apex to base, its walls are seen to be continuous with those of the intestine and to be made up of a fibrous layer externally continuous with the intestinal serosa (Fig. 2, C), a muscular layer (Fig. 2, B) continuous with the intestinal musculosa, and an internal coat continuous with the mucosa of the intestine (Fig. 2, A). The projection internally is occupied by a cavity opening into the lumen of the intestine.

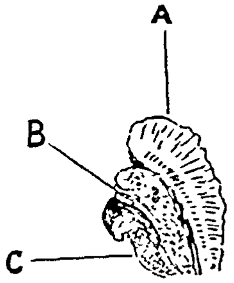

Fig. 2.—Section of the diverticulum from apex to base, showing the intestinal layers: a, mucosa; b, musculosa; c, serosa.

Microscopic examination of a section of the wall of the projection shows that all the coats of the intestine are continued across its whole height, muscular and mucous coats being present.

The wall of the intestine is defective from a gangrenous process on one side just above the projection above described (Fig. 1, C). At both ends of the gangrenous defect are well-marked grooves in the outer aspect of the intestine, both at the free border and at the mesenteric attachment, running at about right angles to the lumen (Fig. 1, B). This evidently indicates the line of application of the body causing the obstruction and gangrene.

In referring to the parts of the intestine they have been spoken of as upper and lower portions. The larger portion had evidently been dilated and hypertrophied because of its location above the point of obstruction, and the smaller portion contracted because below this point.

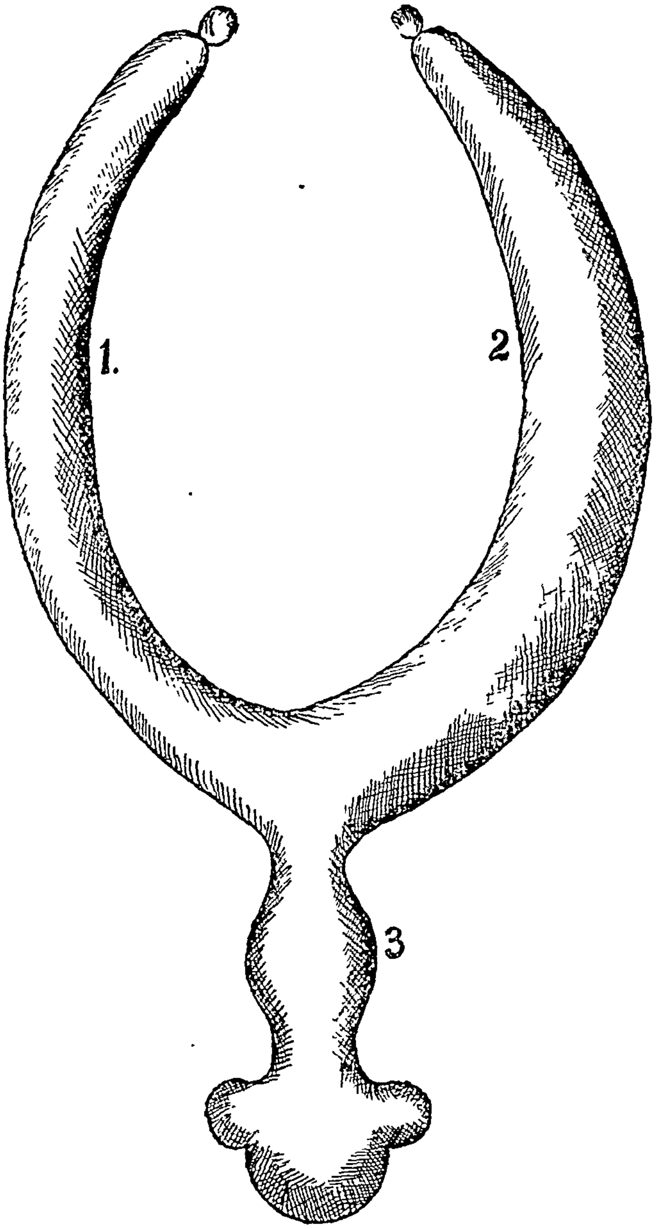

Fig. 3.—Illustration from Littre's first case, 1699. A Meckel's diverticulum found hernial in the left inguinal ring and canal. 1, Partie de l'iléon du côté de l'anus. 2, Partie de l'iléon du côté de l'estomac. 3, Appendice de l'intestin iléon.

The congenital diverticulum, Meckel's diverticulum verum, is a dilatation of the small intestine, representing a hollow appendix, which consists of all the intestinal membranes, and is placed at from eighteen to twenty-four inches from the cecal valve; although we do not quite assent to Meckel's view, that it is a remnant of the umbilical canal, it evidently has its origin in the development of the intestine in the umbilical vesicle. It accordingly is found solitary and attached at the above mentioned spot; it varies in length from five to six inches; it sometimes is wider, sometimes narrower than the intestine itself; it is frequently contracted at intervals of a conical or cylindrical shape and terminating in a round, clubbed or lobulated expansion. It either projects at right angles from the convex surface of the intestine, hanging unattached in the abdomen, or it passes off at an acute angle from the concave surface of the intestine near the mesenteric insertion, being attached to the latter by a falciform process of the peritoneum. In this case it is often placed parallel to the intestine. Occasionally a ligamentous cord, the remains of the omphalo-meseraic vessels, is found at its free extremity, and as this may, by its adhesions to various points of the peritoneal cavity, give rise to internal hernia (strangulation of the intestine), it receives importance in a pathognomonic view.—ROKITANSKY.

The specimen shows then the following conditions: A Littre's hernia of long standing, as evidenced by the old, firm adhesions about its base and outer surface of the button, and a gangrene of the wall of the intestine from an obstruction by pressure of recent occurrence.

Through the courtesy of the superintendent of the National Library of Paris, I have received a copy of the illustration, by Littre, of the part of the bowel and the diverticulum involved in his first case of hernia (Fig. 3).

I introduce the illustration here, the better to bring out the difference between a chronic *congenital diverticular hernia* and a *chronic intestinal wall hernia*, both being regarded as Littre's hernia; Littre's first case having been one of chronic diverticular hernia and his second one of chronic partial enterocele.

In reviewing my second case, I think four years ago there was an acute partial enterocele. At various times local peritonitis developed, resulting in the profuse adhesions with fixation of the bowel segment forming the primary acute partial enterocele, thus the acute partial enterocele gradually developed into chronic partial enterocele.

RETROSPECTION.

That the chronic form of partial intestinal wall hernia occurs is admitted by all, but not so that of the acute form. That the acute form of partial intestinal wall hernia occurs is still denied by authorities of note of today, among them Koenig.

This seems in a great measure to be due to the negative results obtained by Roser,[3] who in 1859 published the results of his experiments upon the cadaver with regard to this special form of hernia. Because he was unable, *first*, to apply a ligature laterally to the circumference of the bowel; and *second*, when he drew a segment of the bowel through a hernial orifice, the segment would not remain fixed, his conclusions led him to deny the occurrence of a free marginal segmental hernia. From 1859 to 1883, Roser's denial seems to have quite thoroughly saturated surgical atmospheres.

In 1883 two cases presented themselves for operation in Professor Albert's clinic. Both proved to be cases of incarcerated acute partial enterocele *without adhesions*. The first was a partial intestinal wall hernia of the small intestine incarcerated in the left femoral ring. The second was a partial hernia of the large intestine incarcerated at the right femoral ring.

Case 4.[2]—Woman aged 50, quite marasmic. On the right side there has existed a femoral hernia for some years, successfully retained by truss. On the left side patient until three days ago never noticed a swelling. On the first day, without any known cause, she was taken with strong pains in the abdomen; retching, shortly after vomiting. Physician recognized a left femoral hernia. Upon the third day of incarceration patient was sent to the clinic for radical operation. Here was recognized a walnut sized, firm, immovable irreducible swelling under Poupart's ligament of the left side. Continued vomiting until slight collapse and rapid pulse; no bowel movement for three days. Immediate operation. Cutting down, scraping through the hernial sac, there was found a dark blue, very congested intestinal pouch *closely lining* the inner surface of the sac, though nowhere adherent with it. The pouch presented the appearance of a large cherry of a bullet form. No adhesions. Drawing out the bowel, it proved to be small intestine. The compression ring occupied the convex side of the loop and surrounded as a circle a dark blue projecting intestinal pouch. *The pouch did not undergo any organic changes*, as *in rolling* out the intestines the pouch disappeared quite completely, so that the convex margin of the loop showed two slight compression rings, marking only a flattened protuberance. No changes in the mesenteric margin whatever; bowel replaced; wound packed; union by second intention granulation. Flatus passed the same day; second day after operation profuse bowel movement. No more vomiting was noticed. Left the hospital on the eighteenth day.

Case 5.—Well developed male, potator, aged 41. Messenger carrier. Patient says he never had a hernia or even a swelling in inguinal region. Wounded in chest at Koeniggratz in 1866; discharged cured. Always enjoyed the best of health since. Regular and easy stools without assistance; never complained of indigestion.

February 19, 1882. With an assistant he lifted two 2 centner iron cases into a railroad car. During this exertion he felt in the right lower abdominal region a sharp pain, followed by strong colicky pains. On this account two hours later he took to bed, and noticed for the first time an egg sized tumor in the right groin, which he painted with tincture of iodin. The abdominal pains continued and caused a sleepless night.

February 20. In the morning he vomited once. Physician advised patient to go to the hospital, but advice not heeded. Pains continued, anorexia complete. This condition continued several days, during which his general condition was improved, though the local tumor increased considerably; non-bowel movement for two days, then patient relieved with a senna decoction. Meanwhile patient consulted a second physician, who advised immediate removal to the hospital. The vomiting had not been repeated, though there had been a transitory tendency thereto.

February 22. Entered clinic. Swelling size of a man's fist in the right groin, covered with integument so stretched that it can not be folded, and of a dark red color. Its relation to the inguinal or femoral canal can not be given with certainty because of the dense peripheral infiltration. Consistency elastic. Deep indistinct fluctuation; percussion note hollow toward the hypogastrium; upon stronger percussion, tympanites with similar sound from the abdomen. Abdomen soft, not painful upon pressure; pains ceased. The general condition of patient seems not to have been seriously disturbed. Pulse 76, full and strong; tongue moist; face unchanged, with expression of a serious affection; slight rise in temperature. During the first day of the clinical observation the bowels moved profusely three times. The colicky pains had ceased, vomiting had not occurred again; patient complained only of want of appetite.

Notwithstanding the local picture, which was typical of a gangrenous hernia, the possibility could not be overlooked that the statements of the patient, especially as to the rapid occurrence and growth of the questionable tumor, might be based upon an error, and that possibly but an adenitis suppurativa presented.

February 23. Four days after its commencement, operation undertaken by Professor Albert. While waiting in anteroom tient had another bowel movement of watery consistency; ked to the operating table. *Operation.* Cutting down efully until the non-adhering bowel could be drawn out, which was found to be large intestine (cecum). Examination revealed that from the anterior margin (convex) in the vicinity of the ceco-ileac articulation a segment of the intestinal wall was incarcerated in the right femoral ring. The segment projected somewhat; the deeper organic changes, as suggillation, and in spots commencing gangrene (though no perforation), ceased at the base of the pouch. Death during the night of the fourth day in the hospital.

Just here I might add a case of Littre's hernia reported by Dr. J. C. Oliver.[4] Judging from his history of the case it would appear to have been one of acute incarceration of a segment of the bowel wall. His report of the case is as follows:

Case 6.—German woman, aged 33. Close inside the left spine of the pubes a small lump about the size and shape of a shellbark hickory nut, free from pain and tenderness. The impression given to the fingers was that of an enlarged inguinal gland. Operation revealed a small sac about the size of a hickory nut, which was laid open. It was found that a small knuckle of the intestine was caught in the external abdominal ring. The stricture was tight, and was notched with the herniotomy knife. The entire lumen of the bowel had not passed through the ring, only a portion of the circumference being engaged where the sac was opened. After fifteen minutes application of warm towels to re establish circulation, the knuckle of the intestine was returned into the abdominal cavity, wound sewed up and dressed. Bowels moved once during the night. Perfect union by first intention followed.

Dr. O. said when the case was first seen, I was inclined to think we were dealing with an enlarged gland, the diagnosis of the hernia being made at the operation. It was then found to be of the direct inguinal variety and that but part of the circumference was caught in the ring. A majority of the cases of Littre's hernia have been of the femoral variety, this being a direct inguinal hernia adds decidedly to its interest. (*Cincinnati Lancet-Clinic*, Vol. 35, p. 63, July, 1895.)

The two former cases seem to have prompted Adolf Lorenz, an assistant to Professor Albert, to a further and critical study of this unsettled question. His "Ueber die Darmwandbrüche," 1883, is the fruit of his investigations and observations in this direction.

In his introductory, he writes that "on some sides this latter form of hernia, *enterocele lateralis seu partialis acuta*, is today still opposed by an unwarrantable doubt, but which is rooted especially in theoretic speculation."

Thus, B. Schmidt[5] had expressed himself but a few years before: "It is claimed that at times only a segment of the free circumference of the bowel, opposite the mesenteric attachment, protrudes into a hernia. Until the bowel wall is found not adhering in the hernial sac or in its orifice, I must join with those who deny this form of hernia. (Roser, and others). A free intestinal wall hernia I have never seen, and know of none in the literature."

Lorenz's reply to these theoretic objections was the following record of a judicial postmortem made by an officer of the Vienna Health Department. "A four months, male infant, well developed, 67 cm. in length . . . The free margin of an intestinal loop situated about a meter from the ileo-cecal valve, protrudes quite loosely into a small sized umbilical sac lined by thickened, in places, gray pigmented peritoneum. In the intestine much gas and bile, colored soft contents. . . . It is not difficult to understand how, though the capacity of the sac be too small, to lodge an entire loop, yet it may not be too small to temporarily lodge a part of the intestinal wall." Notwithstanding the clinical and postmortem evidence furnished by these cases, facts meeting even the extreme theoretic objections insisted upon by Roser and Schmidt, today there yet exists doubt that acute partial intestinal wall hernia occurs, which is all the more unfortunate in that it has a tendency, as reference to the reports of these cases will show, to throw the inexperienced off his guard when encountering this dangerous and usually well masked form of hernia.

Albert,[6] in his "Chirurgie," which appeared a year later (1884) than Lorenz's monograph, writes that "even though seldom a small segment only of the bowel may present." Nevertheless, Koenig,[7] also a standard of today, in his latest edition of 1894, seems still to adhere to the opinion he expressed in his earlier editions (1883), namely, 'We deny, and least of all upon the evidence of the sections offered till now, that one is justified in accepting the existence of an acute arising incarceration of a small not previously pouch-like formed segment of a bowel."

In view of the evidence as furnished by the clinical manifestations seen in the cases reported above, and not forgetting that the operations in cases 4 and 5 were performed by no less distinguished a surgeon than Professor Albert, with observations made under his personal supervision, with faithful histories of the cases and with faithful descriptions of the anatomic and pathologic conditions encountered, he who would not believe such evidence must surely be a doubting Thomas; to say the least, if there be any question, it seems to me it is one of veracity rather than of fact.

Argument of theory is never so powerful as presentation of fact, and I am willing here to venture to weigh the "brute force" of clinical experience against the ephemeral force of pleasant speculation, and entertain no doubt as to the direction of the inclination of the pendulum.

Again, through the courtesy of Dr. Robinson, I am enabled to present another clinical manifestation of the bowel, which will materially assist in comprehending this question. In explanation of a new theory for the causes of hernia, he presents the following:[8]

"Irregular action of the gut-wall is the one cause which I wish to add, and one which I have not noticed in the books nor heard discussed. I gained the knowledge from the abdominal drain-tube. In laparotomy I use an aluminum drain-tube perforated by quite small holes. The holes are only about half as large as those in Keith's glass drain-tube. The holes are so small that one can not push a piece of bowel into one. Now, in a series of 100 laparotomies, Dr. Waite and myself have had three cases where the gut-wall had penetrated these small holes in the side of the drain-tube. We were obliged to steadily pull the tube upward and then tie the bowel wall with a ligature."

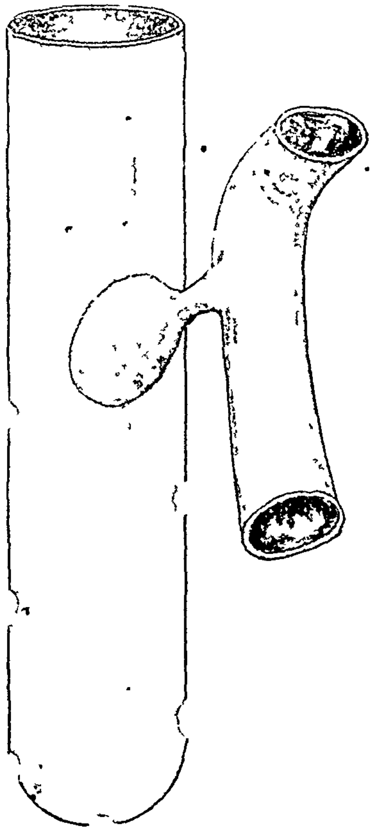

Fig. 4.—Showing irregular action of the bowel causing invagination of a segment of the bowel wall into opening in Keith's drain tube, strangulation followed, necessitating ligature and excision of diverticulum. (*Drawn by Dr Robinson from one of his cases operated upon for appendicitis.*)

[In this case Dr. Robinson, having such a bowel possibility in mind, had left word with the nurse to rotate the tube to prevent invagination. It seems during one of the intervals between the rotations, a segment of the bowel wall had invaginated itself so extensively that strangulation with suggillation changes had manifested itself; hence the ligation and excision. The primary operation was for removal of an appendix; the patient recovered after some fever and tenderness over the abdomen suggestive of local peritonitis.]

"In one case of Dr. Waite's, the drain-tube happened to be a glass tube of Dr. Keith's. and we were obliged to break the tube to safely liberate the gut-wall. Now, it appears to me that the hernia of the gut-wall in these tubal holes, is due to irregular action of the muscles in the gut wall. It is disordered peristalsis. The presence of the tube may irritate the muscles of the gut to act irregularly or in a disordered manner. It seems to me the same views can be applied in many cases of hernia. As the gut-wall approaches the small inguinal, femoral or the obturator canal it may become stimulated to irregular action just as it does around the hole in the drain-tube. In my opinion this explanation will account for the fact that the gut is found protruding through a very small aperture.

I have wondered almost as much how a loop of bowel could insinuate itself into such a small hole in the abdominal wall, as it could insinuate itself into a small round hole in my aluminum drain-tube. Keith's glass drain-tube has unnecessarily large holes, and in many cases it is common to find omentum, appendix epiploicus, or bowel wall engaged and even strangulated through one or more of these holes. In my aluminum drain-tube I have specially made the side perforations small in order to avoid the liability to hernia. Hernia through a small hole in the abdominal wall is probably produced from irregular action of the gut-wall, just as invagination is due to irregular muscular action of the bowel-wall.

" . . . The theory of irregular muscular action of the gut-wall as a cause of hernia I have never seen in literature or heard it discussed; but it seems to me to offer an explanation of some very small tight herniæ.

"There is some cause at work producing hernia on the right side more than the left. There is almost double the amount of hernia on the right so far as inguinal is concerned. Also the right side preponderates in regard to both femoral and obturator."

NOMENCLATURE.

Intestinal wall herniæ are usually included under the term Littre's herniæ. Still it must be borne in mind that a Littre hernia may be either a true diverticular hernia or a partial intestinal wall hernia. Both of his cases were of the chronic form.

His second case[9] was one of chronic partial enterocele, where a segment of the colon had become adherent and incarcerated at a ventral ring to the left and above the umbilicus.

Littre's first case[10] was his famous case of a chronic congenital diverticular hernia, where a Meckel's diverticulum, in this case given off from the ileum, formed the contents of the hernial sac, which was engaged in the left inguinal ring and canal.

The other two forms of diverticula, viz, the normal appendix vermiformis and the anomalous appendix described by Rokitansky[12] may also form the hernial contents, though the latter, seldom. These anomalous or false diverticula Rokitansky describes as follows:

"Such false diverticula consist only of mucous membrane and peritoneum, being herniæ of the intestinal mucous membrane resulting from the separation of the fibers of the muscular coat; they develop along the jejunum, the ileum and the large intestine, most often in large numbers (several hundred being met with in one case). They are pea to walnut sized, round, pouched; especially along the large intestine air from the nozzle of the instrument, which is directed against the spot which is to be treated. The degree of heat produced can be regulated by the length of time the bulb is held over the flame and also by the distance between the mouth of the nozzle and the surface toward which the heat is directed. The original instrument I have modified by making the nozzle straight instead of curved and by attaching a handle so that the air from a compressed air reservoir can be used. In applying the heated air to the ear, a hard-rubber speculum may be used through which the current of air is directed.

I have used heated dry air applied in this manner in quite a large number of cases representing various forms of ear disease, and can recommend this instrument in suitable cases.

In otalgia of all forms, by its aid I have usually succeeded very promptly in relieving the suffering of the patient.

In the so-called dry treatment of otorrhea, I have found it a valuable adjunct. My method of applying the dry treatment is to thoroughly remove the secretion with sterilized cotton, then dry the moist surfaces with heated air and follow this by insufflating a powdered medicament. The heated air used in this manner was found to be very grateful to the patient; it not only dries the middle ear but I have frequently noticed that it seemed to drive out some retained gas.

In the sharp recurring pains that frequently follow the rupture of the drumhead during an acute otitis media, the application of the hot air has given almost instant relief. I have not used the method in many cases of acute otitis media, but when I have done so the patients were considerably relieved from pain.

The effect of a hot air current upon the course of an acute otitis media is a matter to be determined by further experience. In chronic purulent otitis media I have noticed a decided stimulation of the mucous membrane and an increase of reparative action.

In treating catarrhal conditions of the Eustachian tube and middle ear, the heated air may be directed through a hard-rubber Eustachian catheter. I have also used the treatment in a number of throat and nasal diseases, and I am able by means of a long curved hard-rubber nozzle, to force heated air into the trachea and perhaps even lower into the air passages. It is my intention, however, to make this the subject of a later communication.

1929 Chestnut Street.

DISCUSSION.

Dr. Max Thorner—I have seen the device of Dr. Vansant and think it good, though I have not used it. Dry heat externally is always very grateful in middle ear troubles, and I do not see why dry heat internally should not be still better.

Dr. Randall—*The novel element in this is the dryness of* the air. I have known that heated vapors were better than cold vapors. The apparatus of Hubbard is really a repetition of Hartman's instrument of some five years ago, which has met with very little success. I shall try this method with great interest.

Dr. Marshall—I think hot air would be a distinct help if it could be made sterile.

Dr. Vansant—In my very brief paper I purposely refrained from citing cases. I hope that members will give the method a trial, and by experience find out its value. In using the instrument, especially with the compressed air reservoir, if you get too close the heat is *too intense. It should be given* in little puffs instead of a steady application. The instrument requires delicate manipulation. I think it may also be found of value in tinnitus due to Eustachian trouble. The instrument is used by dentists, and it is claimed that it lessens the pain in filling the teeth.

A FEW OBSERVATIONS OF SOME EASTERN EUROPEAN TOWNS AND HOSPITALS.

BY CASEY A. WOOD, M.D.

CHICAGO.

The disputed question as to the whereabouts of the largest hospital in the world will be decided in a year or so when the great *Ospedale Romana* is completed. This enormous establishment was begun in 1893 and has already cost many millions of *lire*. It will inclose within its limits, in northeastern Rome, all the various public hospitals, dispensaries, laboratories and clinics now scattered over the Imperial city. Instead of numerous isolated institutions, most of them housed in old, insanitary and dingy quarters, there will be but one collection of clean, well built, well drained, well ventilated, well lighted pavilions, replete with all the appliances, and provided with all the improvements that distinguish the modern hospital. On the other hand. the present father of hospitals, the great Allgemeines Krankenhaus at Vienna, grows more and more out-at-the-elbows, down-at-the-heels and baggy-at-the-knees. Nobody has better reason than the writer to appreciate how much the whole profession owes those ancient buildings in the Josephstadt, but surely the time has come for a change, not only in the nursing methods that have so long prevailed there, but in the old microbeladen walls themselves—a thought suggested by contemplation of the recent hospital erections that almost every small town in Europe and America seems to be making in response to the demand for absolute cleanliness on the part of everything and everybody who enters hospital doors.

When the city hospital in Rome is ready for occupation it will afford ample facilities for study and if a liberal policy be pursued toward foreigners, the Italian capital will make a most attractive and profitable center for medical study and may divert to itself some of that large stream of students that for so many years has been steadily flowing toward Vienna. The work done by Italians in all departments of medicine and surgery deserves to be better known than it is. Moreover, the language, spoken, written and, printed, is much more easily learned by Americans than is German, especially when the student has been assisted by a previous acquaintance with more or less French or Latin. In the province of ophthalmology and otology, with which the writer is most conversant, it may be said with truth that not to know enough Italian for translation purposes is to miss almost as much as not to be able to read French. Certain it is that the medical schools of Pavia, Turin, Rome, Naples and Palermo all have well informed ophthalmologists and otologists attached to them whose activities are of a kind by no means inferior to the best effort of the professors in German, American and French universities.

Although we found Athens in a state of general war depression, the hospital service seemed good in all its appointments. There is an ophthalmic hospital of considerable size for a city of 200,000, that is to say, its dispensary department is largely attended and it has twenty-four beds for indoor patients. Professor Anagnostakis, who had for years held the foremost place in Greek ophthalmology, having just died, I was indebted to the courtesy of Dr. Georgios Gazepy for my news. Although the limestone dust of Athens covers everything, including the bodies of its visitors, it does not appear to set up any particular affection of eyes, throat or lungs. The rather severe winter and the elevated site of the town probably serve to neutralize the harm done by the breathing of a summer air impregnated with lime and dust. So far as I could learn, Athens presents no peculiar eye or ear disease. There are very few cases even of trachoma, although intercourse with Asia Minor and Egypt is frequent and easy. Gazepy illustrated some of the difficulties the oculist who practices in the east has to contend with, by showing me his test cards and types, arranged for ten languages, all of which he is at times called upon to use, viz., Greek, Turkish, Arabian, Servian, Roumanian, Bulgarian, Armenian, French, Italian and Russian.

So far as we could learn, the unfortunate Greek army operating on the Thessalian frontier during the Turko-Greek war, was entirely without surgical equipment. A spasmodic attempt to establish a first-aid line was, after a time, made with the assistance of some English nurses that accompanied the troops as far as Volo, but even this was entirely inadequate, especially as the temporary hospitals had to be abandoned to the enemy shortly after their establishment. The polite Turk sent a message to these brave women, who had been instrumental in carrying out the project, that they entirely approved of the arrangements and found their quarters of great service! About the only consolation the Greeks seem to have derived from the recent contest is the fact, corroborated by our subsequent experience of the military hospitals in Constantinople, that their guns of the old Chassepot type had done more execution, both in killing and wounding, than the modern rifles of the Ottoman troops.

A most curious custom prevalent among Greeks of all ages and both sexes (but especially among the men), has a remote medical interest. One of its virtues is that it enables even prisoners condemned to solitary confinement, as most prisoners are in Greece, owing to public sentiment that opposes their competing with non-convict labor, to relieve the tedium of prison hours. Instead of twirling his thumbs, or chewing the ends of his moustache, as the nervous American is wont to do, to while away an idle moment the Greek deliberately provides for such a contingency by carrying about a string of beads that, by the way, have nothing to do with any religious observance whatever. These he draws from his pocket, wherever he may happen to be, and monotonously counts them one by one, or simply pushes them along singly, or two at a time, from one end of the string to the other. Surely this is an improvement on gum chewing, rocking chair exercise, or toying with some article of use or adornment as an occupation for nervous individuals, and is particularly recommended as an addition to the pharmacopeia of the neurologist.

As soon as we reached Smyrna evidences of smallpox, from which vaccinated Athens is fairly free, began to appear in the pitted faces of all the numerous races that throng the busy streets of that quaint old town. There seems to be no rooted objection to vaccination on the part of either Mahommedans or infidels; only, nobody seems to interest himself in the matter and there is no such thing as a compulsory law. Remembering Mary Wortley Montague's experience of inoculation one would expect prophylactic measures to be widely practiced among a people that are proverbially frugal, abstemious and personally clean. I looked in vain for signs of that ophthalmia which one sees everywhere in Egypt; the people seem to be almost as free of eye affections as the Greeks.

Constantinople is fairly well supplied with both indoor and outdoor hospital service, while the enormous military hospital at Scutari, first established by Florence Nightingale, is, according to Dr. Nicholas Senn, who inspected it during our visit as the guest of the Turkish government, an admirably conducted institution. I was entertained by Dr. Edwin Van Millingen, oculist and aurist to the Sultan, and son of that Dr. Van Millingen who was the friend and medical attendant of Lord Byron during his career in Greece. Van Millingen *père* was with Lord Byron when he died and made the postmortem on his body. The son has recently arrived from a visit to Smyrna and Cairo and in the latter place made a special study of trachoma. It is a generally accepted axiom among ophthalmologists that certain races, as well as the inhabitants of certain localities without regard to race, are practically immune to this formidable disease, and among these are counted mountaineers and negroes. Another affection said to be rarely or never seen in the negro is convergent strabismus, and this rule certainly holds good for the American continent. Dr. Van Millingen's experience in Egypt has disproved its universal application, as he found trachoma very prevalent among the pure native and immigrant negroes of Egypt. Although it is very infrequent he has seen, indeed had a case under observation in Constantinople at the time, well-marked instances of convergent squint among pure north African negroes. As a result of several months' examination of the various races in Egypt he found trachoma in the following proportions: Among the native (1,000 of each race examined) Mohammedans, 86 per cent., Copts, 85 per cent., Jews, 92 per cent.,-blacks 60 per cent. Among the foreign population, of which 200 of each were examined, the proportion was: English soldiers, 0; Syrians, Jews, Hindoos, Armenians, Turks, 24 per cent; negroes who have lived in the delta from four to thirty years, 50 per cent.; negroes born in Egypt, 70 per cent. Not only is the disease thus prevalent in such awful proportions, but it is more acute and more destructive than with us. Pannus is comparatively rare, but corneal ulcers are more common than in European countries. He denies that the Soudanese negro is more prone to contract granular ophthalmia than his cousin of the west coast, because he has a mixture of Semitic blood in his veins since the Soudan has only recently had intercourse with Arabia.

The principal military surgeon-oculist is Dr. V. Behjet, who is also the professor in the University. He has to deal, in common with other gunshot wounds inflicted during the war, with a number of interesting cases of injury to the orbit, some of them involving the ocular structures. His station was the Yildiz Hospital attached to that imposing array of barracks that surround and protect the palace of the Sultan.

I was much interested in the question of the prevalence of tobacco amblyopia, considering the large amount of the weed consumed in Turkey. Van Millingen informs me that he has never seen a case in a nargileh smoker during his twenty-six years of practice. All the cases of tobacco blindness occur in cigarette, cigar and ordinary pipe smokers. He thinks that the water-pipe undoubtedly prevents the disease, and that in the case of cigarette smoking the nicotin is largely absorbed by the lips. As might be expected also, alcohol poisoning (amblyopia included) and trichinosis are practically unknown among a population that really obey the commands of the Koran in the matter of wine and pork. In a country where blindness in both eyes is common from the formation of large scars over the whole cornea, Van Millingen tried the experiment of trephining a piece of opaque cornea when all other experiments had failed. He then placed over the globe a protective glass shell. The opening in the cornea often persisted for weeks and even months, and when the parts are kept aseptic the patient is able to see (in some instances to read), for quite a long period. When the wound finally cicatrizes the patient is not in any worse state than before the operation and has enjoyed some months of vision, during which time he may have transacted business or have accomplished something that with his blind eyes he could never have succeeded in doing. At any rate, the patient will be able to refer to the period of temporary vision as a pleasant experience when it was better to have seen the happy things of earth for a season than not to have seen at all.

The medical institutions of Moscow are admirably planned and equal in efficiency to those of the other large continental cities. Its public sanitation is, however, not as well looked after as in Berlin or Paris. The drinking water supply is defective and the sewerage system is very incomplete. Water for table use must be carted in casks from distant springs and the antiquated cesspool, with all its discomforts and dangers, still remains. The mortality rate is, notwithstanding these drawbacks, not high (29.5 per 1,000 of 1,000,000 population), although in 1896 there were nearly 6,000 cases of continued fevers of all kinds, 164 cases of smallpox, 2,380 of diphtheria, 3,500 of intermittent and recurrent fevers and 1,000 cases of chickenpox. The pure Russian is a sturdy and healthy-looking individual, somewhat given to drunkenness and other bad habits, but probably preserved from excessive alcohol and tobacco indulgence by having access to tea as a stimulant. The almost entire absence of smoking among the lower classes is strangely contrasted with the persistent use of cigarettes and cigars by the upper ten thousand. The latter smoke all the time, even between courses at meal time, while the peasant and his city equivalent never smoke, out of doors at least. The *samovar*, or hot water kettle for tea making, is everywhere, and it is astonishing to note the quantities of boiling hot tea drunk by all classes at all times of the day. We noticed a large number of persons going about in all the cities with their heads tied up in bandages, handkerchiefs, etc. It was as if there had been a recent epidemic of mumps. We found the trouble to be often middle ear suppuration, complicated with sore throat, decayed teeth, etc. It was explained that the Russians drink their tea so hot that actual burns of the pharynx and oral mucous membrane frequently occur. This sets up, by infection mainly, acute inflammatory processes in the walls and contents of the naso-oral cavities that often lead to serious consequences.

The majority of the hospitals, clinics, dispensaries and laboratories of medical and surgical Moscow are clustered together in a district called *Dievitchie Pole*, much as they are in Vienna, but with differences greatly in favor of the former city. The buildings are well separated, surrounded by plentiful breathing spaces and provided with an abundance of light and air. Here it is that most of the clinical and didactic teaching of the medical department of the Imperial Moscow University is given. The material for this purpose is practically endless and there seems no reason why the average Russian doctor should not receive an education quite equal to that furnished by the other continental schools. For example, in obstetrics there were, in 1896, nearly seven thousand accouchments in the eight public stations of the city, all of them accessible to students. The fact that out of the 31,000 births in Moscow that year, more than nine thousand were illegitimate throws some light on the advantages of this town as a center of obstetric study. A similar story could be told of general and special surgery in all their various branches. The bacteriologic institute, for instance, has a fine collection of animals and, during 1896, delivered to various public and private institutions more than twenty thousand bottles of serum anti-diphtheria, streptococcus infection, tetanus, recurrent fever, etc. I have been informed that the dental clinic, attached to the University Dental School (where five sessions of six months each are required for graduation) was attended by nearly ten thousand patients in 1896. Although the methods employed are still somewhat antiquated, it is housed in a building whose appointments far surpass anything of the kind we have in America. It has, among other conveniences, two laboratories, a library and a large museum filled with all sorts of anatomic, microscopic and chemic preparations.

There are many hospital and dispensaries not attached to the University, some of them of considerable size and importance. Ophthalmology is well represented among these. The Moscow Ophthalmic Hospital has 100 beds, with 722 indoor patients during 1896, and in it 1,750 major operations were done. Twelve thousand patients attended the outdoor department. Connected with this extensive charity is a blind asylum with beds for twenty-five inmates. An account of most of the other hospitals and medical conveniences of the city would be merely a tedious repetition of descriptions applicable to any other large European town, but there are at least two institutions peculiar to this part of Russia and of considerable interest.

The first is the great Foundling Hospital instituted by Catherine II. in 1764. Twenty large halls accommodate 980 beds for nursing infants. In summer most of these are transferred to the gardens of the Hospital in which are erected twelve *marquées* with 730 beds. This institution received: 1. Illegitimate infants deprived of their mothers. 2. Abandoned infants. 3. Illegitimate children whose mothers are living but who are unable to care for them at home. 4. Legitimate children to be cared for until they are a year old, when the illness of the mother or the poverty of the father prevents their receiving proper care. The average stay of the children in the hospital is thirty-seven days. For about a month each child has a special nurse and for ten days more one nurse looks after two children. When there is a dearth of nurses the mothers of some of the illegitimate children are requested to act in that capacity, when she is paid about $1 a month (fair wages in Russia) for the service. In case of a refusal the child is not admitted. The average daily attendance in

1896 was 1,005 children and 675 nurses. In an annex are buildings with 150 beds, usually full, where children and sick nurses are treated. All the children are vaccinated as soon as possible at a station where vaccine is also prepared and distributed gratuitously to all who apply. From the Foundling the children, regarded as wards of the State, are sent to certain districts in the country. Hundreds of villages receive their yearly quota, all of whom remain under the care of inspectors and physicians appointed by the State until they are able to take care of themselves. In spite of all sanitary and other precautions the death rate is enormous. Of about eleven thousand children cared for in 1896, 4,028 died, 5,175 being sent to the country. In the beginning of 1897 there were living in the districts above described nearly twenty-nine thousand small foundlings under the care of the hospital authorities. The income of the institution for 1895 was about $600,000.

There are several stations for the sale and preparation of koumyss (or kumys) in and about Moscow (the Maretzky establishment at Sokolniki, for instance), but if we are to believe most authorities the simon-pure article must be made near and drunk in combination with exercise on the *steppes* of the Volga. Samara, about a day's journey from Moscow, has two of the most noted and oldest of these Russian sanitaria, gotten up pretty much in the same style as similar resorts elsewhere. They are naturally surrounded by pine forests and artificially by lawns, gardens and pleasant walks. The management has also provided them with various kinds of outdoor amusements. One of the best is called the *Datcha Annaeva.* The season is May and June and the visitor is generally expected to take baths, outdoor exercise and to drink unlimited kumys. The Tartar mares feed on the rich plume grass and wild strawberry of the steppes, which give the milk of this region certain peculiarities. It is particularly rich in sugar, somewhat defective in fat and contains a portion of albumin resembling that of the human animal. It does not bear transportation and is readily affected by any departure from certain rules governing the collection and fermentation processes. The mares are carefully tended, never overworked and milked five or six times daily. Each milking yields about three-fourths of a liter of thin bluish-white milk, of a sweetish taste and peculiar odor. The milk is received in well-boiled wooden pails. The fermentation is brought about by adding, in a churn, fermented to fresh milk in the proportion of five pints of fresh to one of fermented milk. The whole is then churned for an hour and set aside in a temperature of 25 degrees R. The whole quantity begins to ferment in a couple of hours, when it is again churned and again set aside for several hours until it begins to exhale a distinctly alcoholic odor. Fresh milk is again added and the fermentation is stopped at the proper point by cooling. It is now bottled in soda water or champagne bottles and kept at 10 degrees R. The strength, chemic composition and therapeutic action of kumys vary greatly according to the method of preparation; it may be strongly alcoholic and decidedly intoxicant or it may be as faintly spiritous as the mildest Weiss Bier. Probably the outdoor air, regular exercise, pleasant surrounding and careful dieting of the kumys cures have as much to do with the improvement of patients as the drink itself, and this is the reason, no doubt, that the city stations are not as satisfactory places for treatment as the wild steppes themselves. Moreover, unless tested by an expert "taster," too little or too much fermentation of the kumys may occur and even the best mare's milk be spoiled in the preparation. "Cream Kumys," made of cow's milk, is entirely unlike the original, as it necessarily contains ingredients entirely unlike the mare's milk product and can not, therefore, be therapeutically compared with it. The kumys cure is regarded in Russia as a specific in all cases of chronic pulmonary diseases, anemia, chronic digestive derangements, most kidney diseases, scurvy and "general debility." The allowance for each patient is from six to sixteen bottles daily.

SOCIETY PROCEEDINGS.

International Medical Congress.

Twelfth Triennial Meeting Held at Moscow, Russia, Aug. 17-20, 1897.

The opening address in the Section of Neurology was presented by OBERSTEINER of Vienna, on the

PATHOGENESIS OF TABES.

He ascribes it principally to syphilis, although other causes may also be included: traumatism, intoxication, cold, etc., in addition to, or in the absence of, syphilis. We have reason to suppose that the pathogenic agent is a combination of different processes, co-ordinated, presenting various differences in intensity of action, yet all connected with some fundamental cause, probably toxic in nature, still unknown. It may affect all parts of the nervous system anatomically, but the spinal cord forms the essential seat of the lesions; a degeneration of the posterior bundles, especially those which are the intramedullary prolongations of the posterior roots. The alterations disclosed in the centripetal neurons are very important. They are constant and very pronounced in the central intramedullary part of these neurons, a little less in the posterior roots, still less in the cells of the spinal ganglia, and least in the peripheric nerve-fibers. These facts militate in favor of the hypothesis which locates the elective point for the action of the pathogenic agent in the most vulnerable part of the posterior root, the spot where it enters the medulla. Several symptoms of tabes, particularly the lightning pains, may be invoked in support of this theory. Darkchevitch announced that the lesions just described are not primary but secondary to inflammatory alterations in the peripheric nervous system and spinal pia mater, according to the results of his recent research. The lesions of the peripheric nervous system may cause an ascending degeneration in the sensory nerve-fibers, which does not stop in the intervertebral nerve ganglia but extends to the fibers of the posterior roots. In the medulla these morbid alterations are localized in the zone of the posterior radicular fibers which corresponds exactly to the localization of the medullary lesions of tabes in their initial stage. The anatomic modifications in the cells of the intervertebral nerve ganglia, consecutive to this ascending degeneration of the sensory fibers, are merely simple atrophy, and correspond in every particular with the alterations in the cells of the anterior cornua, caused by retrograde degeneration of the motor fibers. The leptomeningitis which induces the medullary lesions of tabes is localized exclusively or chiefly in the region irrigated by the posterior spinal artery. It only engenders tabetic lesions as the morbid process invades the posterior roots. One of the anatomo-pathologic characteristics of this leptomeningitis is the existence of venous alterations very much like the vascular affections of syphilitic origin.

GRASSET asserted that tabes can be clinically cured, although the lesions still persist; it can also be notably improved or at least arrested in its course. Antisyphilitic treatment is imposed whenever syphilis is certain, probable or even possible. It should be continued three months, but if no improvement can then be observed it is useless to persist further. The mercury can be given by the mouth; 5 to 10 centigrams of mercurous iodid, or 5 to 10 milligrams of sublimate, but Neapolitan frictions with massage under the arm-pits and knees, or along the spine, are [illegible] ra [illegible] tramuscular injections can also be made of [illegible] rcuric cyanid or gray oil. The frictic [illegible] ow [illegible] ten days of rest, for [illegible] m iodid should be administered in daily doses, increasing from 1 to 6 or 8 grams daily by the mouth or in rectal injections. If the effect of the antisyphilitic treatment is very marked, or if moderate, with a history of insufficient previous treatment, it should be continued by the alternate method, first mercury and then potassium iodid. If the effect is moderate with sufficient previous treatment, it should be suspended and resumed three months later. In the general formula for the treatment of syphilis, the specific medication should figure twice a year, in the spring and fall, each time three months. The antiarthritic treatment includes alkalines, iodids, arsenic, etc. They can be combined by giving 50 centigrams of alkaline iodid in solution at the two principal meals of the day, also a powder containing 50 centigrams of salol and 50 centigrams of sodium bicarbonate. The ten days following, give instead 50 centigrams of lithia salicylate in a wine-glass of alkaline water. The last ten days of the month the patient can rest or take twice a day 5 drops of Fowler's solution, or 50 centigrams of sublimed sulphur. The sclerosis can be combated with iodin preparations in antiarthritic, not antisyphilitic doses; silver salts if there is intolerance for the iodids, and lastly with ergot, although the latter may exert a depressing influence on the spinal cord or favor the development of gangrene. Large doses and too long continued use must be avoided. Medullary fluxion is the indication for it in tabes, consequently it is the medicament for acute or subacute attacks; much less useful in chronic cases and injurious in recurrences. If it is alternated with the iodid, it can be given three days each week or five days in two weeks, prescribing 5 centigrams morning and night the first day, and increasing by 5 centigrams each day up to 15 or 25 centigrams *pro die*. The diet is important, and if the sclerosis has invaded the kidneys very much an absolute milk diet should be imposed for a certain length of time. He treated of suspension and electricity as local treatment for the spine, and the necessity of seeking some remedy for the pains, with morphin as the last resort, never giving the syringe to the patient. He mentioned that the gastric crises can be treated with cerium oxalate, 5 to 15 centigrams three or four times a day, although his preference is a mixture of equal parts of chloroform and tinct. iodi. 3 to 4 drops two or three times a day. Injections of artificial serum can now replace the Séquard medication and nervous transfusion for the amyosthenia and asthenia. For this tonic medication, massage, hydrotherapeutics and electricity are applicable. The ataxia can be combated with the Frenkel method of re-educating the muscles, which Erb confirmed, stating that this constitutes the one advance in the treatment of tabes of late. The neurotic phenomena are more important in the symptomatology of tabes than has heretofore been realized. The first and the principal means to conquer them is suggestion. Local troubles, trophic, circulatory, etc., require special therapeutics. Raïchline stated that tabetics need substantial food, fresh air and rest, the same as tuberculous patients. Eulenburg rejects antisyphilitic treatment unless there are other indications that it should be prescribed. Dr. Daniel R. Brower of Chicago urged the importance of climatic treatment of tabes. A warm, dry climate without sudden vicissitudes, should be sought by the tabetic. If it is not a case of extremely gradual development, a sea voyage allowing abundance of pure air without exertion often results most favorably. Rest he added is another important factor in the cure. When the disease develops rapidly, immobilization in bed for six to eight weeks with daily massage and faradization of the muscles proves extremely effective. In cases that have developed rapidly, or cases with recent syphilitic antecedents, energetic specific treatment gives good results, but in his experience it has been rather deleterious in cases that develop slowly, or in which the infection is of long standing.

We translate in full Marinesco's address on the

PATHOLOGY OF THE NERVE CELL.

After remarking the great progress accomplished during the last ten years in our knowledge of this subject, thanks to Golgi, Flemming and Nissl, he spoke of the discovery of the chromatophilous element in the protoplasma of the cell, so called from its affinity for aniline stains, and continued: "These elements vary in shape and size with the different cells, but this is due, as I was the first to proclaim, to the structure and arrangement of the achromatic elements. This achromatic substance is composed of an organized part and a fundamental substance, as has been demonstrated by Flemming, Becker, Levi, Lugaro and myself. The organized achromatic substance is found in a large number of cells in the form of fibrillæ, and in the interior of the cells, in the form of a very delicate network. The fibrillæ of the prolongations are lost in, or rather continue into the cytoplasmatic network. In the spinal ganglia of the dog, after certain pathologic processes, the fibrillæ of the axis cylinder are plainly to be distinguished crossing the neck of the cell-like radiating bundles, whose fibrillæ give out collateral ramifications and disappear, the network of the cytoplasma. The crossbars of the network are inserted in the periphery of the cell or in the wall of the nucleus. The chromatophilous elements are molded by the shape of the interstices in the network, and hence the shape of these depends upon the shape of the interstices. The fibrillary part of the nerve cell serves for conducting, while the chromatophilous part owing to the chemic phenomena that occur in it, has probably the function among others, of increasing the potential energy of the current. We owe to Nissl the great discovery which was the starting port for the histo pathology of the nerve cell. He demonstrated that section of a sensory or motor nerve entailed a disintegration of the chromatophilous elements, a process to which I applied the term chromatolysis. It had been assumed since Waller, that the central end of a nerve and its center of origin remained intact. These secondary lesions consecutive to section of a nerve present a special type and differ from those determined by the action of the various toxic substances on the nerve cell. I have studied the different phases through which the nerve cell passes after section of the nerve: first, the reaction and then regeneration, or if this fails to appear, degeneration and atrophy. I have only been able to observe the reparation phase experimentally in animals in which the regeneration of the resected nerve occurred normally. I observed that it is characterized by a progressive hypertrophy of the nerve cell. The lesions of the nerve cell produced by the direct action of poisons are extremely variable, forming a marked contrast with the uniform type of the secondary lesions. The intensity of the poison and the variety of cell explain in great measure the variable reaction of these elements to toxic substances (Nissl, Marinesco). This field of primary lesions is so extensive that I will restrict my observations to the lesions produced by experimental anemia, by rabies, botulism, alcohol and tetanus, which have been the special objects of my researches. In experimental anemia, realized by ligature of the abdominal aorta, a peripheric chromatolysis in certain cells of the anterior cornu is observed; in others the coagulation of the cellular protoplasma brings out a shining network, that stains highly with methyl blue. Some cells, especially when the anemia is of long duration, show a destruction of the achromatic substance with fragmentation of the cell and its contents. Gaps and cavities can be seen in the interior of the cytoplasma. Rabies produces very distinct and characteristic lesions; but their intensity and form depend upon the intensity of the virus as in any other intoxication. It is in rabies that I have observed most distinctly the peripheric chromatolysis, which sometimes is so extensive that nothing is left of the chromatophilous elements but a very dense and highly colored perinuclear layer. This disappearance of the chromatophilous elements renders the structure of the achromatic substance very prominent, plainly showing the network with its rather large meshes. Destruction of the cross-bars of this cytoplasmatic reticulum results in the formation of cavities in the interior of the cell. This destruction is followed by the destruction of the axis cylinder and its prolongations, owing to the continuity which exists between the cytoplasmatic network and the fibrillæ of the latter. It is for this reason that lesions of the achromatic substance are serious and most probably irreparable. Babes and Sabrazès have found lesions in the cord of individuals who have died from hydrophobia. Lesions of the nerve cells produced by the toxin of the bacillus botulinus resemble, in some respects, those produced by rabies. Their maximum is found in the spinal cord and in the gray bulbar nuclei. The first stage of the lesion consists in the rarefaction and the disappearance of the chromatophilous elements. The lesion starts in most cases in the periphery of the nerve-cell, showing a more or less complete belt free from chromatophilous corpuscles. In a more advanced stage the chromatic substance is reduced to granulations of varying size or into fine powder. This is diffuse chromatolysis. As the degenerative process continues its evolution we can see in certain cells a tumefaction of the prolongations with deep color, and even holes in the interior of the cell owing to destruction of the achromatic substance. I must add that the neuroglic cells, considerably multiplied, join with the leucocytes to play the part of neurophagi—agents destroying the altered nerve cell. It was an interesting question to decide the effect on the nerve cells of repeated doses of alcohol, administered by the stomach or the veins. For this purpose I injected a dog of 7.5 kg. weight, with 100 grams of 50 per cent. alcohol in two days. After each injection the animal fell into a state of somnolence, and when he awoke manifested the phenomena of drunkenness. I found in the cells of the anterior cornua very marked lesions consisting in the disintegration and atrophy of the peripheric chromatophilous elements. In some other cells the lesion was localized, mostly around the nucleus. Tetanus determines characteristic lesions in the guinea pig at a certain period of its evolution. They are localized in a region occupying the quarter, the half or even three quarters of the cell, and usually on the side of the axis cylinder. I failed to encounter this lesion in rabbits inoculated with Brieger's toxin, with spasms of local contractions. The bacillus of the bubonic plague also determines in the cord of the guinea pig lesions studied by Babes and Lugaro—their conclusions confirmed by myself. In the less altered cells there is diffuse or peripheric chromatolysis. At a more advanced stage cavities or gaps form in the interior of the cell, by the destruction of the achromatic substance, and the great change in the nucleus renders these lesions absolutely irreparable. The vessels contain the bacilli of the plague which, Babes asserts, can even penetrate into the nerve cells. We have not confined our investigations to experimental research. Pathologic anatomy of the nervous system in man has revealed in many instances important lesions. The severe infections affect almost always the central nervous system and determine more or less serious lesions. In two cases of Landry's paralysis, examined with Marie and Ettinger, we found considerable lesions not only in the vessels of the cord, but also in the nerve cells. Other authors, Ballet, Dutil and Bodin, have found lesions of the nerve cells in Landry's paralysis. Other infections like pneumonia, typhoid fever, "granulia," are accompanied by lesions of the central spinal system, even when the functional disturbances are not sufficient to attract the attention of the physician."

Gaucher concluded his address in the Section of Dermatology with the statement that dermatology and syphilography should by no means be confined to a specialty, as no branch of medicine requires a more extended knowledge of general pathology. There is no tissue and no organ exempt from the possible action of syphilis, for instance. Much of what used to be called scrofula: ocular, aural, nasal, pharyngeal and osseous lesions, meningitis—only to be distinguished from tuberculous meningitis by its curability—hepatic and pulmonary lesions, etc., are now recognized as more or less tardy manifestations of inherited syphilis, while this disease dominates the entire field of nervous pathology. One of the new facts established is that we must not conclude from the absence of the microbe that an affection may not be caused by it. This applies particularly to tuberculosis and to leprosy, as Zambaco Pasha has recently established, proving the existence of aborted leprosy. Such is Morvan's analgesic panaris and certain cases of syringomyelia. The microbes not only act directly, but through their products. Many cases of exfoliating dermatitis are in fact a toxidermia, usually an unrecognized hydrargyria. It is through the nervous system that all the toxidermias and pathogenic eruptions develop. In infections also the nervous system is the intermediary between the microbian toxin and the cutaneous affection. Eruptions of the vesicular or bullous type are directly under the dependence of the nervous system. He also observed that dermatoses from auto-intoxication include all the cutaneous affections formerly called diathesic, so that the old theories persist, rejuvenated under the new name.

The usual discussion of "Appendicitis" elicited nothing new, although Roux observed that the reason he had never attempted to copy the Americans was that in his country the physician did not often arrive in time to operate in the first hour, which would be the ideal if every one lived in a hospital. Grinda proclaimed the superiority of an incision following the external edge of the sacrolumbar mass, curving in below, and carried parallel to and just above the iliac crest to a point 3 cm. from the anterior superior iliac spine. It is advantageous in all cases of retrocecal abscesses and when the location is indetermined. It opens up the cecum and appendix by the most direct route, avoiding loops of the small intestine, and ensures perfect drainage. In the question of "Hernias," Duplay and Cazin stated that time had confirmed the value of their method of radical cure without buried sutures, as performed on thirty-three patients. Twenty three can be considered absolutely cured; the rest only date from a few months. The sac is not resected, but utilized to tie, splitting it and tying it again and again in superposed knots (*vide* Journal, Vol. xxvii, p. 1318). The solidity thus obtained is extremely satisfactory.

A "Study of the Properties of Formol and of Parachlorophenol" was presented by Le Dentu of Paris, who announced that the sterilizing power of formol being twice that of sublimate, a 1 to 200 solution was ten times as energetic as a 1 to 1000 sublimate, solution. Also that formol has a most extraordinary deodorizing power. Gangrenous tissues lose their fetidity at once in contact with a 1 to 200 solution. It is valuable for the immersion of instruments in this proportion, as it does not affect them. I know nothing that can equal it for washing infected wounds, and I have always found the 1 to 200 solution well tolerated.

Laache of Christiania reported three cases of anuria, the urinary secretion ceasing completely for six days, with symptoms of obstruction from some mechanical obstacle. Venesection was performed and all the accidents disappeared, the diuresis amounting in one case to eight liters in twenty-four hours. He usually withdraws 400 grams, but in two cases he allowed one liter to be taken. Pick advocated venesection in pneumonia and cerebral hemorrhage, but in uremia prefers a rectal injection of a 10 per cent. salt solution, which Pisek endorsed, as the effect of venesection is transitory. Ughetti announced that pure uremia is always characterized by a lowering of the temperature, and hyperthermia is always due to some concomitant cause, convulsions or acute inflammation, not to any substance contained in the urine.

THE RÔLE OF THE VESSELS AND PARENCHYMA IN INFLAMMATIONS, was the subject of Virchow's address in the Section of Pathologic Anatomy, a comprehensive review by the master of the evolution of the present conceptions of inflammation. He referred to his still disputed assertion that the fibrin in exudations is a product of the parenchymatous metabolism and does not proceed directly from the blood, as generally assumed. He also called attention to the distinction between inflammatory and non inflammatory fatty degeneration. In the latter the cells pass at once from their normal into the fatty condition, which is merely a disturbance in nutrition, while in the former the inflammation consists in the intermediate stage of "cloudy swelling," which precedes the fatty degeneration. He grouped the main points in conclusion as follows: 1. Inflammation as we are able to define it now is not a single process with constant characteristics. 2. At least four varieties of inflammation can be distinguished: the exudative, the infiltrative, the parenchymatous or altering (metamorphosis or degeneration) and the proliferating. 3. The necessity of grouping these different varieties under one head is more diagnostic than scientific. We merely wish to distinguish inflammatory exudations, infiltrations, degenerations and neoplasms from the non-inflammatory. This diagnostic interest is strengthened by the therapeutic, in so far as the different varieties of inflammation require a certain similarity of treatment. Although the antiphlogosis of the present has not been able to retain the simplicity of the older methods, yet treatment even in the future will proceed on analogous lines to a certain extent, although perhaps no longer from one simple or the identical standpoint. 5. The condition of the vessels and of the local circulation is a source of considerable difference in the various kinds of inflammation. While inflammatory hyperemia seems to be in exudative and infiltrative inflammations, a chief cause of the disturbances that appear, it plays a subordinate part in degenerating and proliferating inflammations. The different course of the inflammation in vascular, extremely vascular and non-vascular tissues must also be borne in mind. 6. The condition of the parenchyma is likewise subject to no less important variations. The exudative inflammations entail the least, proliferating and degenerating the greatest, changes in the parenchyma. The infiltrative resembles more the exudative, but there is no inflammation in which the parenchyma is not involved to some extent. In many cases this participation is principally passive, as in the increased friability of the lung tissue in exudative pneumonia and the destructive effect of some infiltrations. In other cases, as in the secretion of mucus, the parenchyma produces through the activity of its cells the larger part of the exudation. 7. The character possessed in common by inflammatory alterations in the vessels and in the parenchyma is that the foundation for the alteration is to be found every time in an irritation which starts certain activities into operation (action, reaction). The first consideration of the diagnostician should therefore be to determine whether the process is fundamentally an irritative one or not. 8. The irritation involves nerves as well as vessels, specific as well as non-specific parenchyma. It varies according to the constitution of the irritated parts and the nature of the irritating influence. These injurious influences are sometimes of a mechanical, but far more frequently of a chemic nature. The irritating effects of many bacteria proceed from their chemic products. 9. The not unjustified comparison of inflammation to fever, founded on the rise in temperature of the outer parts, does not apply to inflammation in general but only to the fluxion to the inflamed part. The modern opposition to the essentiality of fever stands in the same line with the opposition (not very widespread as yet), to the singleness of inflammation. There are feverish diseases and there are inflammatory diseases, but there is no separate existence of fever alone as there is no separate existence of pure inflammation. The address will be found in full in the *Therap. Woch.* of August 29.

Gley and Ewald delivered the addresses on myxedema, the former dwelling on the importance of Baumann's discovery of iodothyrin and his own researches, which with others have determined the fact that the thyroid gland is not single, but that there is a thyroid system, including four accessory glandules. The extirpations of the gland which have not been followed by accidents are simply due to the fact than one or more of these parathyroid glands were left. Surgeons in future should learn to locate these glandules so as to leave one or more of them intentionally.

British Medical Association.

Proceedings of the Section on Public or State Medicine at the Sixty-fifth Annual Meeting, held at Montreal, Canada, August 31 to September 4, 1897.

(Concluded from page 646.)

Thursday, September 2.

The session convened at 10 o'clock, with the President, Dr. Lachapelle, presiding.

The first paper presented was

OBSERVATIONS ON POLLUTION OF GROUND AIR,

by Dr. James MacLoud of Charlottetown, P.E.I. He described the drainage system of his city of 12,000 inhabitants, deprecated the idea that Charlottetown has no well defined system of sewers, and that the arm of the sea upon which the city is built is polluted by sewage, poisoning their water to the imminent danger of public health. The paper was briefly discussed by Drs. Bryce and Oldright of Toronto, the latter stating that soil pollution had occurred in his city, caused by a broken "main." He illustrated a case of this kind where a medical gentleman's health was so seriously impaired that he recovered damages from the city.

The next topic was considered by Dr. F. Montizambert (Superintendent of the Canadian Quarantine Service, Grosse Isle, Quebec),

ON THE UTILITY OF QUARANTINES AS NOW CONDUCTED.

The general consideration of infectious diseases in connection with the subject of this discussion divides itself naturally under two heads: The prevention of disease from without getting into the country, and the dealing with it once it has entered in. A system of arresting disease at the coast and frontier entrances, and a system of preparedness in the interior communities. Neither of these is sufficient without the other. Coast quarantines and inland health organizations form the double line of sanitary defense. The interior communities ughout the length and breadth of the land have an interest, nd a very close and vital interest, indeed, in the fittings and orking of the quarantine service at the various ports of entry. But confidence in a quarantine system, however perfected, must never be allowed to lull us into a false sense of security to the neglect of striving ever more and more toward the sanitary improvement of the cities, villages and districts in which we dwell.

From the long period of incubation of some of the infectious diseases, and the relative shortness of the voyage from many ports outside the country, occasional cases of infectious disease in the stage of incubation, and the micro-organisms of disease lurking in unsuspected clothing or merchandise, may pass from time to time, in an invisible and unrecognizable stage and condition, the most efficient quarantine that is practically possible. This can not be entirely avoided without such routine detention of vessels and passengers at the ports of arrival, such routine disinfection of all clothing and merchandise from abroad, and such consequent interference with travel and traffic as would be altogether unjustifiable and impracticable. Quarantines must not be expected to do the impossible; nor must they be leant upon as an excuse for lessened effort inland. But, admitting this, they certainly may be depended upon for dealing with actual cases of infectious disease, with infected vessels and effects, and with those suspected of being infected. In this way they strain out and protect the country from a very large percentage indeed of the exotic disease which threatens it from time to time. And thus they do a great and invaluable work.

In the first place, healthy persons arriving at our ports in infected vessels may be held under "observation" at our quarantines during the accepted period of the incubation of the disease in question from the ascertained date of last possible exposure. In Great Britain, from her comparative smallness in area, the number of her ports, the extent of her shipping, the almost continuous influx of passengers from the Continent, the shortness and compactness of her railway systems, the completeness of her inland sanitary organizations, and the perfection to which the sanitary condition of the homes of our people has been brought, this precautionary "observation" at the port of arrival is replaced by "surveillance" at the place of destination. In Great Britain the ports are so numerous that to equip and maintain quarantines at them all would probably cost more than the average annual expense in money of letting in disease and fighting it inland; in Canada there are practically but four sea-gates of passenger entry from abroad, St. John, Halifax and the St. Lawrence on the Atlantic side, and the Straits of Fuca on the Pacific side. In Great Britain the rapid crossing in a few hours of passengers from the Continent offers no parallel conditions for the spread of disease amongst such passengers to those obtaining in an infected vessel, possibly crowded with emigrants, during a passage of nearly three weeks from Asia, or one of more than a week from Europe, to Canada. In Great Britain the place of destination is presumably reached within the first day after landing; in Canada it may not be reached until after a week or more of continuous railroad traveling. In Great Britain it may be possible to isolate suspects in separate compartments of the divided railway carriages during the short journey from port to destination; in Canada during the possible many days travel in our large and undivided cars no such isolation would be practicable; but with the constant coming and going of passengers into and out of the cars at every station and cross-line, any infectious disease would be liable to be spread broadcast through the country. In Great Britain the inland sanitary organizations and the sanitary condition of the homes of the people are considerably nearer perfection than they are, as yet, in this country.

For such reasons as these Canada can not depend to the same extent as Great Britain upon inland "surveillance," and "observation" of suspects at quarantine must form part of our system of protection. Accordingly, in becoming a party to the Dresden Sanitary Convention, this country accepted its conclusions fully, and without the reservation made by Great Britain in her own case, that healthy persons landing from infected ships should not be detained.

In the second place, under the regulations in the United Kingdom no mail matter, except that by parcel post, is liable to detention or disinfection; in Canada disinfection of the mails is not forbidden, and is sometimes considered necessary. Notably is this the case, for instance, for the local mail arriving at Victoria from China. But little is known of the sanitary conditions in the interior of China, and that little is anything but reassuring. The disinfection of the mails from that country is, therefore, considered advisable.

In the third place the regulations of the Local Government Board for ports in the United Kingdom limit the term "infected" to infected with cholera, yellow fever or plague.

Under the Canadian regulations actual cases of any of the infectious diseases are removable at quarantine so as to prevent the importation of new cases, even of the minor diseases, to become fresh centers for the spread of infection throughout our country. And the arrival of all classes of infectious disease is notified inland from our coast quarantines. Under this head perhaps the most noteworthy difference between the two countries is with regard to smallpox. In the Canadian regulations smallpox is included amongst the graver forms of infectious disease, and there are indeed special regulations concerning it. According to the English regulations, and the English usage, as reported to me, a vessel arriving at a port of the United Kingdom with smallpox on board, is not considered an infected vessel at all. In Canada the protection of the people by vaccination is not sufficiently complete and general to justify us in excluding smallpox from our meaning of the term "infected" as applicable to vessels and persons arriving at our sea-ports.

With regard to our minor ports, and our land frontiers, we have regulations which can be fully amplified should an emergency so require. But with respect to the importation of disease from Europe, Asia, Central and South America, etc., via the United States and across the frontier, we put our main dependence upon their protection of themselves by the well-worked quarantine of our southern neighbor, such as those of Boston, New York, Portland and New Orleans, and their admirable national quarantine service.

Dr. J. A. Duncan, secretary of the Provincial Board of Health of British Columbia, in the discussion dwelt particularly upon the plan of preparing the ship and passengers in health at the starting point in China or elsewhere, and that quarantine stations of foreign countries should be thoroughly equipped. The recommendations he submitted would prevent delay at the strait of Juan de Fuca and other ports along the Pacific coast.

Dr. S. MONCKTON COPEMAN of London, England, referred to the threatened cholera invasion in 1893 in England, and the plan in vogue to resist the invasion of the disease in his country by the efficiency of the medical men in the Public Health service.

Dr. A. R. REYNOLDS, Commissioner of Health, Chicago, pointed out the utility of the quarantine system that was practiced in New York City during the summer of 1893. The result was, when we were receiving people and guests from the world over, not a single case of cholera developed in Chicago during the World's Fair.

Dr. HARVEY LITTLEJOHN of Edinburgh thought there was no practical difference in the quarantine system of the countries either in the United States, Great Britain or Canada. What ever difference or system adopted in the United States was accounted for by circumstances arising at the time such system is in effect.

Dr. FELIX FORMENTO of New Orleans, La., spoke of the State quarantine that is in vogue in the State of Louisiana. He advocated that in some States they are very well able to protect themselves. He also argued that there is much to be said *pro and con* in the matter of the United States Government taking charge of State sanitation. In New Orleans, yellow fever is constantly threatening us, and we must protect ourselves from foreign invasion of that disease. Since 1878, however, we have had no yellow fever in the city of New Orleans except one or two cases in 1879, and possibly one or two cases in 1882 and 1883. Maritime sanitation is the term that should be used when the Federal Government takes hold of this matter. We have gradually modified the system of detention by disinfection of a ship so that three days' observation is the minimum limit of detention of passengers. This will protect public health and commerce, and in this we have been successful. This is American sanitation.

Dr. WOLFRED NELSON of New York—Constant vigilance is necessary in the South for yellow fever. On the Isthmus of Panama the distribution of yellow fever occurs continually, and if it were not for the magnificent quarantine system in some of the Southern cities, the South would be swept by it.

SOME ALLEGED DANGERS OF VACCINATION AND THEIR PREVENTION,

was read by Dr. S. MONCKTON COPEMAN, Medical Inspector to the Local Government Board, London, England.

The writer maintained that the main practical danger arose from the uncleanly habits of a patient (vaccine). Microbes could be excluded by the use of glycerinized lymph, although the vaccinator should use precautions in having his instruments and hands clean. If the elementary principles of cleanliness are carried out by the operator and the quality of the lymph product pure, no danger from the operation will ensue. The diseases that have been known to occur, if these precautions are not observed, are erysipelas, abscess and septicemia. The transmission of syphilis and leprosy can not be gainsaid. Septic inoculation may be accomplished by the instrument or hand. If erysipelas should develop, it will arise within three days of the operation. Vaccinia occurs in a certain number of cases. Comparing the percentage of deaths due to chloroform, ether and anesthesia to those due to vaccination, the preponderance of deaths attributable to the former is greater than could be attributable to vaccination, and yet we would not be without anesthesia. In England fifty deaths occur every year attributable in one way or another to vaccination. Some writers deprecate the inoculation of calf lymph, but a person need not be required to submit to vaccination unless it is procured from the calf. The writer's method of procuring the lymph from the calf and preserving it consists in the well-known method of preparing it with 50 per cent. of chemically pure glycerin and sterilized water. This will insure the absolute extinction of all germs and render it free from pathogenic bacteria of erysipelas, tuberculosis, etc. Scientific observation and official recognition is in favor of calf lymph.

Dr. A. R. REYNOLDS, Chicago—The use of recent glycerinized lymph bids fair to do away with the fear of vaccination, as it remains pure for sixty days, and is growing in favor every year.

Dr. WYATT JOHNSTON of Montreal contributed "Some Notes on Room Disinfection by Formaldehyde," or, "Experiments in Household Disinfection." The paper was read by Dr. Littlejohn in the absence of the author. The desiderata obtained from its use are freedom of injury to the goods treated. Its penetration is more powerful than the fumes of sulphur. The apparatus and its use was shown by Dr. D. D. MacTaggart of Montreal. It consisted of an air-tight tent which is used to place the goods in, and the condensed formalin vapor escapes under a pressure of fifteen pounds.

THE RELATIONSHIP OF THE HEALTH OFFICER TO THE REGISTRATION AND CERTIFICATION OF DEATHS

was read by J. R. Kaye, M.D. He advocated reform. A portion of his paper was historic. In 1837, in London, the act was decreed that certification of death be required, and the Registration act and great act in London, 1875, enjoins upon medical men to certify, to the best of their ability the cause of death, and specifically so, and not to use ambiguous terms, and to do away with significant symptoms as a cause of death such as jaundice, dropsy, hemorrhage, etc.

Dr. P. H. BRYCE—In Ontario, the act of two years ago requires that the householder and attending physician certify and both be satisfied as to the cause of death. This makes the correctness more accurate and illegality less liable to occur.

Dr. THOMAS CARR of Essex, Eng., and the author closed the discussion by stating, that registration in England is completely carried out, and that all returns should be made to the Health Officer for transmission to the registrar general.

The subjoined list of papers were read by title: "The Sanitation of Militia Encampments" by Dr. W. Henry Egle of Harrisburg, Pa.; "Tuberculosis in Animals in Relation to Human Tuberculosis," by Dr. G. de Schweinitz, Director of the Biochemic Laboratory, Department of Agriculture, Washington, D. C.; "Consumption in Australia," by Lane Mullen, M.D., of Sydney, Australia; "Notes on Bermuda as a Winter Resort," by Eldon Harvey, M.R.C.S.; "A few Observations on Bermuda," by Surgeon-Captain H. A. Cummins.

FRIDAY, SEPTEMBER 3.

The Section was called to order at 10 A.M. with President LACHAPELLE in the chair.

The first paper,

ON THE DIFFERENT PROCESSES RECOMMENDED FOR THE TREATMENT OF SEWAGE,

was prepared by Mr. GEORGE JANIN, C.E. (formerly of the Corps des pontes et Chaussées of France), Montreal and was read by Dr. C. De Martigny.

The author described the various attempts which had been made in other countries to purify sewage, with the indifferent results attending the same. The soil is the instrument of purification, although air and water may move the sewage, and by so doing a phenomenon of slow combustion goes on and is the best method of purifying sewage. Mr. Janin is an enthusiastic exponent of purification through filtration or irrigation in this method of permeable soil. The effects of this in France and Germany were set forth as abundantly successful, both from the hygienic and economic points of view. Some of the chief features referred to were, that the town, city or municipality secures a certain amount of land into which the sewage is poured by means of ditches. The porous nature of the soil permits percolation, while simultaneously the chemic properties of the earth render the sewage matter innocuous in its passage, the result being that the effluent, when it reaches the stream or river into which it is to finally empty itself, is free from organic impurity and does not in the slightest degree contaminate the water with which it mingles. As for the economic results it was pointed out that in France and Germany great profits had accrued from land so treated, the crops being nearly double and the greatest eagerness being displayed to acquire purification on land, as it is called, in the neighborhood of large cities. If there had been any failures in the instances in which the system of filtration or irrigation had been employed it was not owing to the principle involved in the system itself, but to an improper application of those principles. The system is approved by all the great sanitarians of both France, Germany and England and he instanced the case of England particularly, because in that densely populated country, with its large cities and the comparative smallness of its rivers, it had been found necessary to pass a "Rivers Pollution Act," and several systems had been tried to comply with the terms of that act, soil purification being finally accepted by those in authority as the best and indeed the only system [illegible]

Dr. HARVEY LITTLEJOHN of Edinburgh, [illegible] with Mr. Janin that the system which he [illegible] the only one from which complete success could be expected. Sewage has been so treated in England and Scotland during the last ten years. Precipitation by lime was adopted many years ago, although no known precipitation is reliable. No doubt the urgency of this matter is not so great in Canada and in the [illegible] States [illegible] was [illegible] glance, but still, if he [illegible] oul [illegible] t [illegible] the time to begin to make provision for the purification of their sewage in large centers of population, while their beautiful rivers and lakes had not become as the rivers and lakes in older countries had been allowed to become, simply sewers, past cure or hope. The passing of the "Rivers Pollution Act" in England made it incumbent upon local authorities to exert themselves to devise a scheme for sewage purification. Indeed, the local government board had brought pressure to bear upon the municipal authorities with the result that several experiments had been tried, such as precipitation, but that which had given most satisfaction was the soil irrigation. The difficulty, however, in England was that land was enormously dear, so dear, indeed, as to preclude the possibility of its being purchased in many instances, certainly in the case of land situated close to large centers of population, by the municipal authorities. Land is still comparatively cheap in this country and he thought now was the opportunity to provide for the future.

Dr. Wm. Oldright mentioned that filtration by irrigation has been successfully introduced in London, Ont., and that crops raised there were very valuable because the irrigation was the best he had ever seen.

Dr. P. H. Bryce added his testimony to this fact also, viz., that the action of the asylum authorities at London, Ont., where the experiment of sewer purification by the soil had been to such an advantage that potatoes raised upon the land thus irrigated averaged a value of $300 per acre, wholesale price. To conduct a sewage farm with success, the sand should be sharp and the sewage poured on; the running of the water would not be interfered with by our winter climate.

Dr. De Martigny explained that in several of the towns in northern France and Germany the experiment had been successfully carried out in the winter, when the frost was three feet deep in the ground, while the crops resulting from the land thus used were wonderful in their increase.

Dr. C. O. Probst—In Ohio broad irrigation is not used. There is not a river in the State that has pure water, and we will have to face this question. Alum treatment will precipitate the sewage and by that means we can purify the water, but the expense attending this is great. He then instanced the cities in that State where this had been tried.

Dr. J. C. Shrader of Iowa City, said that in his State it is a very difficult thing to purify the streams, or prevent the contamination of the waters. So far as the Mississippi and Missouri Rivers are concerned, it has never been attempted.

Dr. H. J. Herrick of Cleveland, Ohio—This question is occupying the attention of the world. Cleveland with her 400,000 inhabitants, drinking the water from Lake Erie, suffers at times from the lake water becoming bad. I believe that the system suggested by the author of the paper is the best one. Nature takes care of the sewage by oxidization, sedimentation and aeration. Then the disinfection takes place in the soil below. We should secure a large surface to do this.

Dr. Woods Hutchinson of Buffalo thinks that admission of air to soil is a desideratum necessary, and that the micro-organisms should have credit for a portion of the work they perform, for were it not for the purifying action of these bacilli in the soil this experiment or irrigation would be a failure resulting in the poisoning of the soil and the contamination of the district with disease germs.

Dr. Alexander Johnston—The present process consisting of precipitation of sewage by lime and alum has been discarded; that is, lime has been discarded and final filtration is made through a sand base. The difficulty really consists in irregular discharges of sewage, and its treatment by chemic processes can not be correctly done.

The next paper was

RESULTS OF MECHANICAL FILTRATION PLANTS IN ONTARIO,

by Dr. J. J. Mackenzie (Bacteriologist Provincial Board of Health of Ontario). The author referred particularly to the methods in vogue at St. Thomas, Ontario, where the water was purified to the extent of 96 to 99 per cent.

Dr. C. O. Probst instanced the experiments by the dual mechanical filter that had been tried at Lorain, Ohio, situated on Lake Erie, where during the first week 2.58 grains of alum to the gallon of water was used and showed such bacterial deficiency that the water was 98.9 per cent. pure. During the second week 2.50 grains of alum were used and the water was 98.4 per cent. pure. In the third week, when 2.27 grains were used, the water was 97.5 per cent.; in the fourth week, when 1.7 grains were used, the water decreased to 90.9 per cent., and the fifth week with 0.94 grains the water decreased to 86.3 per cent. It would cost $5,000 per year for alum alone in that place to procure pure water.

The succeeding paper, by Dr. F. F. Westbrook, Bacteriologist, State Board of Health of Minnesota, was entitled

A PRELIMINARY COMMUNICATION ON THE BACILLUS OF EPIDEMICS OF DIPHTHERIA.

The author cited one case where seventeen examinations of the secretions of the throat in one child had been made, covering a period of 181 days, in which fifteen of the examinations showed the typical bacillus diphtheriæ. Antitoxin and corrosive sublimate solution, 1 to 1000, and even 1 to 250, failed to remove all the bacilli diphtheriæ in this case. The paper dealt largely in statistics regarding the typical and atypical variety of the bacilli and how children may be reinfected.

The next paper, by Dr. E. B. Shuttleworth, Bacteriologist to the City Board of Health of Toronto, was

OBSERVATIONS ON THE ETIOLOGY OF DIPHTHERIA.

In 1,000 cases tabulated by the author he showed that in Toronto the throat and tonsils are prone to the disease.

The following papers completed the program: "The Future of Public Health, Judged by a Quarter of a Century's Experience of its Past," by Dr. C. N. Hewitt of Red Wing, Minn.; "Paper on Yellow Fever," by Dr. Wolfred Nelson of New York.

PRACTICAL NOTES.

Orthoform, a New Local Anesthetic, does not substitute cocain, but has a field peculiar to itself. It is absolutely non-toxic; applied as a powder it produces a slow progressive anesthesia wherever there is solution of continuity, lasting hours and days. It has no effect upon sound skin or indurations, but in all burns, wounds, fissures, ulcerations, excoriations, etc., it abolishes sensibility, diminishes the secretions and exerts a pronounced antiseptic effect. Orthoform is a methyl ether compound of amidoxybenzoic acid, discovered by Drs. A. Einhorn and R. Heinz of Munich. In combination with hydrochloric acid it forms a soluble salt which can be administered internally, ½ to 1 gram several times a day, to remove the pain in cancer and round ulcer of the stomach. Intra-urethral injections in chronic gonorrhea have also proved effectual.—*Semaine Méd.*, September 1.

Cocain as a Safeguard in Anesthesia by Chloroform.—A London chloroformist claims that the trigeminus is responsible for the dangers to the heart and respiration by the reflex irritability of its terminations at the mucous membrane of the nose. His method is to anesthetize the nasal mucous membrane, which is done by requiring the patient to blow his nose and then, leaning forward or sitting, but never lying, to sniff a centigram of a powder consisting of 10 per cent. of cocain hydrochlorate and some inert substance. Repeat in about three minutes, and begin use of chloroform. In fifty cases in which cocain was employed in this manner the conclusions were: The commencement of anesthesia is less disagreeable to the patient, who never makes defensive movements; oftentimes the excitement stage is wanting, and is always slight, except in cases of alcoholics; during anesthesia the patient rarely vomits, and if vomiting does occur it is accompanied with slight retching; upon awakening the patient experiences no disagreeable sensation and is not troubled by the after-smell of chloroform or ether.

The Toxin of the Gonococcus has been isolated by Wassermann from the dead cocci. It is so virulent that the smallest amount produces inflammation at the spot where applied, fever and violent pain in the muscles and joints. This discovery explains the phenomena which occur in gonorrheal affections even after all the cocci have disappeared. The best medium for cultivating the gonococcus has been found to be the albumin of animal serum. He prevents coagulation when heated, the principal difficulty hitherto, by the use of nutrose (casein, sodium phosphate). 15 c.cm. pig serum are mixed with 30 to 50 c.cm. water, 2 c.cm. glycerin and 2 grams nutrose, added and sterilized over a spirit flame. This is enough for six or eight plates. He concludes by liquefying a few 2.5 per cent. agar tubes, and he has then a culture medium in which the gonococci thrive finely. He succeeded in isolating the toxin by adding peptone bouillon to the cultures and killing them after a three days growth.—*Deutsche Med. Woch.*, August 12.

THE

Journal of the American Medical Association

PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance	$5.00
Foreign Postage	1.75
Single Copies	10 Cents.

In requesting change of address, give *old* as well as new location. Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,

No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago. Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the *Editor*, and *all communications relative to the business of the* JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, OCTOBER 2, 1897.

INTERNATIONAL MEDICAL CONGRESSES.

Among the medical events of the present year, which has been in this respect a rather notable one, the International Medical Congress at Moscow ought not in the natural order of things to be considered the least. Its cosmopolitan character, drawing its attendance from all countries, and presumably from the most eminent in each, ought to give it a rank amongst medical conventions well above any merely national and annual gathering, and should lend to its deliberations an equally enhanced importance.

It is doubtful, however, whether there has been, at least of late years, an international congress that has met expectations, or that has not in fact been a disappointment to an extent much beyond the mere failure to reach some very high ideal. The causes for this are numerous and some of them have been recently summarized in an editorial in one of our French contemporaries, the *Medical Week.* It finds that this, like other congresses, failed in organization, and that the adoption of four official languages was a serious embarrassment, crippling discussion, as comparatively few of the attendants, even amongst the Russians themselves, who are as often as any others accomplished in this direction, were such polyglots as to be able to intelligently follow all the communications. This is and will be an embarrassment in any international meeting of the kind till some one or two languages become universal, and must have been especially felt at a meeting in a country like Russia, whose vernacular is almost as unknown to foreigners as the Hungarian or Japanese. The protests against the restriction of the polyglot privileges in the late Congress are fresh in everyone's recollection, and the adoption of the four official languages was practically a necessity, but it was none the less an embarrassment. Such a gathering will probably have to continue to be a sort of medical Babel and that is not one of the least of its disadvantages. In fact, it is perhaps the most serious one of all, as it prevents that interchange of opinion and scientific communion which it is the great object of these assemblages to favor. The attendance at any meeting of the kind will be predominantly from the country in which it is held, and when this is one whose language is unfamiliar to the great mass of cultured physicians, the members from the outside can the better appreciate the embarrassments of an international congress.

This leads naturally to the second objection raised by the *Medical Week*, viz., the immense attendance at these gatherings, which seems to increase with each triennial meeting. The opportunity of a pleasure trip at reduced rates and of meeting and hearing the celebrated men who are on the program insures a large attendance, especially from the country in which the congress meets, but this fact itself reacts badly upon the scientific value of the session. There is also, under present conditions, necessarily a lack of discrimination in the publication of papers read, and the result is overloaded volumes of contributions of very unequal value. There is still an additional objection connected with these large numbers in attendance, they make it impossible for them all to be included in the invitations to official entertainments, etc., and it would be a task for something more than human wisdom and tact to avoid occasions for some heart-burnings and disappointments.

The cost of these assemblages is also mentioned as a drawback, and it is stated by the *Medical Week* that municipal and national governments are beginning to be alarmed at the increasing expenses and to seriously consider the question of their expediency. It would certainly be unfortunate if what ought to be the highest medical convention of the world should thus come to be officially considered a nuisance, and if there is any imminent or remote danger of such a thing happening, for that is what it would practically amount to, it is advisable to use prompt measures for its avoidance. The remedy proposed by our contemporary, that of making these congresses less frequent, partially meets this objection, but leaves the others mentioned still in full force. The crowds, the lack of discrimination, the inevitable defects of organization and the confusion of tongues would still be as objectionable as ever whenever the congress took place, no matter what the interval may be, unless something is done to amend the present existing conditions. Perhaps if the congress could be made altogether a delegated body with limited membership, each national organization, general or special, sending a proportional number of delegates, it would relieve the present difficulties and also make it a more representative and international body, as well as elevate its scientific character. In addition to the regular delegations the official committee might be authorized to specially invite possibly an equal number of the most prominent members of the profession from all parts of the world, and in this way the congress might be made truly representative of the highest medical science, and fitted to discuss and decide important international medical questions. To be a member of it would then be one of the highest honors in the profession, its decisions would have weight not merely amongst medical men, but also with rulers and governmental bodies, and it would have an influence far beyond what it has at present or is likely to have under the present status and with the tendencies now apparent.

The wish expressed by the *Medical Week* that the next session of an international medical congress, at Paris in 1900, will be utilized to inaugurate a new era in these events with the opening of a new century, is one that ought to be most heartily endorsed by the medical press and the profession in general. During the next three years some valuable suggestions ought to be offered that can materially aid in the reform that is undoubtedly so necessary.

THE SO-CALLED FRUIT CURES.

The conditions of true therapeutics impose the obligation of knowing how to utilize all the resources of nature that may relate to our simple selves, whether they be pharmaceutic, surgical, moral or hygienic. There is consequently, with the advance of modern and rational methods in medicine, a growing disposition on the part of the latter-day physician to do away with the use of drugs as much as possible, and to rely more upon the influence of hygienic and dietetic means in the prevention and healing of disease. In fact, we are modified by the alimentary regime even as to sociologic influences, and men can no more escape the effects of alimentation than they can other great mesological conditions. To say that diet is a necessary adjunct in the treatment of disease would be to repeat the obvious; but many of us do not recognize that it is easier to improve health than to cure sickness, and that much of this improvement, if not the greater part, is brought about by well-regulated dietetics. In no other country than ours is there a greater variety and abundance of food, and in none is it worse prepared. Consequently dyspepsia and Bright's disease are almost as marked characteristics of American nationality as the consumption of beefsteak and of mixed iced drinks of alcoholic nature. It is far from our purpose to condemn the meat-eating proclivities that obtain among our people. Indeed, if they were not nourished as they are, the English-speaking race would not hold its present place in the affairs of the world. It is rather our wish to protest against the too exclusive use of meat and starch and to modify this diet by the introduction of the kindly fruits of the earth, which teeming orchards and full vines have at this season brought forth in such profusion as to induce the enlightened physician to look upon them as a preponderating influence to counteract the amylaceous dyspepsia that inflicts two-thirds of our patients.

The uses of fruit as a medicament appear to be very little known, not only in the United States, but among English-speaking people generally, and no special publications comparable to the German ones on the *Obst* cure are to be cited. A comprehensive article, "The Grape as a Food and Medicine," in the *Medical Record* of Oct. 10, 1885; the "Grape Cure," in "Reference Hand-book of the Medical Sciences," and "The Appendicitis Craze and the Grape Cure," *Maryland Medical Journal*, Oct. 24, 1896, all contributions by the same writer, seem to be most worthy of mention as explaining the cause of regimen that has for its object the amelioration of sundry chronic ailments by the rational and systematic employment of a diet composed almost exclusively of fruit. The salient facts relating thereto, being pertinent and timely, are none the worse for repetition.

The so-called fruit cures are among the most useful of the applications of bromatology to medicine, and the direct use of figs, cherries, greengages, currants, raspberries and of strawberries has long been in repute with some European plague physicians. Van Swieten is said to have recommended in special cases the eating of twenty pounds of strawberries a day. He also reports a case of phthisis healed by strawberries, and cites cases in which maniacs regained reason by the exclusive use of cherries as an aliment. Hoffman (Fred.), Richter and Bergen report analogous cases.

According to Geoffroy ("Materia Medica," Paris 1750, Vol. I, p. 52), Forestius has seen inveterate diarrhea that had resisted all treatment, healed by the sole use of over-ripe medlars. Linnæus, a great sufferer from gout, thought he remedied and lessened its attacks by a fruit regimen. It is within the memory of many men living that obstinate cases of bowel disease among soldiers of the late civil war recovered rapidly on eating peaches, the result no doubt being attributable to the correction of a scorbutic tendency. The dietetic virtues of apples has been also much praised, articles thereon having appeared from time to time in the newspapers; so that anything we might say would only corroborate what has already been given wider publicity. It is, however, to the capital virtues of grapes, which contain nutritive principles necessary to maintain health that we must look for the attainment of determinate results. The landmarks of what may be called botryo-therapeutics, though very old, do not appear to have excited the same attention in our country as in Europe, where special works on the grape cure, mostly in German, give methodic instruction regarding the chemical study of grapes and the clinical observation of their effects.

To mention the therapeutic uses of grapes would be to repeat much of the nosologic tables. Their earliest physiologic effect is the promotion of the secretions and of the excretions, without irritation of the intestinal canal, and their use suddenly breaks up all the errors of nutrition, rapidly reconstructs the blood, exercises a salutary action on the nervous system, and favors the formation of fat. Aside from physiologic speculation, the laxative effect of grapes is superior to the mere purgative mineral waters; for while increasing the excretions a grape diet at the same time increases bodily weight and vigor. The action of this fruit is particularly beneficial in constipation and in hypochondriasis, and is to be recommended as of inestimable value to persons of irregular digestion, who have deluded themselves into the habit of taking purgatives. Its virtues as a reparative agent are particularly recommended by its partisans in scrofula, in diseases of the liver and spleen, in hyperemic congestion, in hemorrhoids, in menstrual derangements, in chlorosis and in anemia, particularly that of convalescence. The sequelæ of alcoholism, particularly the stomachic and abdominal troubles, are greatly benefited by the grape regimen. It has been recommended in chronic diseases of the genito-urinary organs, and the aphrodisiac effects of grapes, which **Rhazes** in the ninth century formulated *erectionem augmentat*, have been turned to advantage in treating impotence, and even in breaking up the bromid habit in obstinate insomnia when all other means had failed.

Lately the appendicitis craze being a subject of much popular concern, many people could not be induced to eat grapes, owing to the mistaken belief that the seed would lodge in the vermiform appendage. So fixed indeed is this delusion that many grape growers felt the injury to their crops, which they were obliged to feed to hogs or let rot on the vines.

As a matter of fact the danger from a grape stem or seed lodging in the appendix is no greater than that arising from other articles of food, and there is no evidence to show that grapes have anything to do with causing appendicitis. On the contrary, a grape diet is one of the best prophylactics and correctives of the diathesis causing that form of phosphatic deposit in the vermiform appendix erroneously thought to be a grape seed. Late hospital records of nearly a thousand necropsies, in which the appendix was examined, failed to show the presence of a grape seed, and impacted feces, containing large quantities of grape seed have been observed to cause no interference with the diverticulum. Moreover, an examination of the health statistics of Chicago show that during the months of the grape season there is a notable diminution in cases of appendicitis, and it is stated by **Rosse** that during a considerable residence in Southern Europe and in California, where grapes are used extensively both as food and medicine, he has never heard of a case of appendicitis. Moreover, it is not necessary to swallow grape seeds while eating the pulp.

Notwithstanding the high authority of his holiness the Pope, in extolling the wholesomeness of fruit, like many other good things in connection with the healing art, the fruit cures have their contra-indications, and if applied indiscriminately may even do harm. The grape cure is considered of doubtful efficacy in the uric acid diathesis. Its use is contra-indicated in chronic tuberculosis and in hemoptysis, unless the digestion is good, but some authorities think it of great utility in pulmonary lesions. During menstruation and in hemorrhoidal bleeding the cure should be interdicted, and it is never to be employed in pregnancy and nursing.

In the present state of our knowledge of the subject we may not look for the immediate dissipation of popular error regarding grapes, nor for the establishment of rural stations such as are found abroad; yet it is earnestly to be wished that the foregoing remarks may cause the more frequent appearance of fruit on the tables as a wholesome accessory, and bring to notice a method that may be employed either as a principal or adjuvant resource of treatment in a wide selection of cases with the happiest results.

ETIOLOGIC THERAPY ON EXPERIMENTAL BASIS.

At the Fifteenth Congress for Internal Medicine, held in Berlin from June 9 to 12, this year, **Behring** made some remarks concerning the therapy of infectious diseases that contain points and suggestions of great importance (*Centralb. f. allg. Path. u. Path. anat.*, Bd. viii, No. 14, p. 587). **Behring** first speaks in very discouraging terms of the therapy of the pharmacopeia. His theory of the etiologic therapy of infectious diseases is then explained in the following manner.

Every living organism contains a number of valuable means of protection as well as of cure. These are: 1. The curative powers of the elements of the body which are brought into operation in phagocytosis. 2. The eliminating faculties of glandular organs which are in position to excrete solid and dissolved substances from the body. 3. The protection offered the body by the skin and the mucous membranes. These are mechanisms that can only benefit the individual to which they belong. They are not transferable to a second individual that, for the time being, perhaps needs their help more. But the substances brought about by the action of bacteria in the living body are transferable. Whether alexins or the bodies that cause bacteriolysis and processes of agglutination can produce healing, is doubtful. Healing power is as yet surely demonstrated to belong solely to the antitoxins, and up to the present time these are known to develop only in diphtheria, tetanus and very likely the bubonic plague, as shown by recent reports from the Institut Pasteur. The antitoxins that develop in the blood are absolutely harmless for healthy individuals. All the subsidiary effects of the curative sera that still are observed will be removed by means of improved technic in their preparation. BEHRING reports that he is already on the track of the removal from the sera of the cause of the urticaria not infrequently observed after the use of antitoxins.

The various healing sera act as absolute specifics. In all probability it does not concern an "antitoxic substance" but an "antitoxic power" in the blood which is connected in some way with the proteids of the blood. BEHRING compares this power with that connected with a magnetic metal. In immunization it does not concern a chemic change but a change in the physical condition of the serum albumin. This is the probable reason why it has not been possible to isolate the antitoxin in pure form.

The active and passive immunity differ only in their mode of production; in both it concerns the same antitoxin immunity. The earlier disappearance of the passive immunity is due to the fact that the antitoxins introduced into the body are eliminated more rapidly than those formed in the organism itself.

The failures to apply the antitoxin treatment to all infectious diseases depend on the following conditions:

1. The infectious agents of all these diseases are not known.

2. The agents may be known, but not the toxic substances produced by them.

3. The toxic substances known are relatively very weak and these weak substances give rise to very weak antitoxins in the animal body. These facts are particularly applicable to the septicemias and also to tuberculosis. If immunization against tuberculosis is to be expected then it must first be demonstrated that a stronger tuberculous toxin can be produced than the efforts of v. LINGELSHEIM and RUPPEL, though in part successful, have done. BEHRING has only very recently succeeded in isolating a tuberculous poison in such a degree of purity that it could be used for the purpose of immunization. The recent improved tuberculin of KOCH has only a very weak toxic action. It is five times weaker than the original tuberculin and consequently there could only be expected an absence of reaction in the therapeutic use of the improved tuberculin. BEHRING thinks the new tuberculin is far too weak to be used for immunization purposes: he thinks it rather improbable that substances can be isolated from the bacillus of tuberculosis that can be used for the cure of this disease.

OSTEOPATHS ON OSTEOPATHY.

Nearly all the bills introduced by trained lobbyists into legislatures modifying medical practice acts in favor of osteopathy contained clauses (as the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION pointed out) limiting this favoring modification to the system of osteopathy taught by Dr. A. T. STILL of Kirksville, Mo. It now appears that osteopaths untaught by STILL are trenching on his Missouri monopoly, whereupon, in righteous indignation, he has exposed these appropriators of his "science." WILLIAM SMITH (M.D. of the "Royal College of Physicians and Surgeons of Edinburgh," an editor of the *Journal of Osteopathy* and a professor of "Symptomatology and Surgery" in the Kirksville School of Osteopathy) has lately exposed the "National School of Osteopathy" of Kansas City, Mo., in a letter to a newspaper of that city, wherein he claims that this last school sold him a diploma for $150 without any course of study. The Kirksville osteopaths threaten the Kansas City ones with criminal prosecution. A threat it is devoutly to be hoped they will carry out, since, if they demonstrate their charges of diploma-selling, one diploma-mill will be shut up. On the other hand if they do not, the Kansas City set may smash the act legalizing STILL's school on the ground that it is special legislation and creates a monopoly. In either case the people of Missouri will profit. The profession has lately received new light on osteopathy from its recently established organ. In their wandering from the hackneyed limits of the actual to the realms of the mendaciously bizarre, the Kirksville osteopaths excel Madam MOPP, the 18th century bonesetter (JOURNAL, Vol. XXVIII), and even the SWEETS (the notorious hereditary bonesetters of New England). "Dr." WILLIAM SMITH (the aforesaid graduate of the non-existent Edinburgh college whose title resembles that of one of the "schools" of Buchanan of diploma-mill fame) has recently contributed the following case illustrating "osteopathic science." The patient (*Journal of Osteopathy*, Vol. I, No. 1) after being told that no one could do him any good and that it would only shorten his life to move him, was given up to die with that "terrible disease cancer of the stomach." "For three months before his arrival he had passed no urine. During the progress of the disease the patient and his wife mentioned that fact to the attending physician, who explained that the tumor had closed over the tubes leading from the kidneys to the bladder. Nothing could be done, he must pass away. Against the advice of his physicians his wife brought him to Kirksville and at once found that the 'terrible cancer of the stomach' was a distended bladder." Here the distended bladder was relieved by means of a catheter and seventy-two ounces of stale ammoniacal urine was drawn off. In thirty hours, 300 ounces of urine were voided and the patient is in a fair way to recovery."

According to the *Journal of Osteopathy*, STILL is a case of reversion to the old medicine-man—*of the* trance-medium type. He "sees visions at night of future events which are afterward fulfilled." In one of these visions he "discovered the science of osteopathy." The Shaman (or medicine-man of the races that have passed slightly beyond the lower fetichic stage) used to have visions before his patients, whereafter, to quote BURNS:

> "Baith thur disease and what well mend it
> At ance he tells it."

Judging from the case he reports, SMITH is not far behind his chief in "seeing visions." HOGARTH, when he ridiculed Madam MOPP and bonesetting, little thought that her pretenses would reappear in a presumedly enlightened Anglo-Saxon land a century later, thanks to the control of legislators through lax incorporation acts permitting banks to loan money on the wild-cat stock of rupture-cure "systems," and "medical institutes" or "colleges" for the manufacture of osteopaths.

THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

This Association has just completed its seventh annual meeting at Harrisburg, Pa., under the presidency of Dr. W. T. BISHOP of that city. The scientific business of the meeting embraced a wide range of subjects extending from committee reports on the standardizing apparatus for the medical use of electricity to wider considerations of the expenditure of electric energy in therapeutic applications and its special uses in various diseases.

Among the subjects of a practical nature that were considered were the value of electricity in the uric acid diathesis by Drs. ROBERT NEWMAN and J. G. D. DAVIS of New York. Goiter and its treatment by electricity was considered by Dr. CALEB BROWN of Iowa, the chief point made being the easy curability of the earliest manifestations of this affection in young girls and the neglect of physicians in instituting treatment at this stage. An interesting point was raised by Dr. COOVER of Harrisburg as to the value of electricity in impending heart failure. In the discussion it was brought out that the members present thought electrization of *any* nerve trunk, particularly the pneumogastric, unwise, but that any faradic brush battery, or even the severed wires of an alternating house-lighting current of 100 volts made to press lightly on the bare skin would act as a valuable stimulant by reflex action.

The most novel feature of the meeting was the presentation, by Dr. MASSEY of Philadelphia, of a paper on a new treatment of cancerous growths, the essential element of which was the cataphoric injection of mercury, in a nascent condition of its oxychlorid, into the cancer in such massive doses as to cause a death of the cancer cells. It was claimed that this method permitted the minutest prolongations of the cancerous infiltration to be followed by the mercury-laden current, which caused death and absorption of cancer cells beyond the point where all the tissues were killed by the very strong current used.

A paper by Prof. DOLBEAR of Tufts College, Boston, on "The Molecular Effects of Electricity," was most interesting to merely practical ears and was an invitation to wider views of the possible control that may be exerted by electric currents over normal and abnormal nutritive processes.

The list of new officers is as follows: President, Dr. C. R. Dickson, Toronto, Canada; Vice-presidents, Dr. F. Schavori, Connecticut and Dr. Caleb Brown, Iowa; Secretary, Dr. John Gerin, Auburn, N. Y.; Treasurer, Dr. R. J. Nunn, Savannah, Ga.; Executive Council, Drs. Robert Newman, W. J. Morton, W. J. Herdmann, W. T. Bishop and G. Betton Massey.

CORRESPONDENCE.

New Quackery or New Clothes?

BIRMINGHAM, ALA., Sept. 16, 1897.

To the Editor:—To one who takes a little dip into the history of medical quackery (there are all sorts), the methods all seem so threadbare. Each new "boon to humanity" is such a wearying repetition of the last that it would seem nothing new could possibly be developed. Perhaps this is true, but as far as one with a limited education in medical history can see, the present popular plan of the nostrum-vendors and quack discoverers within our ranks, of ignoring the laity directly and preying upon the gullible portion of the medical profession, is no less than a grand glorious inspiration. All quackeries have "worked the profession," but as a *specialty* I believe this is new. Many of us are familiar with the more conspicuous (not more successful) of these gentry, but even with the most suspicious of us in the beginning these quacks are hard to detect. The pages of many of our journals teem with the advertisements of pharmaceutic nostrums, patent and proprietary, some few of slight value or convenience perhaps, but the vast bulk of them flared forth with bright labels and catchy names, differing in no particular from the nostrums offered the laity: Beautiful waters to dissolve stone; devitalizing phosphates of many brands—"jingoine," "hurraho" and the like. There is hardly any doubt that the long humbugged and suffering laity swallow yearly a much larger amount of patent cure-alls on prescriptions from their confiding family physicians than they do of the much decried, open and above board nostrum, whose sole support is the certificate of the elderly female in Oshkosh, who sends her portrait with it to show that she has an honest face. It is not, however, of these I would speak at present, but of the well disguised commercial gentlemen within our ranks. These, according to the letter of code are in good standing; they belong to all medical societies and are so prominent and ever present in the columns of the medical press that one, the least unsuspicious or ethically near sighted, is apt to be overcome by them before he knows it. Why is our army of confiding innocents so large and what convenient remedy (necessarily a nostrum, they would take no other) can we offer them? What Widal's ear marks whereby they may know these germs they fatten?

This army is large because of the state of medical education. A large proportion of the practitioners of the country were educated before there were any laboratories; or in the cheap schools of the present, the degenerate survivors of those old lecture halls. They are deficient in scientific knowledge, especially so in pathology and bacteriology, and their ability to reason along such lines is at the lowest mark. They detest all bother about lesions and the natural history of disease, they dream constantly of specifics and they are perfectly sure that that medical Utopia, where but "given the disease the remedy follows, given the remedy the disease disappears," is somewhere within their reach. Their very souls yearn for something to cure with, and the supply is always equal to the demand.

Our only cure for this state is higher medical education; there is no hope for this gullible class except that with better schools it will gradually grow less and finally cease to survive.

How shall we know these professional perverts? Those who wring tears of sympathy and weak-minded support and dollars from the laity as do the quacks who follow the old beaten paths of homeopathy, mesmerism, patent cure alls, amulets and incantations, cry out that the medical profession damns them without a trial, and so discover themselves; but this poisonous fungus of our own, apes in every particular the wholesome investigator and discoverer and modestly and merely in the line of discussion, exhibits the *endorsements* of the *regular profession.*

There is no greater fallacy than to suppose one must try all fooleries to know them for fooleries. A profession so beset as ours must have other means. There is one sure sign and but one that will always differentiate one of these pretended discoveries from a real one. The real ones are offered to the medical profession to handle, pick to pieces, and prove worthless if they can; the pretended discoveries are always protected from such handling by being kept a *secret*, behind which secret is a *money value.*

The medical man who offers a secret remedy of which he has exclusive control in the manufacture or a share in the profits and by which he enriches himself, differs no jot from one of the horde of nostrum-vendors who live by obtaining money under false pretenses; the only false pretenses by which money is obtained not punishable by fine and imprisonment.

Life is too short to try all these nostrums, and no one but a lunatic would ever think it part of an honest man's duty to attempt it. The burden is on the *discoverer* to free himself from every suspicion of secrecy and commercial interest (those legitimate and copyrighted marks of quackery) before offering his method to decent and intelligent physicians.

This quackery within the ranks is most difficult to discover; it is so smooth and tactful in mimicking the talk of the laboratories; it speaks so familiarly of rabbits and guinea pigs, of experiment number 140 and of control animal number 175, of cell construction and the like; and withal so modestly of its fabulous cures, that the honest general practitioner is sharp indeed if he can always detect the cloven hoof.

But the work of these (pseudo) laboratories is not secret; no indeed, it is merely that this one large brain, ceaselessly at work on all sorts of germ juices (that will sell), can not take time to acquaint the knowing world with what he is doing and how he is doing it. Each batch of his product is better than the last, and although he has little time to make his claims, his statistics vociferate that the death rates of consumption and typhoid fever have turned pale in the face, and that the goal of this benefactor is plainly in sight.

These pretenders occupy much space in our best journals, and even much time in our best associations, are listened to respectfully and treated politely in the discussions, when many, nay, probably a majority of us, know them for what they are: rank pretenders, ostensibly for a place in company with Koch, Pasteur, Jenner and Lister, but really for the notoriety and money there is in it. Probably not one of these loudest has had a laboratory training, or even enjoys a speaking acquaintance with one eminent bacteriologist or pathologist, and yet we sit silent and see them enrich themselves by selling the product of these spurious universal laboratories to our unsuspecting brothers. These wholesale laboratory merchants like good company, and in the most casual manner possible constantly associate and compare their work and methods with the work and methods of real investigators. The consumption quacks speak glibly of Koch's work and then of their own, in a way to suggest that Koch and all real toilers are back numbers. The typhoid fever millennists speak of the Brand method as of an old used-up competitor. The consumption quack does not pretend to work miracles. No, he is most particular in his painstaking efforts to be exactly honest in the report of his work, and that of his colleagues, with this gradually improving remedy. Too much weight, forsooth, is given his every utterance to permit him to say that consumption is ever *cured*, but in all its many stages there is just a steady improvement in from 10 to 80 per cent. of the cases over all heretofore used remedies. *All* the incipient cases, *most* of the second class and *many* in the last stages have had their coughs, expectorations, night sweats and fever stopped; have gained from ten to one hundred pounds in weight and have returned to work, and are keeping it up year in and year out, ten hours a day, without the return of a symptom; but, of course, the manufacturer of this anti-death does not claim a cure. Oh, no! he says he has not had time enough yet, nor patients enough; he is too honest and accurate and scientific to pronounce anything positive until the profession of the entire country have sent him all their patients for a number of years (their well-to-do patients; the stuff won't work on paupers). No, they refuse to blow their own horn; they modestly insist that their statistics must make or unmake them. Possibly, like Simon Suggs, whose legal fame and usefulness rested on his proficiency in hunting up evidence among the busy haunts of men rather than on the distasteful drudgery of studying the legal merits of his cases in the books, these our friends may snatch a few moments now and then from their brain-wearying scientific research to give to the easier pursuit of garnering statistics.

GEORGE S. BROWN, M.D.

A way to Settle the Respective Merits of the "Brand" and "Woodbridge" Treatment of Typhoid.

SEPTEMBER 21, 1897.

To the Editor:—Much valuable space in the JOURNAL has recently been devoted to communications from Dr. Upshur and Dr. Woodbridge, anent the treatment of typhoid fever. What we of the disinterested third party had hoped to find a critical presentation of the merits of the case has degenerated into a petty squabble, redolent with personalities, which redounds neither to the credit of those concerned nor is of benefit to the science of medicine. This fact is much to be regretted. The treatment of typhoid fever is a subject of too vital importance to be even temporarily obscured by the mud with which these estimable and gallant gentlemen have been so assiduously pelting each other. What the profession at large desires is to arrive at the truth of the matter; and the sooner this can be reached the better for medical science and humanity in general.

In all justice, what right has Dr. Upshur or any other man to assume to condemn a treatment which, either right or wrong, he has never even tried? It would seem as if *a priori* reasoning were a trifle presumptuous in the face of the bulk of statistics which Dr. Woodbridge appears to possess. By what right *does Dr. Upshur calmly* wave aside as "*mistaken diagnoses*" the several thousand cases which had been considered as typhoid fever by supposedly intelligent physicians! *Does* he arrogate to himself and the few who shall name the exclusive power of recognizing typhoid fever? Dr. Upshur has never tried Dr. Woodbridge's treatment. Instead of appealing for information on the subject from those who have done so he cites as authority a half dozen men who themselves have never tested the treatment, and yet he and they assume to discredit it without hearing or trial; truly a case in this instance of the "blind leading the blind," for even these "princes of medicine," as Dr. Woodbridge truly styles them, must learn by experience like the rest, and do not acquire knowledge by simple intuition. Dr. Upshur believes that the microscope proves the inutility of the so called eliminative treatment. If Dr. Woodbridge's statistics are reliable, and they must be considered as such until *proof* is given to the contrary, a thousand laboratory conclusions and unfortified suppositions are worthless in the light of the clinical results there demonstrated.

As to Dr. Woodbridge, he has evidently permitted his enthusiasm to get the better of his discretion. The unqualified statements that every case of typhoid fever can be aborted and that it is an affection which need never prove fatal are not supported by even his own statistics. That these same statistics do show a wonderful improvement over those given by the Brand or other method of treatment is none the less a fact. Their rejection is not warranted merely because they do not coincide with our preconceived ideas. Medicine is constantly progressing and possibly the Woodbridge treatment may be a step in advance. At all events, the matter is of such importance and Dr. Woodbridge has already received such strong support that the matter can not be tossed contemptuously aside. Let us have it settled at once and definitely; settled beyond doubt or question. Let there be an end to these recriminations and puerile personalities. Let some medical society appoint a commission of reputable and conscientious men to personally test and report upon the matter. Let Dr. Woodbridge appear before such commission and fully explain his methods, they to be minutely adhered to in the treatment of all patients. Require the symptomatic diagnosis to be in all case to be confirmed with Widal's serum test. Take the cases as they enter hospital, without regard to the age of the patient or the duration of the disease, and treat every alternate patient by the Brand method for purposes of comparison. If the results reached are an improvement over the present methods a grateful profession would not withhold the honors due the originator of the improved treatment. If the method is not what it is vaunted—well, we would be no worse off than at present, and the Woodbridge treatment would be at once and permanently relegated to obscurity.

Let us have this question settled, and incidently stop this useless and petty wrangling.

Very respectfully, M.

BOOK NOTICES.

A Manual of the Injuries and Surgical Diseases of the Face, Mouth and Jaws. By John Sayre Marshall, M.D., Chicago. Philadelphia: The S. S. White Dental Manufacturing Co. 1897. Pages 716.

This book is intended for the class room, and is quite as useful to the general surgeon as to those confining themselves to the surgery of the face, mouth and jaws. The text, although written by a dental practitioner, is essentially a work for the general surgeon, as most of the operations figured in this book will often be undertaken by them. The illustrations are copious and well selected and no fault can be found with the method of the work and the manner in which the subject is presented.

The chapters are as follows: 1 and 2, surgical bacteriology; 3, 4, 5 and 6, inflammation and treatment; 7, abscess; 8, ulceration; 9, necrosis, caries and gangrene; 10, traumatic inflammatory fever; 11, septicemia; 12, pyemia; 13, erysipelas; 14, tetanus; 15, shock and collapse; 16, ligatures, sutures and suturing; 17, wounds; 18, treatment of wounds; 19, gunshot wounds; 20 and 21, fractures of the inferior maxilla; 22, fractures of the superior maxilla and upper bones of the face; 23 delayed union in ununited fractures; 24, dislocation of the inferior maxilla; 25, ankylosis of the jaw; 26, periostitis of the jaw; 27 and 28, necrosis of the jaws; 29, stomatitis; 30, 31 and 32, surgical tuberculosis; 33, 34, 35 and 36, diseases and tumors of the maxillary sinus; 37, diseases of the salivary glands; 38, neuralgia; 39, treatment of trifacial neuralgia; 40 and 41, congenital fissures of the lip and vault of the mouth; 42, 43 and 44, tumors; 45, 46 and 47, cystomata; 48, 49, 50, 51 and 52, carcinomata; 53, mesoblastic tumors; 54, chondromata; 55, osteomata; 56, angiomata; 57, 58 and 59, sarcomata; 60 and 61, odontomata, and 62, retention cysts.

After each chapter is a series of questions for review, especially adapted for students or classes in recitation. The book is a valuable one and will be found extremely useful for students and instructors, and no doubt the general surgeon will find it a handy volume for reference. We regret to see pictured in the book the old Hey's saw, an instrument, by the way, which is scarcely used by any modern surgeon. Although Hey had described it in his book, it had long before figured in Scultetus' "Chirurgeon's Storehouse."

Rheumatism and Its Treatment by the Use of the Percusso-Punctator. By J. Brindley James, M.R.C.S. Second Edition. London: Rebman Publishing Co., Limited. 1897. Pages 39.

This opusculum is devoted to showing the relief sometimes afforded in lumbago, vertigo, hemicrania, pleurodynia, sciatica, by the percusso-punctator, which is really multiple acupuncture. Incidentally the author gives some space to the treatment of sciatica and lumbago by the injection of sulphuric ether, which he warmly advocates in certain cases. He states, after some preliminary remarks, that "dry cupping over the seat of the lesion, I inject with subcutaneous syringe daily ten minims of sulphuric ether. If in the course of a week I find no marked progress, I gradually increase this injection dose up to the maximum of thirty minims. Concurrently with this external treatment I have found it advisable to administer internally, first, at the outset, a brisk purgative; second, a mixture containing 5 grains of salicylate of soda (30 centigrams) in 1 ounce of infusion of gentian, 32 c.c., with 10 minims of chloric ether and 10 minims of tincture of ginger, every four hours. In not one solitary case have I found this prove a curative failure. Usually in two weeks' time my rheumatic patients have found themselves cured. In cases of lumbago and sciatica I have found it work more expeditious wonders still."

While we doubt if every practitioner's experience would be so pronounced as has been that of our author, yet there are many points worth considering in this entertaining volume.

Notes on Pathology for Students' Use. By W. A. Evans, B.Sc., M.D. Chicago: The W. T. Keener Co. 1897. Pages 472.

This book, which is written for students, has been interleaved, and is evidently intended as a recitation book. It has no index. The style of the writer is peculiar. The following are specimens:

Page 206: "In discussing stomach conditions, it is to be borne in mind that the stomach remains in contact with the gastric juice after death, and that therefore punctures, holes, loss of mucosa, etc., may be present, independently of pathologic processes." It might be asked of the author how can a hole be present, or how can the loss of mucosa be present? Again: "The stomach is a large viscus in which substances remain for some hours; therefore violent irritants show their effects markedly here." Here is another involved sentence (page 324): "This organism is essentially an epithelial organism. Its toxin absorbs, producing some inflammatory reaction in the lymph channels in which it travels, and also general toxemia." Now, it would seem to be the toxin which absorbs something. What is it that the toxin absorbs? Furthermore, "when strictures result there is probably secondary infection of the mucosa with other germs. It is prone to wander into the crypts of glands and there lose its virulency sometimes on proper occasions, and sometimes never." Whether it is the stricture or submucosa which wanders into the crypts it is difficult to understand from this sentence.

Page 380: "The parenchyma: Our known technical methods are of very little service in showing cells of the nervous system." The inference is, then, that it is the unknown technical methods that are all right. On the same page we find, "the perverted chemistry in a nerve cell will give expression to symptoms far more promptly than any other structures." Let this sentence be carefully pondered. Page 396: "Anatomy: The meninges are thickened and adherent, especially in its posterior segment." Page 218: "On the peritoneal surface the epithelium again breaks out into greater activity." That the epithelium breaks out will be a novel statement to most pathologists. Page 134: "This protoplasm may be quite granular. Tubercle bacilli can frequently be stained within them, though when they *pick up the bacillus*, the bacillus very promptly loses its power to *take up the stain*." (Italics ours.)

Looseness of statement is characteristic of the book throughout. We regret to see this carelessness of expression because the author has shown a fair knowledge of the subject.

Tuberculosis of the Genito-Urinary Organs, Male and Female. By N. Senn, M.D., Ph.D., LL.D. Illustrated. Philadelphia: W. B. Saunders. 1897. Price, $3 net; pp. 311.

It has been the aim of the author in the preparation of this work to place available clinical material upon an etiologic and pathologic basis and to give due attention to the bacteriology of tubercular affections of the genito-urinary tracts. It is a very fair and complete statement of the existing state of knowledge on the subject-matter of this work. It is intended as a companion-piece to the author's work on "Tuberculosis of Bones and Joints," and as such will add to the already great reputation of its distinguished author. The illustrations are largely original and are fairly well representative of the affection under consideration. The type is large and clear, the paper is excellent, and the book will long remain as an admirable monograph on this subject.

Appendicitis and Its Surgical Treatment; with a Report of Seventy-five Operated Cases. By Herman Mynter, M.D. (Copenhagen). Pp. 303. Philadelphia: J. B. Lippincott Co. 1897.

If there were any doubt as to the great variance of opinion in regard to the treatment of appendicitis, that doubt would have been set at rest by the discussion and papers read at the last meeting of the British Medical Association; and in view of this uncertainty, notwithstanding all the works that exist on the subject, it is well to have a book of this character, which is a careful compilation of the existing opinions on the subject with a record of the author's own cases. The author's classification of the different forms of the affection is admirable and his presentation from a surgical standpoint is unexceptionable. There is a moderately complete bibliography at the end of the volume. The work as a whole constitutes an important contribution to the literature of the subject, although it must be confessed that little new matter has been added. But its manner of presentation is concise, clear and perspicuous.

Transactions of the Sixty-Fourth Annual Session of the Medical Society of the State of Tennessee. Nashville, 1897. Cloth, 300 pages.

The report comprises the proceedings, list of members, constitution and by-laws, code of ethics and numerous papers: "Plea for the Better Care of the Teeth, etc.," "Impure Milk and its Evils," "Antiseptic Treatment of Typhoid Fever," "Vesical Calculi," "Brandt(?) Method of Treatment of Typhoid Fever," "Bovine Tuberculosis," "Antiseptic Midwifery," "The Pregnant, Parturient and Puerperal Woman," "Eclampsia," "Headaches," "Shock," "Are We Doing Our Duty,' "History of the X-Rays, Their Medical and Surgical Application," "Facts and Theories as to the Law of Direction," "Gallstone Surgery," "Extra-uterine Pregnancy," "Drifting Away," "Purulent Conjunctivitis, its Treatment with Argonin," "Constipation and Rectal Diseases," "Duty to the Insane," "Observations in Electro-therapeutics," "The Pathology of Malarial Hematuria," "The Correction of Refractive Defects of the Eye a Branch of the Practice of Medicine," "Antitoxin in Diphtheria," "A Modified Thorner's Mastoid Retractor," "The Abuse of Antipyretics," "Typhoid Fever," "Summer Diarrhea in Children."

Transactions of the Medical Association of the State of Alabama. Cloth, 456 pages. Montgomery, Ala.: Brown Printing Co., 1897.

This volume contains the minutes of the session held by the Society at Selma, Ala., April 20-23, 1897, comprising reports of officers, roll of county societies, etc. The appendix presents 186 pages of "Medical and Sanitary Dissertations and Reports," among them the following: "Endemic Multiple Neuritis," "Sterility of the Sexes," "Puerperal Eclampsia," "Renal Calculus," "Medical Topography and Climatology of Southern Alabama and the Gulf Coast," "Medical Topography and Climatology of North Alabama," "Bacteriology, its Value in the Diagnosis and Treatment of Disease in Alabama," "Importance of the Microscope as an Aid to the General Practitioner," "Shall We Do an Iridectomy in Extracting Cataract?" "Case of Spina Bifida, with Operation," "Morbid Mental Action from a Physiologic Standpoint," "Stone in the Bladder," "Granular Urethritis," "The Necessity of Immediate Operation in Mastoid Disease."

Transactions of the Medical Society of the State of West Virginia, held at Charleston, May 19-21, 1897. Paper, 148 pages. Wheeling: 1897.

The constitution and by-laws of the Society are given, together with minutes of the thirteenth annual session, catalogue of members and the following papers: "Post-graduate Medical Education," "The Etiology and Treatment of Puerperal Eclampsia," "Air and Water as Therapeutic Agents," "Treatment of Chronic Suppuration of the Middle Ear," "Antitoxin," "Acute Intestinal Obstruction," "Ophthalmia Neonatorum," "Ovariotomy in a Child Thirty-three Months Old," "Thoughts on the Causes of Typhoid Fever and Diphtheria," "Cardiac Valvular Diseases," "A Curious Sequence and Complication of Diseases," "The Pioneer Physicians of the Kanawha Valley," "Venesection."

Transactions of the Maine Medical Association, 1897, vol. xii, part 3. Paper. Portland: 1897.

This part contains various reports made at the forty-first annual meeting held at Portland, June 2-4, 1897, also a list of members and the following papers: "The Technique of American Surgery," "Hip-joint Disease," "Accuracy and Honesty of Purpose in the Practice of Medicine," "The Frequency of Errors in Medical Certificates," "Physical Training and its Therapeutic Value," "Two Complicated Cases of Nervous Disorders in the Same Family," "Resuscitation after Submersion," "Addison's Disease," "The Bacterial Features of Typhoid," "The Treatment of Labor," "The Later Results with Diphtheria Antitoxin," "Static Electricity," "New Methods in Disinfection," "Preventive Medicine, or Notes on Sewer Air Poisoning and Sanitation."

Fifteenth Annual Report of the Provincial Board of Health of Ontario, 1896. Paper, 318 pages. Toronto: Warwick Bros. and Rutter. 1897.

This report is admirably arranged and will be of value to anyone desiring information on almost any matter in public health concerning the Canadian management of such matters. The appendix presents reports of cities, towns, villages and townships in tabulated form.

PUBLIC HEALTH.

Diphtheria in Woonsocket, R. I.—Since July 1, it is estimated that over one hundred cases of diphtheria have occurred in this city with a population of a little over 20,000. A report dated September 19, informs us that there have been five deaths from the disease within a week, and from ten to fifteen new cases. The parochial and Sunday schools now hold no sessions. The health officers, the mayor and the board of city physicians were called to joint meeting for the 20th inst., to devise means for stamping out what may yet prove an epidemic.

Chemic Adulteration of Milk.—According to a statement in the *Revue Scientifique*, the chemic adulteration of milk is one of the hygienic factors now to be dealt with. It seems that M. Denigès of Bordeaux, having obtained possession of three samples of yellow powder used by certain milkmen of Bordeaux to preserve their milk, made a chemic analysis of it. This analysis showed that two of the powders were composed wholly of neutral chromate of potash, that the third was a mixture of one part bichromate of potash and two parts neutral chromate, and that the suspected milk had been adulterated with the last substance in the proportion of 0.30 gram to the liter, say five grains to the quart. The alkaline chromates are, in fact, powerful antiseptics, capable, even in small quantities, of retarding lactic fermentation very noticeably, if not of stopping it entirely. But because of the deleterious action of these salts on the organism, the *Revue* calls emphatically for their complete exclusion from food substances, and particularly from milk, of which so many young children drink relatively large quantities.—*N. Y. Tribune.*

Yellow Fever.—Yellow fever is still a mournfully interesting factor in the South. Our record closed last week on September 22. The dispatches since then furnish the following data: September 23, 4 deaths and 9 new cases at New Orleans; 1 death at Louisville, 9 at Edwards, and 1 case at Atlanta. It is reported that at Mobile there have been, up to this date, 38 cases, with three deaths, 19 still being under treatment. September 24, 4 deaths and 10 new cases at New Orleans; 15 new cases at Biloxi, 30 new cases in and near Edwards, and 3 new cases with 2 deaths at Mobile. September 25, 23 new cases at New Orleans; 5 new cases at Mobile; 10 cases at Edwards, and 10 cases at Biloxi. September 26, 23 new cases at Edwards, with 1 death; 17 new cases at New Orleans, 1 more death at Ocean Springs, 1 more death at Scranton, 5 new cases at Mobile, 1 case at California, and 10 new cases at Biloxi. Our record closes with the dispatches of September 27, which cite 2 deaths and 22 new cases at New Orleans, thus making 19 deaths to date in that city, with a total of 160 cases. At Mobile, 1 more death increases the deaths to date to 8, and 3 new cases make the total number of cases 54, of which about 20 are still under treatment. At Edwards, Miss., the deaths to date have been 7, and 12 new cases bring the total up to 188; while at Biloxi 1 more death makes the number of deaths to date 5, and 17 new cases reported, bring the total up to 114.

NECROLOGY.

Edward A. Cason, M.D., died of typhoid fever at La Grange, Ga., September 16, aged 27 years. Dr. Cason was born at Jewells, Ga., Sept. 1, 1870; was educated in the public schools and graduated from the Georgia Military and Agricultural College at Milledgeville; then studied medicine and was graduated from Bellevue Hospital Medical College in 1891. He practiced medicine at Jewells until 1895 when he came to La Grange. He was a member of the Georgia Medical Association.

Marinus W. Seaman, M.D., of Shipman, Ill., at Denver, September 16, aged 67 years. He was an ardent Republican, and attended the first Republican State convention held in Illinois in the year 1856. He was an abolitionist, and in October, 1862, he enlisted in the Union army and was commissioned as second assistant surgeon of the 122d Illinois regiment infantry volunteers, with the rank of lieutenant by Richard Yates, then governor of Illinois. On Sept. 17, 1863, Dr. Seaman was promoted to surgeon of his regiment, with the rank of major. For a time he was surgeon-in chief for the district of Cairo. He served from the time of his enlistment continuously until the close of the war. He then returned to the practice of his profession and continued until about four years ago, when he retired and went to Denver to live with his son. During the war he was for the most part under the direct command of Gen. A. J. Smith.

C. Fumagalli, surgeon-in-chief to the Hospital Maggiore of Milan, with which he had been connected for forty years. His contributions to medical literature have been numerous and important, including a large work on the diseases of children.——Dr. P. Ambrosoli, aged 54 years, physician-in-chief to the same hospital.——J. B. Luys, Paris, age 69 years; well-known alienist and neuro pathologist; author of numerous works on the brain and the treatment of the insane, and one of the first to apply photography to the study of the nervous system, for which he had to invent new processes and instruments. His name has been applied to two regions of gray matter, the corpora Luysii. He lost some prestige in late years by his assertions in regard to the effect of medicines at a distance, having been seduced beyond his depth by the study of hypnotism.——William P. Jones, M.D. Medical College Ohio, 1854, died in Nashville, Tenn., September 25, aged 78 years. He was born in Adair County, Ky., but had resided in Tennessee for nearly fifty years. His prominence made him a postmaster of Nashville, and President of the Medical College there.——Braxton Hicks, M.D., F.R.S., formerly physician accoucheur to Guy's and afterward to St. Mary's Hospital, London, August 28, aged 72 years.——J. C. Howden, M.D., of England, August 17. He was superintendent of the Insane Asylum at Montrose, Forfarshire, from 1857 until last June, when ill-health compelled him to resign.——Ira H. Adams, M.D., West Derry, N. H., September 14, aged 51 years.——L. O. Eastman, M.D., Union, N. Y., September 15.——Horatio A. Hamilton, Perrysburg, Ohio, September 8, aged 68 years, Medical Department University of New York, 1852. Member of the Ohio State Medical Society and the American Medical Association.——John Harrison, M.D., Covington, Ohio, September 15, aged 76 years.——John W. Roberts, M.D., Clarksdale, Mo., September 19, aged 30 years.——G. M. Roberts, M.D., Dade City, Fla., September 19.——Julius F. Schmittle, M.D., assistant house surgeon of the Charity Hospital, New Orleans, September 20, of appendicitis, aged 33 years.

SOCIETY NEWS.

Tri-State Medical Society.—The following papers appear on the program for the meeting at Nashville, Oct. 12–14, 1897: President's address: Carcinoma of the Breast, W. F. Westmoreland, Atlanta. Psychology, J. B. Cowan, Tullahoma, Tenn. The True Physician, His Responsibilities, His Duty to His Profession and the People, John C. LeGrand, Anniston, Ala. A Pessimistic and an Optimistic View of Medicine, Y. L. Abernathy, Hill City, Tenn. A Bouquet of Remedial Agencies, John P. Stewart, Attala, Ala. Treatment of Typhoid Fever, John A. Larrabee, Louisville. Abortive Treatment of LaGrippe, E. H. Richardson, Atlanta. Electro-therapy in Medicines, Louise Eleanor Smith, Chattanooga. A New Mode of Internal Electro-therapy, R. P. Johnson, Chattanooga. Common Sore Throat, James H. Atlee, Chattanooga. Vaccination, Seale Harris, Union Springs, Ala. The Pathology and Diagnosis of Early Phthisis, Llewellyn P. Barbour, Tullahoma, Tenn. Sero therapy in Tuberculosis, Paul Paquin, St. Louis. Importance of Early Recognition of Pleural Effusions, Due to Causes Other than Those Located in the Pleuræ, Louis H. Jones, Atlanta. Abnormal Metabolism, G. W. Drake, Chattanooga. The Subject of Hematology, E. C. Anderson, Chattanooga. Inhibition, Physiologic and Pathologic, J. F. Peavy, Atmore, Ala. The Rational Treatment of Cancer of the Uterus, Geo. Wiley Broome, St. Louis. A Case of Fracture of the Skull, Followed by Basilar Hemorrhage; Trephining; Recovery, Curran Pope, Louisville. The Relation of the Cause to the mmediate and Remote Results of Fracture, R. M. Cunningham, Birmingham. Is Cancer Contagious? E. Mather, Paterson N. J. Stimulants and Narcotics in Obstetrics and Gynecology, R. R. Kime, Atlanta. Surgical Shock, Gilbert I. Cullen, Cincinnati. Cystitis, Its Course and Treatment, W. L. Nolen, Chattanooga. Stricture of the Urethra and its Treatment, William R. Blue, Louisville. Operative Treatment in Enlarged Prostate, H. H. Grant, Louisville. Treatment of Chancroidal Ulcers, A. R. Danforth, Atlanta. Ablation of the Scrotum for Conditions other than Varicocele, W. S. Goldsmith, Atlanta. The Treatment of Cancer of the Rectum, J. M. Mathews, Louisville. Burns and Scalds, G. A. Baxter, Chattanooga, Metatarsalgia, or Morton's Painful Toe, George S. Brown, Birmingham. The Application of Plaster Jacket and Dressings, F. B. Sloan, Cowan, Tenn. Surgery of the Stomach, H. Berlin, Chattanooga. Report of Operative Cases (brain), S. G. Courtney Pinckney, Atlanta. Fracture of the Elbow, B. G. Copeland, Birmingham. Treatment of Fractured Maxillaries, D. S. Arnold, Atlanta. The After-Treatment of Abdominal Operations, Valentine Taliaferro, Atlanta. Epiplocele, Report of a Case, J. W. Griggs, West Point, Ga. Appendicitis, G. Manning Ellis, Chattanooga. The Evolution of the Treatment of the Stump in Operations for Appendicitis, W. D. Haggard, Jr., Nashville, Tenn. Obstetrics, W. G. Bogart, Chattanooga. Some of the Mammoth Ovarian Tumors of Surgical History, A. M. Cartledge, Louisville. Cases of Ectopic Gestation, Operated on by the Vaginal Route, W. E. B. Davis, Birmingham. The Technique in Hysterectomy for Uterine Myomata, W. H. Wathen, Louisville. Hysterectomy, Louis Frank, Louisville. Hysterectomy in the Treatment of Pelvic Diseases, George R. West, Chattanooga. Flap Operation for Atresia Vaginæ, George H. Noble, Atlanta. Meningitis in Children, J. W. Russey, Chattanooga. Mouth Breathing in Children and its Dangers, William Cheatham, Louisville. Injurious Results of Incompetent Refraction Work, Frank Sims, Atlanta. The Causes, Diagnosis and Prognosis of Valvular Diseases, Hazle Padgett, Columbia, Tenn. Rheumatism as an Etiologic Factor in Cardiac Diseases, S. W. Fain, Chattanooga. The Treatment of General Peritonitis, L. S. McMurtry, Louisville. Asylum Reform from the Gynecic Standpoint, Charles A. L. Reed, Cincinnati. Pot Hunter in Surgery, Joseph Price, Philadelphia. Reports of Some Cases of Abdominal Surgery, James M. Black, Knoxville. Abscess of Thigh and Pelvic Cavity, with Report of a Case, B. P. Key, Tracy City, Tenn. How to Elevate the Profession in the Country, T. S. Hughes, Cohutta, Ga. Various Treatments of Epithelioma, M. B. Hutchins, Atlanta. Posterior Urethritis, R. H. Tatum, Chattanooga. Stricture of the Nasal Duct, B. F. Travis, Chattanooga. Chloroform, Cooper Holtzclaw, Chattanooga. Cataract Operations, James Moorse Ball, St. Louis. An Original Method of Preparing Catgut for Ligatures and Sutures, St. Joseph B. Graham, Savannah. Leukemia and Report of a Case of Hodgkin's Disease," A. W. Mardis, Lebanon, Ohio.

MISCELLANY.

To Study the Dental Schools of the United States.—Dr. P. Gires has been officially commissioned by the French Government (July 31) to visit this country and study the workings of our dental colleges.—*Gaz. Méd. de Paris*, August 21.

Correction.—Owing to error in copy in the letter entitled "Improved Method of Cocain Anesthesia" (*vide* JOURNAL, September 18, p. 602), "fine" was used instead of "full" in the last line of the first column, and in the twentieth line of the second column 1.5 per cent. should read ½ of 1 per cent.

An Epidemic of Puerperal Pneumococcus Infection recently occurred at the Nancy Maternity, with various manifestations from pleurisy to inguinal phlegmons, and purulent ophthalmia in one of the infants. The Maternity was disinfected as for puerperal septicemia and the epidemic arrested.

Natural Bitter Water.—W. S. Bogoslowsky, from clinical observations on the action and value of a constant bitter water, draws the following conclusions ("*Transactions* of the Moscow Section of the Society for the Preservation of Public Health," No. VI.): Systematic treatment with Apenta water is especially indicated for constipation produced by atony of the bowels, and it has the advantage that its use does not give rise to subsequent constipation. Its action is more gentle than that of some other bitter waters because it contains less calcium sulphate and no magnesium chlorid.—*British Medical Journal*, August 28.

Appointment.—Dr. Robert Hessler of the Northern Indiana Hospital for Insane, formerly pathologist to the Indianapolis City Hospital, and demonstrator of pathology in the Medical College of Indiana, has been appointed pathologist to the recently completed pathologic laboratory of the Central Insane Hospital at Indianapolis.

C. V. Mettenheimer's Fiftieth Professional Jubilee.—*Memorabilien* for August contains a brief sketch of the career of this popular practitioner, naturalist, author and composer, physician to the Mecklenburg Court, and the recipient of eight orders, including one from the sovereigns of Russia, Greece and Turkey. Two important hospitals owe their erection to his efforts, the Children's Hospital at Schwerin and the Sea-Coast Hospital at Gross Müritz, besides numerous others in which he was actively interested. His name is familiar in medical literature.

Effect of Varnishing the Skin.—Laulanié concludes from experiments on eight rabbits that the physical effect of varnishing is an increase in the emissive action of the skin, while the physiologic effect is an interruption of the digestive function, producing rapid and almost complete inanition, showing a functional relation between the external and internal integument, which is still a mystery to us.—*Ann. de Derm. et de Syph.*, July.

The Proportionate Weight of the Brain in comparison with the spinal cord constantly increases in man from infancy to maturity, while in animals the proportion is reversed; the spinal cord develops at the expense of the brain, as Mies has established by hundreds of observations. Men prove to have a heavier brain in proportion to the spinal cord than wome even in the senile insane, who have the lightest brains of in proportion to the spinal cord, although the average is m times higher in them than in animals. The *Deutsche Med. Woch.* of August 12 contains Mies' communication on the subject to the Berlin Medical Society.

Color Blindness in Japan and China.—The *Lancet* states that a surgeon in the United States Navy reports as a result of an examination in Japan, among 1,200 soldiers, some 1.58 per cent. who were red blind and 0.833 per cent. green blind; among 372 boys, 1 per cent. were red blind, and among 270 girls, 0.4 per cent. Of 596 men in Kioto, 5.45 per cent. showed defective color sense. Dr. Fielde of Swatow, China, examined 1,200 Chinese, using Thompson's wool tests; among 600 men were nineteen who were color blind, but among 600 women only one. It seems that the percentage of color blindness among Chinamen is about 3 per cent. and consequently does not vary greatly from that in Europeans. Dr. Fielde found, however, that fully half the number mixed up blue and green, and that many are quite blind to the perception of violet colors.

Overlying Child.—The evidence in the case against a certain Mary Egan was to the effect that, having a male infant about eleven months old, on the 13th of February, after having been drinking, and being somewhat under the influence of drink, she took the child into bed with her, and in her drunken or semi-drunken sleep lay on the child, and the child died from suffocation. Mr. Justice Hodges of the supreme court of Australia, before whom the trial took place, told the jury to convict the prisoner if they believed the evidence. The jury having convicted her, the learned judge reserved for the considerat of the full court the question of whether his direction was co- rect. Its decision is that the proposition involved was a gether too broad, and that the circumstances disclosed tha charge of manslaughter was not supported. Chief Ju Madden, delivering the opinion, goes on to say, if a wo resolved to do away with her child, and having become somewhat drunk, took it to bed with her with the knowledge that she would probably sleep heavily and overlie the child, doing this apparently innocently, but at the same time with the intent to destroy her child, that would be murder. If, being in that state, she, with the knowledge that she might overlie the child, and against the remonstrances of her friends, negligently took the child to bed with her and overlay it, that would be manslaughter. But here the evidence was that the woman had been drinking and was somewhat under the influence of drink, and having taken her child to bed with her, unhappily overlay it. That was not sufficient to support a charge of manslaughter.

Spasm of the Pylorus in Saturnine Intoxication.—Two instructive cases are reported by Layral which simulated completely the picture of cancer of the stomach in one, and of cicatricial stenosis of the pylorus with dilatation in the other. One was a farmer, the other a carpenter, with nothing to suggest lead poisoning, but the discovery of the gingival line and appropriate treatment cured both. The first case was treated with belladonna, five to six tablespoons of olive oil a day, with milk, followed by copious purgations with senna; the second case with potassium iodid, 1 gram, 50 centigrams a day, with sulphur baths, preceded by the application to the skin of a 10 per cent. solution of hydrochloric acid. He concludes his communication to the *Loire Méd.* by calling attention to the rapid spread of lead poisoning, as the metal is being used more and more in the industries, so that saturnine intoxication may be encountered in every class of society.—*Sem. Méd.*, August 18.

Constitutionality of Privy Vault Legislation.—Chapter 777 of the Public Laws of Rhode Island of April 25, 1889, as amended by chapter 1407 of March 1, 1895, so far as it relates to privy vaults, being the only portion called in question in the case of Harrington v. Board of Aldermen of the City of Providence, the supreme court of Rhode Island holds constitutional, Aug. [illegible], 1897. The first section of the act provides that the Board of Aldermen of the city of Providence may compel any abutting owner or occupant of land upon any street in said city in which there is a sewer to connect the drainage of his land and premises with such sewer, and may direct said owner or occupant to fill up and destroy any cesspool, privy vault or other arrangement for the reception of drainage. It being clearly intended to be an exercise of what is called the "police power," the court does not think the statute unconstitutional because no provision is made for notice to the owner or occupant of premises and no opportunity for hearing thereon is given to the owner or occupant before the passage of the order or direction by the board of aldermen, nor because by the provisions of section 3 of the act, the pendency of an appeal will not affect the power of the board to fill up and destroy the privy vault of such owner or occupant of the premises. Neither does the court deem controlling the contention that a privy vault itself when properly used is neither a nuisance nor injurious to health or comfort. But it emphasizes that the action authorized to be taken must be reasonable and reasonable methods followed.

A Two-dollar Fee for Night Medical Service Visits at Paris.—A disagreement has recently arisen between the prefect of police and the surgeons attached to the night medical service of the sixteenth arrondissement with reference to the payment of fees for which police are liable, the services having been rendered at the request of their officers. By a new regulation the prefecture bases its calculations upon the amount allotted for fees to each quarter, an average for three years being taken, and every three months the whole sum should be divided among those to whom it may be owing. In the Passy quarter, however, the sanitary conditions for the three months, January, February and March, were practically favorable and accordingly the fee worked out at about $4.75 for each visit. The administration considered this too high, and one medical sent in his resignation. With a view of healing the breach prefecture proposed as a way out of the difficulty that made during the first three months of the year in the quarter should be paid for at the rate of 10 francs for every night call.

Literary Notes.—The editor of *Janus* has instituted an inquiry having for its object a uniform system of reporting epidemiologic data. All medical men especially interested in this line of work are invited to communicate with Dr. A. Davidson, No. 30 Morningside Drive, Edinburgh, Scotland.

Dr. A. M. Brown of London has published a book on Molière, in the course of which he argues that the chronic ill-health of the great French dramatist was pulmonary phthisis. Molière was an ordinary *poitrinaire*, suffering from a hacking cough, emaciation, occasional hemorrhages and general debility. If the author is correct, as seems to be the fact from his collation of evidence, he has thrown much light on the inner life of the poet and on the motives that led him to select the medical profession as one of the objects of his satire. Dr. Brown's book, entitled "Molière and his Medical Associations," is published by the Cotton Press of London.

Hospitals.

Speers Memorial Hospital was dedicated at Dayton, Ky., September 23. The building is 185 by 75 feet and cost $75,000.——August F. Brecht, Philadelphia, recently deceased, left the following bequests to hospitals: Samaritan Hospital, $1,000; Orphans' Home and Asylum, $1,000; German Hospital, $500.

Societies.

The following societies have recently held meetings:

Indiana.—Maumee Valley Medical, at Columbia City, September 21; White River District Medical, at Vincennes, September 16; Vanderburg Medical, Evansville, September 21.

Iowa.—Scott County Medical, at Davenport, September 16.

Maryland.—Maryland Medical and Chirurgical Faculty, at Ocean City, September 15 and 16.

Minnesota.—Interurban Medical, at Duluth, September 17.

Missouri.—St. Louis Medical Society of Missouri, September 25.

Nebraska.—The Omaha Medical held its first fall session September 14.

New York.—The Brooklyn Medical, September 17; Onondago County Medical, at Syracuse, September 21; Westchester County Medical, at Echo Bay, September 21.

Ohio.—North Central Ohio, at Marion, September 24.

Pennsylvania.—County Medical Institute, at Scranton, September 14.

Texas.—Briggs Medical, at Waxahachie, September 15.

Idaho.—The Idaho State Medical Society concluded its session in Boise, September 16. Officers for the ensuing year were elected as follows: President, C. A. Hoover of Montpelier; vice-president, G. A. Coffer of Moscow; secretary-treasurer, E. E. Maxey of Caldwell; board of censors, S. L. Gritman of Moscow; E. F. Guoyon of Montpelier; J. V. Givens of Blackfoot.

Virginia.—Richmond Academy of Medicine and Surgery, September 15.

Wisconsin.—Association of Assistant Physicians of Hospitals for the Insane, at Madison, September 20; Sheboygan County Medical, at Plymouth, September 10.

Philadelphia.

THE WINTER COURSE of free clinical lectures at the Pennsylvania Hospital will be given in the new Garret Memorial Building, corner of 8th and Spruce Streets. The first lectures are to be delivered October 2, and they will be continued thereafter on Wednesday and Saturday forenoons from 10 o'clock to 12 o'clock, as usual.

THE CLINICAL LECTURES at the Philadelphia Hospital began two weeks ago.

THE ANNUAL COURSE of clinical instruction by the medical staff of the German Hospital will be given during the winter, commencing October 2.

THE PALATIAL CLINICAL AMPHITHEATER of the Medico-Chirurgical College will be formally opened, October 4th, when the Introductory Lecture of the Fall and Winter Term will be given in it. The Faculty of this school has recently received four valuable accessions to its teaching force. Wm. Louis Rodman, A.M., M.D., of Louisville, has been elected Professor of General Surgery and Clinical Surgery. Charles E.

M. Sajous, recently of Paris, has been chosen Dean of the Faculty and Professor of Laryngology. Dr. John C. Heister of Philadelphia has been given the Chair of Anatomy, general and descriptive, and Dr. Geo. Herbert Meeker has been elected Professor of Medical Chemistry.

THE NEW DENTAL DEPARTMENT of the Medico-Chirurgical College begins its first course on Monday October 4.

DR. HELEN KIRSCHBAUM, who for the past three years has been the resident physician and superintendent of the Maternity Home of Philadelphia, and manager of the Jewish Seaside Home at Atlantic City, has just resigned and has been elected a member of the visiting medical staff of the Maternity Home.

DR. HOBART A. HARE, who has been seriously ill with typhoid fever at the Presbyterian Hospital for the last three weeks, is convalescing and is considered now out of danger.

A BRUTAL MURDER of an elderly librarian was recently committed in this city under circumstances possessing many sensational features. Not the least among these is the statement going the rounds that the district attorney is said to have declared that a man now in prison under suspicion of having committed the crime, is held in spite of there being no evidence pointing to his guilt; while the coroner's physician is studying bloody finger marks and hoping to recognize the criminal by their aid (as in the celebrated case of Puddin' Head Wilson).

DR. H. AUGUSTUS WILSON has resigned from the Chair of Orthopedic Surgery in the Polyclinic and will devote himself to the service in the same department in Jefferson College. The trustees of the Polyclinic passed a series of complimentary resolutions expressing regret in accepting the resignation.

CHANGE OF ADDRESS.

Archibald, O. W., from Jamestown, N. D., to Loury Arcade, St. Paul Minn.

Adams, S. S., from Mountain Lake, Md., to 1 Dupont Circle, Washington, D. C.

Burtch, L. A. W., from Morrison, Ill., to Clifton, Ariz.

Bonnaffou, S. A., from Philadelphia to Williamsport, Pa.

Brener, C. H., from Seguin to Hallettsville, Texas.

Cole, A. B., 1519 M. St., N. W., To 1130 15th St., N. W., Washington, D. C.

Caley, W. B., from 52 W. 35th St., to 5 Park Ave., New York, N. Y.

Collins, T. S., from Globe, Ariz., to Santa Monica, Cal.

De Long, W. H., from Emporium, Pa., to Emporia, Fla.

Dewey, C. R., from Bangor to Mattawan Mich.

Dargatz, G. G., from 960 Main St., to 507 Ridge Blk, Kansas City, Mo.

Haskin, H. P., from Mansfield to 126 Pine St., Williamsport, Pa.

Hessler, Robert, from Logansport to Central Insane Hospital, Indianapolis, Ind.

Harrelson, N. O., from 31st and Main to 703 E. 9th St., Kansas City, Mo.

Hawley, E. A., from 4156 St. Lawrence Ave. to 477 E. 45th St., Chicago.

Klinkowstrom, E. V., from 477 W. Division St. to 493 N. Robey St., Chicago, Ill.

Kurkbride, M. F., from Spring Lake Beach, N. J., to 2212 Green St., Philadelphia, Pa.

Lewis, E. R., from 131 N. Meridian St., Indianapolis, Ind., to 1623 N. St., N. W. Washington, D. C.

Leidy, J., from Narragansett Pier, R. I., to 1319 Locust St., Philadelphia, Pa.

McBride, M. A., from Tahlequot, I. T., to Senior Bexar Co., Texas.

Taylor, P. K., from Mineville to 211 W. 139th St. New York, N. Y.

THE PUBLIC SERVICES.

Army Changes. Official List of Changes in the Stations and duties of officers serving in the Medical Department, U. S. Army, from September 18 to 24, 1897.

Lieut.-Col. Johnson V. D. Middleton, Deputy Surgeon General (chief surgeon, Dept. of California), leave of absence granted is extended one month.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending September 25, 1897.

Asst. Surgeon C. E. Riggs, detached from the New York navy yard October 4 and ordered to the "Newport" October 4.

P. A. Surgeon J. F. Leys, detached from the "Helena" September 20 and ordered to the "Vesuvius."

Surgeon N. H. Drake, ordered to the "Minneapolis," "Columbia" and other vessels in reserve at League Island, Pa.

P. A. Surgeon M. F. Gates, detached from the "Minneapolis" on relief and ordered to the Boston hospital.

Surgeon G. P. Lumsden, detached from Port Royal on relief and ordered to special duty attending officers at Norfolk, Va.

P. A. Surgeon G. A. Lung, detached from the Boston Hospital on relief and ordered to naval station, Port Royal, S. C.

P. A. Surgeon M. S. Guest, detached from the "Vesuvius" and ordered to the "Helena" September 20.

Surgeon F. Rodgers, when detached from Boston navy yard, ordered home and be ready for sea.

Surgeon H. E. Ames, ordered to the navy yard, Norfolk, Va., October 2.

Asst Surgeon M. S. Elliott, detached from the "Indiana" and ordered to the "Porter."

ADDRESS.

THE PROGRESS AND RESULTS OF PATHOLOGIC WORK.

An address delivered at the opening of the Section of Pathology, at the Sixty-fifth Annual Meeting of the British Medical Association, Montreal, Aug. 31 to Sept. 4, 1897.

BY W. WATSON CHEYNE, M.B., F.R.C.S., F.R.S.
PROFESSOR OF SURGERY, KING'S COLLEGE, LONDON, ETC.

[Abstract from advance sheets of the British Medical Journal.]

To trace the history of pathology during the last sixty years would be to follow the science practically from its commencement and to go back to a state of matters which it is almost impossible for us now to realize. Even going back twenty-five years, the changes which have taken place are enormous. At that time the lectures on pathology consisted practically entirely of morbid anatomy—long descriptions, for the most part very accurate and not materially different at the present day, were given of the naked-eye appearances of the diseased parts, but as to how or why these changes were brought about hardly any reference was made. Indeed, very little was known, and when an explanation was attempted it was generally of a mechanical or physical character. At the present time, while of course the changes which take place in disease must be known, the study of pathology is especially directed to the discovery of the mode in which these changes occur and the reasons why they appear. Today it is the etiologic side of pathology which occupies our attention, and deservedly so, for, so far as practical results in the treatment of disease are concerned, the knowledge of the changes produced is of comparatively minor importance as compared with that of the reason why they are set up and how they take place.

The most striking and important advance has been the growth of the great science of bacteriology. Twenty-five years ago bacteriology as a science was non-existent. So far as I remember, bacteria were not even alluded to in our course of pathology, and it was only from Lord Lister that we heard the real facts so far as they were known, or gained any idea of the importance of their study; but even at that time, although his methods of treatment were already yielding brilliant results and saving many lives, and although he had deduced from clinical facts many points in the life-history of bacteria and their relations to the living body, which were only confirmed by experiment subsequently, still the number of actual proved facts was extremely few.

It is difficult for those who have only taken up the subject of bacteriology comparatively recently to realize the absolute blank which it presented even twenty years ago. When I became house surgeon to Lord Lister in 1876, objections of all kinds were urged against the theory on which Listerism was based, some denying the existence of bacteria at all, others maintaining the theory of spontaneous generation; some asserting that organisms were always present in the healthy tissues, others denying that they had anything to do with disease. These objections led me to take up bacteriology, for it seemed to me of great importance to ascertain whether or not, as the result of antiseptic treatment, organisms were absent from the discharges from the wounds. Although at the present time such an investigation would be one of the simplest, yet when I came to carry it out I was met with the greatest difficulties. Practically nothing of the kind had been done before, and all the means of investigation had to be devised. Methods of staining bacteria had not been introduced, we had no oil immersion lenses, and I very soon found that by looking at discharges from wounds containing leucocytes, granular matter and débris with dry or water immersion lenses, and without substage condensors, no satisfactory result could be arrived at. Hence I came to the conclusion that attempts must be made to see whether organisms grew in suitable fluids inoculated from the discharges. Here again everything had to be devised. A suitable pabulum, methods of sterilization, of inoculation and of incubation had to be worked out. A large amount of time was spent in getting over the preliminary difficulties, and after a satisfactory method had been found, much labor had to be devoted to preliminary questions, such as spontaneous generation, morphologic characters of bacteria, their presence or absence in the living body, conditions of growth, and so on.

A great advance which followed soon afterward was the remarkable research by Lord Lister on the bacterium lactis, in which he devised a method of separating bacteria by fractional cultivation, which resulted in the separation of the bacterium which causes lactic fermentation from other organisms. By this research, apart from the method, a great step was gained in the proof of the specificity of a particular bacterium, both as regards morphologic characters and chemic action.

Then came Koch's work on infective diseases of wounds, and the publication of his methods of staining and examining bacteria and of cultivating them on solid media, and this work is at the foundation of all modern bacteriologic research. From this period the investigations have branched off in two directions: 1, almost all the infective diseases have been investigated for parasitic organisms, and in a large number the causal agents have been identified; 2, researches have been carried on tracing out the life history and functional activity of bacteria, and in ascertaining what occurs in the body when organisms or their products are introduced.

From the latter point of view we come to another great landmark in the study of bacteriology, namely, Metchnikoff's work on phagocytosis, a theory which has proved a most suggestive working hypothesis, leading to many of the researches which have given bacteriology its present position.

Many problems remain unsolved. In tuberculosis, why is it that in one part of the body we have a slow growing lupus disease, and in another part, perhaps of the same body, a rapidly developing tuberculosis? None of the explanations usually given, such as differences in the structure or resisting power of the tissues affected or of the individual, differences in the virulence or activity of the organism, etc., seem to furnish sufficient explanation. And the same problem is apparently presented with regard to the bacilli of diphtheria, in that we may have in one case a true diphtheria, in another a membranous rhinitis, while in a third, although the bacilli are present in the throat, the individual may be apparently healthy.

Another very remarkable problem is presented by the results which follow free incisions into tuberculous tissue. An incision is made into the abdominal cavity, masses of tuberculous tissue and tubercle are found scattered over the peritoneum, nothing whatever is done, the wound is stitched up, and yet in many cases the patient, who up to that time has been going steadily down hill, begins to pick up, and the disease may come entirely to a standstill. This phenomenon is not limited to peritoneal tuberculosis. When I was a student, the tuberculous nature of what are now recognized as tuberculous diseases of the bones and joints was then only suspected, and was not generally accepted by the medical profession. At that time Lord Lister, under the impression that these diseases were of a simple inflammatory nature, and having observed the improvement which often followed free incisions into chronically inflamed tissues, began as an ordinary line of practice to make free incisions through the thickened synovial membrane of tuberculous joints with the view of relieving tension, which he looked on as the chief cause of the continuance of the trouble. Nothing else was done, the joint was not even washed out, nothing was taken away, and yet in a considerable number of cases so treated improvement began from the time that the incisions were made; the patients lost their pain, the wounds gradually healed up and the disease subsided. Even in cases in which the results were not so satisfactory it could as a rule be noted that, although the swelling continued in other parts of the joint, and although the disease began again after a few weeks as vigorously as before, yet for a time at least the thickening disappeared in the neighborhood of the scars, showing that there at any rate temporary benefit had occurred. What possible explanation can we give of such a result? The older surgeons used to speak of "setting up a healthy action in the part," and were quite satisfied with that statement. Such a view is too vague for us nowadays, but may there not be here a possible working hypothesis which if followed out might throw light on this matter? May not the occurrence of healing processes at one part influence in some way or other morbid processes in the vicinity?

Again, what is the meaning of a chronic abscess? How is it that the tubercle bacilli at one time produce a quantity of tuberculous tissue, at another a cheesy mass and at another a chronic abscess?

In connection with the pyogenic organisms also we have many problems. How is it, for example, that after an abscess is opened antiseptically suppuration at once ceases? If instead of opening the abscess antiseptically a poultice be applied, suppuration goes on and may be very profuse. But if it be opened at a time when there is free fluctuation and when it is beginning to point, and if the necessary antiseptic precautions be taken and proper drainage provided, no more pus forms, and yet when the abscess is opened it is found to contain living pyogenic organisms. We can easily understand that the subsidence of the fever and general disturbance is due to diminished absorption of toxic products. But why do not these living pyogenic organisms keep up the suppuration? and why is it that after two or three days one may fail to obtain any cultivations from the serum which escapes from the wound? If the inflamed part be opened up antiseptically, however, at an early period, just when pus is beginning to form, there is not always the same complete absence of suppuration, although it seldom goes on to any considerable extent.

Again, an operation wound becomes septic and one naturally opens it up freely and establishes drainage; but here suppuration does not cease at once in the same typical manner as in the case of an abscess which has existed for some days. The old surgeons used to speak of an abscess being "ripe," and they allowed it to remain unopened for some days until it was pointing. They found that if they opened a deep abscess early suppuration went on and was apt to extend. No doubt a variety of causes led to this dictum; they did not provide proper drainage; they introduced other and more vigorous organisms at the time of operation and afterward, etc.; but do not the facts seem to indicate that, as regards the cessation of suppuration, there is some ground for this idea of ripeness. Is it possible that when the abscess has attained a considerable size and the tension of the pus in it is great the sudden release of the pent-up fluid may lead to such a pouring out of serum containing antitoxic substances as to absolutely destroy the organisms present, while, the case being treated antiseptically, no fresh organisms can come in to take their place? And yet I can hardly think that that is the whole explanation.

Although it is in the department of bacteriology that the most striking advance has been made, great progress has also gone on in pathology generally, in a considerable number of cases no doubt stimulated by the results of bacteriologic research, and more especially by Metchnikoff's work. The subject of inflammation has had much attention paid to it, although I can not say that to my mind it has been made any clearer. The tendency now appears to be to regard inflammation as the natural effort at repair after injury. At one time this was the view held by surgeons, and the doctrine was that inflammation was essential to healing, and in the description of healing by first intention it was stated that a red blush occurred around the wound, not so severe, however, as where suppuration takes place, and that without this red blush the edges did not adhere. When antiseptic treatment was introduced it became evident that no inflammatory blush or other sign of inflammation was necessary for healing by first intention; in fact, it was found that wounds healed best when no visible signs of inflammation was present. I have, therefore, always taught that inflammation and healing are two different and, indeed to some extent, antagonistic processes, and that although in every wound the tissues in resenting the injury show the early stage of inflammation, yet if no organisms be admitted the inflammatory phenomena soon pass off, and where there is destruction of tissue a second process, namely, that of repair, begins. I still look on inflammation as the mechanism which gets rids of noxious agents or neutralizes their effects, and on the healing process as that which repairs defects, whether they are caused by injury and associated with inflammation or not. In fact, inflammation must be followed by repair if recovery is to take place, but repair need not be preceded by inflammation. The difficulty arises from the close association of the two processes, both of which have to do with the growth of cells, and from the fact that repair follows as soon as the inflammation begins to subside. Hence, under the microscope, except in cases of acute suppurative inflammation, one sees the two processes at work side by side, and it is not a matter of surprise that they should be confounded.

When Cohnheim first published his observations on the *emigration* of corpuscles, it was thought by many that the leucocyte was everything and did everything, but it was soon evident that other cells of different origin must be taken into consideration. When Metchnikoff's theory of phagocytosis first came out some of those who adopted it assumed that all wandering cells were phagocytes; but here, again, further investigation has shown that cells differ greatly as regards their phagocytic action. I think that a good deal of the confusion of these processes arises from the fact that expressions involving a teleologic argument are becoming very common, more especially with regard to the protective arrangements of the body. On the idea of an acting intelligence on the part of the cells, the two processes would naturally go together; but, looked on as the simple effect of an injury, they should, I believe, be regarded as independent, and the less and the shorter the inflammation the better and quicker the healing process.

A very remarkable thing in connection with these advances, especially in experimental pathology, is the enormous direct practical benefit which has already resulted to the human race; and it is sufficient answer to the antivivisectionists who oppose the use of intelligence and observation and experiment, to point to the saving of human life and the relief of suffering which has taken place in the last few years. Since Pasteur's experiments on spontaneous generation were published remarkable results have been attained in treatment as the result of experimental pathology.

Scientific efforts to arrive at the truth are necessarily slow and must be carried on without any regard to possible ultimate practical results. When the earlier investigators studied the phenomena of electric action they could have had no idea of the revolution which this study of electricity would effect in the history of the world. When Pasteur resolved to test the theory of spontaneous generation, it did not seem likely to lead to any beneficial result; indeed, his friends tried to dissuade him from entering into what was apparently a useless investigation, and yet what numbers of human lives have been saved as the result of that work and what incalculable benefit has accrued. It is greatly the fashion with the opponents of experimental research to demand a single instance in which an experiment has led to the discovery of a means of cure; but in no department of science has a single experiment of itself alone led to the practical result. The final observation which led to the practical result has been built up on numerous and laborious preliminary investigations and observations. And similarly, in regard to the cure or prevention of disease, the final trials on man have been led up to by numerous preceding observations and experiments. If these deluded people had their way, the result would be that experiments would be limited to man, and everyone to whom a new idea occurred would apply it without any previous investigation—surely an appalling prospect, whether for physician or patient.

The practical results already obtained affect diagnosis, prophylaxis and treatment. The diagnosis of many parasitic diseases has now been rendered certain and easy by searching for the causal organism, and I need only instance such diseases as diphtheria, tuberculosis, malaria, anthrax, gonorrhea, etc. It is not only by the discovery of the parasite that diagnosis is assisted, but also by other effects of the organism, such as the sort of changes set up in the tissue, the reaction to products of the organism, for instance, tuberculin and mallein, etc. If no other practical advance had resulted from bacteriologic work, the possibility of establishing a definite diagnosis in obscure cases is surely a gain of the utmost importance.

The greatest of all the advances, because so wide-reaching, has been in the prophylaxis of the disease, especially in the prevention of septic disease after operations, as brought about by the discoveries of Lord Lister. By these discoveries the occurrence of sepsis in septic wounds are much diminished and numerous lives are saved, not only in this way but also by the fact that the Listerian treatment permits the performance of many life-saving operations which could not otherwise be attempted.

Lastly, I may refer to advances in the cure of disease. In the case of diphtheria there can be no question that the antitoxin is a most potent curative agent and that used in the early stages it is almost certain to cut short the disease. As regards tetanus, the evidence in the case of animals is absolutely convincing, but in patients suffering from the disease the effect is not certain, probably because we have to do with an acute illness, which runs its course before the serum has had time to act. The same may also be the case with the antistreptococcic serum, although I have great doubts of its value as a curative agent. In other instances, such as plague and snakebite, we may apparently look forward to a cure; and researches are being carried on with regard to pneumonia which may lead to valuable results; nor must I forget to mention Pasteur's system of inoculating cattle against anthrax. What are we to say about the new tuberculin? We all know how careful an observer Koch is, and the fact that he looks on it as a valuable remedy is to my mind sufficient to make it necessary to give it a careful and hopeful trial.

But it is not only in the direction of bacteriology that advantage has resulted from pathologic research. Look at the advances in treatment from the use of organic fluids. As the result of observations on man and researches on animals as to the effects of excision of the thyroid gland attempts were made to transplant the healthy thyroid gland into animals and patients in whom it was absent and following these attempts the use of thyroid extract has ultimately come to be a recognized method of treatment. There is, perhaps, nothing more striking in medical treatment than the rapid and remarkable improvement in cases of myxedema from the use of thyroid extract.

I might enumerate many other instances of direct benefit from pathologic research, such as the advances in the treatment of tuberculous diseases of bones and joints as the result of better knowledge of the nature and distribution of the disease, the treatment of appendicitis and the investigations on peritonitis and diseases of the appendix, the more complete operations for cancer following fuller study of the mode of spread of the disease, and so on.

But while pathologists are thus working out problems which affect the general well-being of mankind and the solution of which can be no personal gain to themselves, is it too much to ask mankind to furnish the means for such research? The English are looked on as a thoroughly practical people, and yet it is a very remarkable thing that England is almost the only country which does not realize the importance of scientific research and the result is that in England, with very few exceptions, men who might otherwise have thrown much light on these matters are compelled to turn their attention to practice in order to make a living. Unless work of this kind is done how can we hope to advance with any rapidity in the treatment and cure of disease? The surgeon or physician must wait till the information of which he is urgently in need has been acquired for him by the pathologist. Such apathy can surely only be the result of ignorance. A rich man affected with an obscure or incurable malady can not understand how it is that he fails to obtain the definite opinion or the relief which he so earnestly desires and for which he is prepared to pay any price. Surely if he understood the meaning and importance of pathologic research and that the practicing physician can only apply and carry out what is taught by the pathologist, he would bestir himself to aid research in order to gather information which might be of much use to him and others.

EXPERIMENTAL BASIS OF THE DIETETIC AND MEDICINAL TREATMENT OF HYPERACIDITY AND GASTRITIS.

Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY JOHN C. HEMMETER, M.B., M.D., Ph.D.

CLINICAL PROFESSOR OF MEDICINE IN THE BALTIMORE MEDICAL COLLEGE; CONSULTANT TO THE MARYLAND GENERAL HOSPITAL.
BALTIMORE, MD.

Boas, who first used the finding of fragments of mucosa in the vomited matter and gastric wash water for diagnostic purposes, attributed great importance to this way of finding out the real state of the mucosa. He held that, in certain conditions of suppressed secretion, the differential diagnosis between a possible neurosis and a genuine gastritis with a glandular atrophy was only possible by examination of such pieces of mucosa. Rosenheim, Boas and Julius Friedenwald, *Med. News*, June 22, 1895, emphasize the value of qualitative and quantitative testing of rennet zymogen to differentiate between chronic gastritis with glandular atrophy and carcinoma on the one hand, and nervous dyspepsia and secondary gastritis on the other. However, Ewald and also Einhorn have asserted that absolute deficiency of rennet zymogen is not pathognostic for atrophy, therefore it would indeed seem as if a certain diagnosis could only be made by a small piece of mucosa.

Is there any clue which can be derived from these pieces regarding the state of the mucosa in the secretory disorders? This I will try to answer in the following. Hayem, to whom we are indebted for the best histologic investigations of the gastric mucosa, emphasizes that the individual elements of the mucosa, gland ducts, superficial epithelium and interstitial tissue can become diseased in a variety of ways; the various portions of the stomach fundus, pylorus and cardia may exhibit different affections; and finally the mucosa may at different parts show different phases of disease. He distinguishes a parenchymatous and an interstitial gastritis. First the parenchymatous:

1. *Gastrite parenchymateuse hyperpeptique chloro-organique.*—Under this he has two subclasses: *a*, *d'emblée*—dyspepsia coming on at once, in the first stage of digestion; *b*, *tardive*—coming on in later stages, in one and one-half to two hours. Under this hyperpeptic parenchymatous gastritis Hayem means, clinically, a hyperpepsia with hyperacidity, and anatomically, degeneration of the principal central or chief cells with proliferation of the parietal border or oxyntic cells.

2. *Gastrite parenchymateuse muqueuse*—"gastritis mucipara," by which he means a mucous degeneration, a process taking place principally in the vestibules to the gland ducts (which are lined with columnar epithelium), and corresponds to the Schleim Katarrh of most German writers. This is associated with hyperpepsia and subacidity.

3. *Gastrite parenchymateuse atrophique*, which signifies anatomically the total atrophy of the glands without interstitial processes, and clinically, anacidity or achylia. The interstitial forms he separates into two classes: those in which the round cell infiltration, and those in which the sclerosis, *i. e.*, connective tissue proliferation, predominates. These processes are described as occurring purely as such, or mixed with forms of parenchymatous gastritis, and as leading to sub- or anacidity. In order to bring my results in critical consideration with those of Einhorn, I have adopted his classification of the anatomic conditions found in these fragments. There is, however, one objection that can be urged against it, and that is the apparent fact that he has based his system on conditions of the gland tubes and interglandular tissues exclusively, and mentions the state of the cells only once in six types described. I will therefore supplement his categories by adding the state and condition of the vestibular or alveolar columnar cells (Vorraum Zellen), and the condition and numeric relations of the chief, central or ferment cells (Hauptzellen) and the parietal, border or oxyntic cells (Belegzellen).

1. Normal. Gland ducts and interglandular tissues exist in normal proportions. Columnar epithelium of the surface and that of vestibule normal, with scarce cells showing at their free ends slight mucoid metamorphosis. The average number of parietal or oxyntic cells in six ducts which were sectioned very nearly down the center was twenty-two to forty.

2. Connective tissue excess. Proliferation of connective tissue around the glands, glands and epithelial cells as in normal condition.

3. Proliferation of glands. Under this class I have in nineteen cases been impressed with the probability that there must be three types of this condition:

Type *a*.—In this subtype there is a proliferation of gland tubules. Under the same field of microscope there will be more than under normal conditions, since they are much closer to each other, but the number of central and oxyntic cells are from eighteen to forty-two, or the same as under the normal condition.

Type *b*.—Increase of oxyntic or parietal cells with normal number of gland ducts. Here there seems to be no proliferation of the gland ducts, the connective tissue and the ducts bear the same relation as in class 1, but the anilin staining, oxyntic cells may be so increased that they lie in juxtaposition, giving the whole duct the appearance of a peptic duct of the dog; the number may reach seventy in one duct. The oxyntic cells are increased in size; the nuclei stain very dark.

Type *c*.—Increase of the number of ducts in which the number of oxyntic cells appear normal in size and number, and in the same fragment or section portions of mucosa in which the ducts are not augmented, but the oxyntic cells are increased in number and size; this third is then, it would seem, a combination of types *a* and *b*. When there are many oxyntic cells above the normal, the entire gland duct assumes a tortuous or elongated shape. It seldom extends down into the mucosa in the same plane, therefore it is very rare that a section will strike down the middle of a duct. Generally the counts in six ducts struck fairly along the central canaliculus are taken as an average.

4. Incipient atrophy. To the same field under the micrometer there are fewer glands than normally present. They appear shrunken and smaller, and at the same time the spaces between the glands are larger than normal, owing to an increased connective tissue formation; the latter is thickly invaded as a rule, with small round cell infiltration.

5. Atrophy. In complete atrophy there are only remnants of glands left, a few degenerated cells lying in empty circular spaces where glands had previously existed; there is also a diffuse round-celled infiltration.

6. Vacuolization. Round or ovoid vacuoles exist within the glands in large numbers, being the result of mucoid degeneration of some of the glandular cells; this is generally associated with connective tissue proliferation. Vacuoles are present in the gland cells normally and can be seen in the drawings of Kupher and Stöhr. I have also seen them in both longitudinal and cross sections of the gland tubules, but rarely more than two to three to the entire duct. It is conceivable that they may be produced by the process of hardening and imbedding. Some of the fragments obtained from stomachs may show characteristics of two types.

DEDUCTIONS FROM THIRTY-SIX CASES.

In eight *healthy* persons the mucosa fragments were normal in six; proliferation and autodigestion marked in one, which also showed beginning small round cell infiltration between the ducts; connective tissue increase in one. In the first of these cases the examination showed proliferation in one fragment and a normal condition in a second one found in the same wash water.

In eighteen cases of *hyperacidity*, the fragments of gastric mucosa were found apparently normal in four; atrophy of gland tubules and connective tissue increase so that there were fewer glands, but in these few there were contained a larger number of oxyntic cells than normal, in two cases; proliferation of gland ducts with apparently normal oxyntic cells in six cases; proliferation of oxyntic cells, generally without marked increase in the gland tubules, in six cases.

In twelve cases of *anacidity* or *subacidity* the fragment was apparently normal in two cases; proliferation of glands with marked small round cell infiltration was found once. Atrophy in some form was found in the fragments from the nine remaining cases.

In establishing the classification of euchlorhydria and hyperchlorhydria we could not be guided exclusively by the amount of free HCl found after the double test meal used at the Maryland General Hospital and described in the author's book (Hemmeter, "Diseases of the Stomach," p. 111. P. Blakiston Son & Co., Philadelphia, 1897). Thus, a young, vigorous farmer, aged 25, who had never had any disease, showed on repeated examination an amount of free HCl equal to 60 degrees, with a total acidity of 80 degrees. Ordinarily, judging simply from the analysis, such a case would be diagnosed as hyperacidity. However, these cases can be diagnosed justly and accurately when considered together with concomitant signs and symptoms only. Although this case had the large amount of free HCl, there was no starch indigestion, no erythrodextrin, no pyrosis; there were no symptoms referable to the stomach at all, the man was in perfect health.

Another case, a neurasthenic female, had intense suffering from hyperacidity and occasional gastroxynsis, and the amount of free HCl was never over 30 degrees. This case showed hypermotility. The stomach as a rule was empty twenty-five minutes after an Ewald test meal; with my intragastric rubber bag in connection with the kymograph, she showed very frequent and sudden gastric peristalsis of unusual tonicity.

SUMMARY.

Eight *healthy* persons: Perfectly normal in six; *a.* glandular proliferations; *b.* normal in 1; connective tissue increase in 1.

Hyperacidity in eighteen cases: Normal in four; atrophy in two; proliferation of glands in six; proliferation or hypertrophy of oxyntic cells in six.

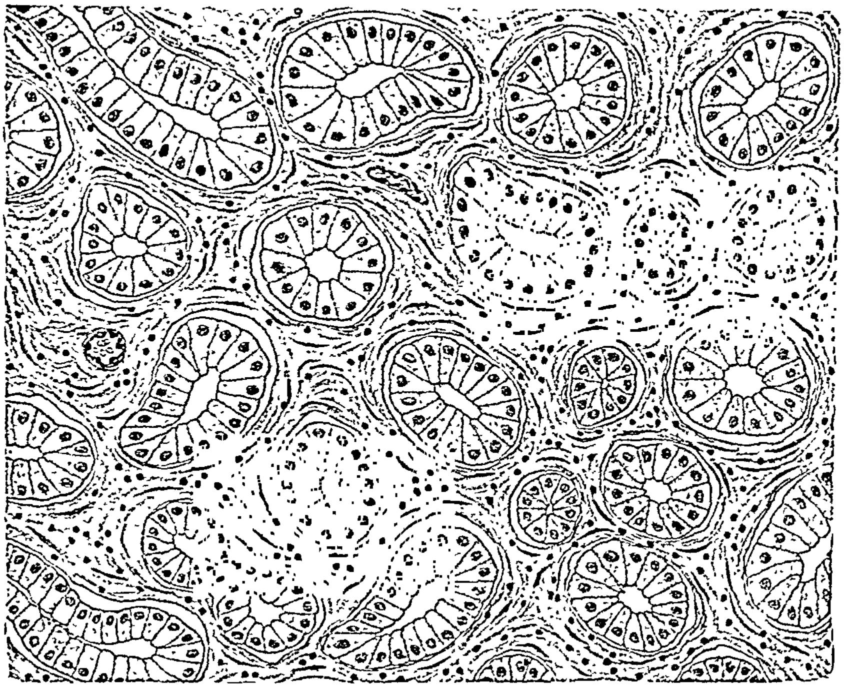
Anacidity or subacidity: Normal in two; proliferation of glands in one; atrophy in nine.

Proliferation, therefore, according to this table is present in two-thirds of these cases of hyperacidity, and atrophy in three-fourths of these cases of anacidity or subacidity. Einhorn does not give any results from examination of perfectly healthy individuals as his cases of euchlorhydria seem to be in patients.

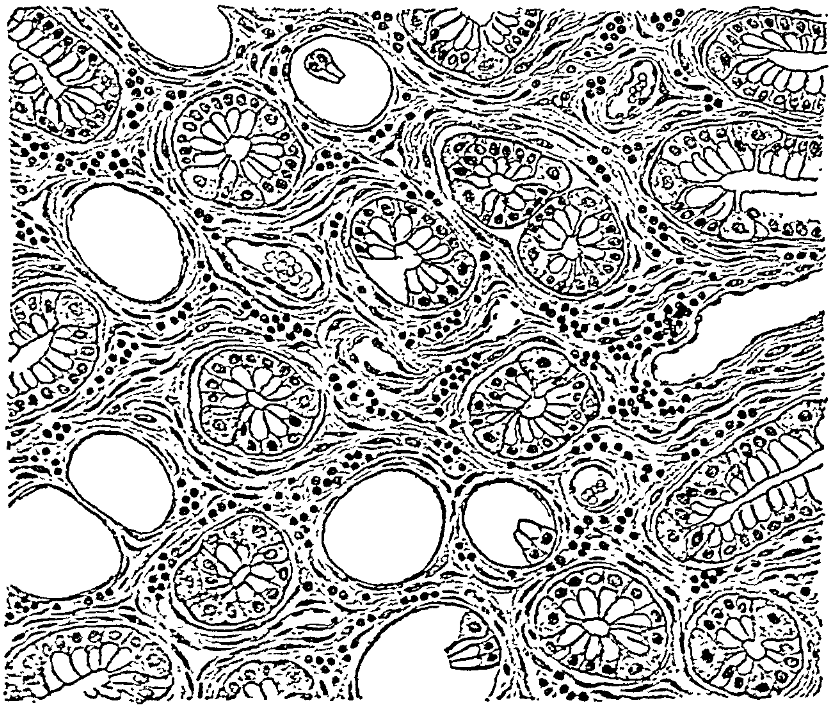
Of his twelve hyperacid cases three were normal or very nearly so, six showed proliferation and three showed connective tissue proliferation. In his cases of anacidity, or rather what he calls achylia gastrica of which there were seven cases, there was atrophy three times, marked vacuolization once, proliferation once, and normal condition twice.

On the whole, judging from Einhorn's results, Cohnheim's, Hayem's and my own, the conclusions seem justifiable that proliferation of glandular elements is present in from one-half to two-thirds of the cases of hyperacidity, and atrophy is present in from one-half to two-thirds of the cases of anacidity.

Adolf Schmidt (*Virchow's Archiv*, Bd. cxliii, S. 478), asserts that the epithelium of the stomach is preserved better than the gland cells in inflammatory conditions of the mucosa. This he says is particularly so in chronic gastritis which forms island-like foci in stomachs otherwise not much changed. My experience and that of W. D. Booker, is not in accordance with this observation (see pathology of simple, acute and chronic gastritis in the clinical portion of Hemmeter's "Diseases of the Stomach"). Although I preserved the stomachs by injecting them with alcohol immediately after death (within twenty minutes), also with formalin and sublimate so that autodigestion was at once checked, my sections showed generally a more serious destruction of the surface epithelium than of the gland cells. At times both are so much altered that it is impossible to say which is most or least affected. It seems in chronic gastritis that new epithelium will be reformed quite rapidly where the old has been lost or destroyed.



Fragment of mucosa showing normal condition of glands; very slight round-celled infiltration. From Hemmeter's "Diseases of the Stomach," P. Blakiston Son & Co., Philadelphia, Pa., October, 1897.



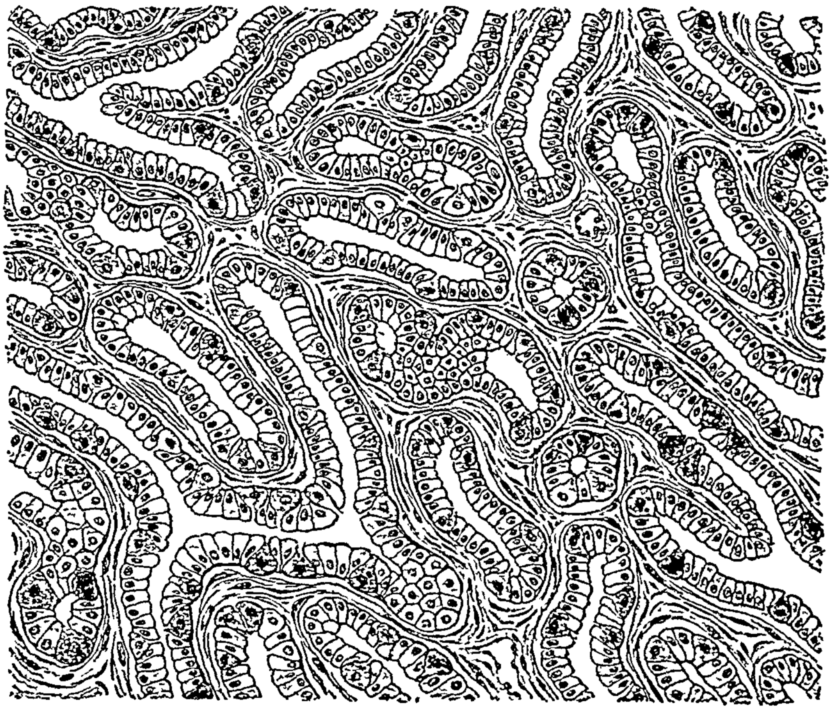
Atrophy and vacuolization of glandular elements; mucoid degeneration of chief or central cells; comparative preservation of border or oxyntic cells; from a case of gastritis acida. From Hemmeter's "Diseases of the Stomach," P. Blakiston Son & Co., Philadelphia, Pa.

In suspected cases of malignant neoplasms fragments of the growth are occasionally found and are of importance in the diagnosis. In carcinoma of the cardia or esophagus they are most frequently found in the lower or side opening of the tube, as it must pass through or over the growth on its way into the stomach; but even in malignant growths of other parts of the stomach, patient searching in the sediment of the wash water will sometimes reward the clinician by the discovery of tumor fragments. The first wash water in the morning, about 500 c.c., should be permitted to settle twelve hours in a conical glass such as is used for the settling of urinary solid constituents, and the sediment should be examined under a low power (about 50 diam.) or the sediment may be more expediently brought down in the centrifuge.

Once I made the diagnosis of carcinoma when no tumor was evident from repeatedly finding involuntary muscle fibers when no meat had been eaten for three days after preceding lavage. It proved to be a broad, flat carcinoma of the posterior wall.

The sections were stained in a variety of ways, principally in the eosin-hematoxylin, Golgi and Bismarck brown stains. The minute communications of the oxyntic or parietal cells with the central duct are best brought out by the Golgi method.

The drawings of fragments found in the wash water of glandular proliferation with glands closely packed and connective tissue diminished, and of glandular atrophy, mucoid degeneration, vacuolization, and small cell infiltration are all explained by the text accompanying the illustrations. These drawings are taken from the author's text-book, " Diseases of the Stomach." We have seen that histologic changes approaching or actually representing pathologic states may be going on in perfectly healthy stomachs. Furthermore, the stomachs of diseased patients may on serial sections show a different pathologic state at different places of the mucosa. Therefore, it must be borne in mind that although the findings in hyperacidity and anacidity appear to be in some relation to the disease, this kind of investigation must not be relied on as representing in a given fragment the condition of the entire mucosa. It represents the state of the location from whence it sequestrated, and that not being accurately known generalizations must be made with caution.



Hypertrophy and proliferation of glandular elements, from a case of persistent hyperacidity.

It is therefore rational to presume that there are at least two kinds of hyperchylia: One which is of neurotic origin and in which the acid elements of the mucosa are not hypertrophied or augmented, and the other in which the neurotic symptoms are absent, or at least not very marked, and in which a decided proliferation of the secreting cells of the gland ducts can be made out. It is conceivable also that in the neurotic type, although there may be no hypertrophy and increase in the number of gland cells at the beginning of the disease, the constant demand upon and stimulation to the increase of acid and ferments may, in the course of the disease, eventually bring about an oxyntic cell, hyperplasia and hypertrophy. Edinger explains the anatomic changes in the spinal cord and nerves by a disproportion of the function of activity and the replacement of nervous elements; an increased activity of an organ leads to straightening of the same and increase in its volume; inactivity leads to a weakening and atrophic state of an organ. W. Roux ("Entwickelungs-Mechanick der Organismen," 1895) uses the expression "each cell gains a living by work, and the more it works the better it is nourished and the stronger it grows." In hyperacidity the elements that come more into play and do more work will increase in strength and numbers and gain supremacy. Dujardin-Baumetz and F. Sohlern (*Berlin. Klin. Wochschr.*, 1891, 20 and 21); Fleiner (Volkmann's Klin. Vortr., 103) and Rummo (*Terapia clin.*, 1892, Nos. 10, 11 and 12), recommended a largely carbohydrate diet in gastric diseases accompanied by abnormal production of acid. We have satisfied ourselves personally, after a very large number of quantative chemic analyses of the gastric contents of healthy individuals after they had taken weighed amounts of pure proteid and pure carbohydrates, that the proteid articles of diet are greater stimulants to the secretion of HCl than the carbohydrates or fats. They therefore stimulate and irritate the secretory layer to a greater formation of hydrochloric acid; this has been experimentally proven to a certain extent by v. Jacksch in children. It is also known that the great variations stated by different authors as to the amount of free HCl that is normal in their localities are explicable by the nature of the various test-meals used by them. The amount of free HCl after the complex test-meal of Riegel and Fleiner in much greater than after a simple test breakfast which contains very little proteid. It must not be overlooked that an exclusive proteid diet causes the formation of excessively large quantities of soluble peptones and albumoses, which undoubtedly have an exciting action on the nervous system and constitute a favorable basis for the development of all kinds of neuroses. Although a diet rich in meat food is [illegible] and [illegible] rect in hyperacidity, careful quantitative analyses of the urine will show that the indican, the ethereal and preformed sulphates are very much more increased under this kind of diet, and that they become reduced as soon as the amount of carbohydrates is increased. Beef, mutton, lamb, venison, fowl and various fishes, undoubtedly relieve the main complaints of hyperacidity for a time. The gastric pain and the pyrosis disappear for a time at least, because the albumin contained in the substances combines with the excess of HCl, but in cases in which a lasting improvement is not affected by these articles of diet, and where the urotoxic coefficient, the amount of indican and aromatic sulphates become increased it is advisable to try a diet in which the proteids do not constitute the preponderance, but at least 50 per cent. of which is composed of fats and carbohydrates.

The following tables show the state of the urine in a case of hyperacidity, both under proteid and under a carbohydrate diet. The case suffered as a rule from auto-intoxication when the proteid food was in excess.

URINARY ANALYSIS.

Case 19.—April 12, 1896. W. M., male, age 35 years, hyperchylia, on proteid diet exclusively; no medicine. Free HCl=48.5 after Ewald test breakfast.

Indigo blue	very strong
Urea	22.712 grams
Uric acid	0.451 grams
Ratio	49.0
Preformed sulphates	1.826 grams
Combined sulphates	0.236 grams
Ratio	7.7

The combined ethereal sulphates and the indigo are present here in great excess; headache and much flatulence.

Case 19.- May 12, 1896. W. M., hyperchylia, Free HCl=59. Mixed diet, containing rice, bread, oatmeal, together with small quantities of beef or soft boiled eggs, and milk and butter. Neutralization with alkalies and aiding the gastric amylolysis with ptyalin at one meal and taka diastase at another.

Indigo blue	very faint
Urea	42.641 grams
Preformed sulphates	4 000 grams
Combined sulphates	0.350 grams
Ratio	11.0

Patient feeling much better, less headache, debility and flatulence. This is an example of twenty analyses, showing that even with an excess of HCl the proteid putrefaction may be considerable and that the symptoms are relieved and the urine shows less of toxins on a mixed diet with treatment by ferments and alkalies.

These are only two examples of a series of eighteen analyses.

It is undeniable that carbohydrates are found undigested six hours after they are ingested, in the wash water from the stomach. This is what one should expect, since if the excess of hydrochloric acid is not neutralized by alkalies, the ptyalin can not act and it is impossible for carbohydrates to be converted into a soluble form, the HCl at the same time producing a pyloric spasm obstructing the passage into the duodenum. Even with a diet almost exclusively of a proteid nature, the alkalies are indispensable, as this food is in itself inadequate to combine with the excess of acid. We advise our patients to take their amylaceous foods in a very finely divided state when possible. Potatoes should only be allowed in form of purée. Beets, turnips and carrots should not be allowed at all. The artificially prepared soup meals (Kufeke's, Maggi's flour, Malto-leguminose) and soups made from aleuronat, and oatmeal flour are in these cases easily digested with the aid of artificial diastase or ptyalin. It is a very important question whether the diastatic ferment of the saliva is destroyed permanently or only temporarily by the excess of hydrochloric acid and whether after its action has been inhibited by the acid it can be restored by subsequent alkalinization. Boas ("Diagnostik u. Therap. d. Magenkrankh.," p. 19) has demonstrated that when saliva is exposed to the action of 0.15 per cent. HCl for one hour its action can be restored by alkalinization with bicarbonate of soda. In hyperacidity the percentage of acid reached is 0.2 per thousand of HCl; in severe cases 0.4 to 0.6 per thousand HCl. We have made a large number of experiments with the effects of hydrochloric acid on saliva, both with artificial test-tube experiments as well as experiments from stomach contents of patients suffering with hyperacidity, and have found that, although Boas's results are in the main true, the action of ptyalin after it has been exposed to an acidity of 0.3 per thousand for forty minutes can not be restored to the same efficiency it showed before it was subjected to the action of the acid; that is, alkalinization restores the action only partially. The conversion of starches by this ptyalin which has been thus detrimentally influenced by HCl takes place only very feebly, in other words, the ptyalin does not recover perfectly, it has been permanently damaged. These experiments have been repeated so often by us and the results have been so constant that they could not possibly be due to accident. They justify us in the conclusion that the internal administration of alkalies in hyperacidity will not restore gastric amylolysis although the distressing symptoms of hyperchylia will be relieved by it. It is therefore necessary, if we wish to aid digestion of starchy foods and not simply relieve the distressing symptoms of hyperacidity, not to depend on restoration of the function of ptyalin by giving alkalies. The employment of artificial ptyalin or diastase is here unavoidable; ptyalin, one-half to one gram (8–15 grains) given fifteen minutes before meals together with alkalies, effectively converts the carbohydrates into dextrose. The more carbohydrate is artificially digested in this way, the less undigested starch will naturally remain in the stomach. We will naturally, therefore, give the preference to a ferment which can in the shortest time convert the greatest amount of carbohydrate into dextrose. We have made a number of experiments with ptyalin and the diastase contained in malt extract, but the most effective agent that we have worked with is a ferment known as taka-diastase. This has the property of being far less susceptible to the destructive action of hydrochloric acid than ptyalin or malt extract. The objection we have to malt extract is that we have to give it in a large bulk to get a very small quantity of diastase. The extract itself contains fermentable sugars which, in some cases of indigestion, may give rise to fermentation in the stomach. Taka-diastase is a substance obtained from a *fungus known as eurotium oryzae*, which is sown on moistened sterilized wheat bran. A growth results which is found, under the microscope, to present peculiar crystals of pure diastase covering the roots of the eurotium which have penetrated the bran. The function of these crystals is to convert the starch of the bran for the nourishment of the fungus. We have employed taka-diastase in hyperacidity and in these rare cases of deficiency of saliva, which are found in the final stages of chronic Bright's disease, and after severe diarrheas. Malt diastase and ptyalin cease acting in the stomach contents much sooner than taka-diastase with a percentage of HCl equal to 0.04 per thousand to 0.05 per thousand of HCl, taka-diastase will still transform more than 50 per cent. of starch into maltose. The following experiments will throw some light on the digestive power of taka-diastase. A starch paste was made from 5 grams of dry arrow-root starch with 500 c.c. of water. Mixtures were then made as follows:

1. 0.5 gram of taka-diastase + 90 c.c. of water + 10 c.c. of starch paste.
2. 0.5 gram of ptyalin + 90 c.c. of water + 10 c.c. of starch paste.
3. 20 gram of malt diastase + 90 c.c. of water + 10 c.c. of starch paste.

These three mixtures were placed at 40 degrees C. and tested from time to time with iodin solution. In periods of time varying from five to eight minutes No. 1 had reached the achromic point, while No. 2 had not reached the achromic point until one hour had elapsed. At the end of three hours No. 3 still gave a bluish violet reaction with iodin. In the presence of 0.015 HCl the action of the ptyalin and the malt extract were arrested, whereas the action of the taka-diastase continued unhindered. We therefore give taka-diastase because of its more effective and permanent amylolytic power, because of its cheapness, and because we are enabled to permit a diet rich in carbohydrate in cases of hyperacidity. The most essential thing in the treatment of an irritable gastric mucosa is rest for a short time, two or three days in every week; no food but milk or thin oatmeal gruel. To give meat and egg with a view to combine with the excess of HCl is only symptomatic treatment. But an amylaceous diet aims at the cause of the hyperacidity, because it is not a stimulant to HCl secretion and does not add to the irritation already present.

In recommending a carbohydrate diet in hyperacidity we are aware that it will generally not be tried until the proteid diet has failed to give permanent relief. The amylaceous diet is to a certain extent antiseptic by its tendency to keep the intestinal chyme acid by formation of lactic acid. The quantitative analysis of indican and ethereal sulphates will keep one posted on the degree of intestinal putrefaction under the two kinds of diet.

It is well known that hyperchylia often occurs in neurasthenia due to uric acid diathesis. The diet must then naturally be adapted as far as is consistent with the gastric function to the uric acid diathesis underlying the whole complication of symptoms (see Diät bei Gicht und Harnsäure dyskrasie, Penzoldt u. Stintzing, Vol. ii).

DISCUSSION.

Dr. C. B. Lowe of Philadelphia—I had the pleasure yesterday of meeting the Japanese chemist, Dr. Takamine, the discoverer of taka-diastase. The remarkable activity of this amylolytic ferment was demonstrated by his placing a few grains in a test tube containing starch paste. After adding it, either in the dry form or as a liquid, the solution began immediately, and in a moment or two the contents of the tube were liquefied and converted. The experiment was a very striking one and demonstrated the great power possessed by this agent in the digestion of starchy articles of food.

Dr. R. G. Eccles of Brooklyn—Did I understand the lecturer to say that maltose would be absorbed from the stomach? I was under the impression that all starchy foods passed into the intestine where it was converted into dextrose by the pancreatic juice and the intestinal secretion. Perhaps Dr. Hemmeter will set me right on this point. I am not sure whether I fully understand his position in reference to the use of taka-diastase in cases of hyperacidity. It would seem to me that most of the starchy foods are not digested in the stomach, although the proteids are acted upon there.

Dr. F. E. Stewart of Detroit—In reference to the question of the absorption of maltose into the blood from the stomach, I would say that I am under the impression that Professor Chittenden found that it was not essential that the starch be entirely converted before being absorbed. Dr. Roberts of London found that the glycogen of the liver is very much like the same products of starch digestion.

Dr. Eccles—I would like to add that I have tried taka-diastase on myself and on patients and have found the results from it to be very good. I therefore was not criticising the treatment but merely desired information upon the physiologic and chemic basis of the method of treatment advocated by Dr. Hemmeter.

Dr. Frank H. Murdock of Pittsburg, Pa.—I have been exceedingly interested in Dr. Hemmeter's paper. I think that the question of hyperacidity of the stomach is one of very great importance and one which offers the most difficulty to me in my practice. If we can have within our reach remedies which, aided by diet, will afford the patient relief, we would certainly all be glad to know it.

Dr. Hemmeter—I must say that I am very much pleased at the discussion of this paper and at the questions which have been asked. One question was whether or not maltose is absorbed from the human stomach and enters the blood as such. I have invented a method of studying this problem by plugging the pyloric end of the stomach in animals; maltose is then introduced into the stomach. The pylorus being closed by the plug, it can not escape into the intestines. Nevertheless, shortly afterward there is no maltose left in the stomach. It is absorbed into the blood through the walls of the stomach. As Dr. Stewart has said, Sir Wm. Roberts has shown that maltose can be absorbed directly into the blood. Not only maltose, but albumose may be absorbed, and I have no doubt that egg albumin may be injected into the intestine and be absorbed directly into the blood without being digested at all. I have been asked how long amylosis will go [illegible] human stomach after [illegible] Now it [illegible] only one thing, that [illegible] acid re stomach contents. If the food stays long enough and there is not too much acid, the starchy constituents will be entirely converted in the stomach. In dilated stomachs, where there is destruction of the hydrochloric acid cells, the digestion of starch may go on for many hours. As soon as the proportion of hydrochloric acid reaches 0.15 then the action of starch ceases. This generally occurs on the average in about forty minutes after the close of an ordinary meal, so that we have this length of time in which to digest the starchy portions of our food in the stomach. If too much work is thrown upon the amylolytic action of the intestinal glands, there may be intestinal failure and intestinal indigestion. Because the amylopsin of the pancreatic juice digests starch and the ptyalin of the saliva digests starch, we must infer that their actions or end products are the same. The cases which Dr. Murdock has mentioned and in which we find alternating states of the secretion, one day hyperchylia, the next achylia, and perhaps in the next few days hyperchylia again, have been termed by me *heterochylia*. In determining the degree of acidity in these cases it is essential to know the amount of proteid in the test meal, because the secretion of HCl is greater after proteid than after amylaceous foods. The condition causing heterochylia can only be cured by correcting an underlying neurasthenia, by good hygiene, proper diet, electricity, baths, etc. Moreover, I believe that in many of these cases, lithemia and gout are at the bottom of the condition of heterochylia. In cases where this persistently exists, the patient may be taught to pass the stomach tube and wash out the stomach for himself with diluted HCl or alkalies as may be indicated, but it is impossible to go into the details of the treatment or give any sweeping advice for the management of such cases.

A STUDY OF THYROID EXTRACTS.

Presented in the Section on Materia Medica, Pharmacy and Therapeutics, at the Forty-eighth Annual Meeting of the American Medical Association at Philadelphia, Pa., June 1-4, 1897.

BY W. H. NEILSON, M.D.
MILWAUKEE, WIS.

Interest in the thyroid body is not of recent origin. As far back as 1856, Schiff demonstrated, by his experiments on dogs, that this gland is an absolute necessity for the maintenance of life in these animals and his deductions have been abundantly confirmed by many observers since that time. After the removal of the thyroid gland a number of characteristic symptoms supervenes, as cachexia, emaciation, apathy and muscular tremor which may pass into convulsions before death ensues. The muscular phenomena appear to have a central nervous origin, for section of the motor nerves prevents them; and it is possible that the trophic changes noticed are also due to perverted nervous influence.

In rabbits, Hofmeister demonstrated that by removal of the gland, leaving the glandules of Gley, life might be maintained. The hair became coarse, the body short and thick, the growth of the skeleton was arrested, the epithelium of the convoluted tubules of the kidneys was altered, and enlargement of the hypophysis cerebri occurred (Crary). In monkeys, these changes occur more slowly than in the lower animals and resemble much the condition developed in man through destruction of the function of the thyroid. The pronounced symptoms of this condition are diminished mentality, muscular weakness, marked anemia, dry harsh skin and loss of hair, with an edema of the subcutaneous tissue which does not pit on pressure. If the individual so suffering receive hypodermatic injections of thyroid extract, or if it be administered by mouth, or even the raw gland be fed him, all of these symptoms, except the anemia, rapidly disappear and he regains his normal condition with the one exception. In the case of dogs, if a small portion of the thyroid gland, after its removal, be grafted into the peritoneum, the evil results are averted. So, too, if a small portion of the gland remain or the parathyroids be left the animal will apparently suffer no inconvenience. Thus it becomes clear that the thyroid body is intimately associated with the normal manifestations of life. There are two views obtaining as to the manner of this association. The one is that the thyroid is a destructive agent, destroying poisonous substances formed in other organs, which if undestroyed would cause the various symptoms found in myxedema. In support of this is given as a fact by some observers, contradicted by others, that products are found in the muscles. blood and urine of animals deprived of the thyroid, which are decidedly toxic in character. The other view is that the cells of the thyroid produce a true internal secretion which finds its way into the blood and plays an important part in producing normal metabolic changes in some or all of the organs and especially of the nervous system. This is supported by the facts that the injection of thyroid extract does good when the function of the thyroid is in abeyance; that microscopically it can be proven that the cells secrete the colloid material, and that it eventually finds its way into the blood by way of the lymphatics; that the beneficial portion of the secretion can by chemic means be separated from the gland, thus demonstrating that it is a secretion of that body. A great deal of work has been done to isolate the active principles of the thyroid secretion. Sigmund Fraenkel has been successful in isolating a substance which is intensely hygroscopic and soluble in water and alcohol, the empiric formula of which is $C_6H_4N_3O_5$, to which he has given the name of thyreo-antitoxin.

Experimenting on animals he found that under its administration there was acceleration of the pulse rate without the fall of blood pressure demonstrated by Schaeffer on intravenous injection of the extract. He also found that the heart of a frog, poisoned by muscarin, which had ceased to beat, was stimulated to activity by a few drops of a watery solution of thyreo-antitoxin dropped upon it. Moreover, he demonstrated that in animals deprived of the thyroid gland with the usual subsequent symptoms, that temporary relief, at least, was given by a subcutaneous injection of a 1 per cent. watery solution of thyreo-antitoxin. He maintains that this substance is an exact chemical and that eventually he will be able to give exact dosage. It is without odor and has a beefy taste.

Baumann and Roos make stronger claims than Fraenkel. By a series of experiments they have been able to isolate a brown amorphous substance which contains the remarkably large quantity of 9.3 per cent., dry weight, of iodin. It has been named thyroiodin. It is almost insoluble in water, only slightly so in alcohol, but easily so in dilute alkalies. The discoverers claim that its administration is followed by the same results as follow the administration of the gland itself, or its extract, in myxedema, obesity and parenchymatous goiters, and indeed that it is more rapid in its action. The amount of this substance varies in different thyroids, large ones only containing a trace of iodin, while in children there is less than in adults. Sheep thyroids are relatively richer in iodin and the maximum amount in humans is found between the ages of twenty-five and fifty. Drechsel has isolated two crystalline basic bodies from the thyroid, one of which is apparently identical with Fraenkel's thyreo-antitoxin. Both of these when administered to thyroidectomized animals exert a beneficial influence and Drechsel suggests that there "may be three separate substances formed in the thyroid which are of value to the body and that corresponding to these the thyroids may exert a threefold effect upon body metabolism." Since Dr. R. G. Murray of Newcastle, England, first used the raw gland in the treatment of myxedema the treatment has been so elaborated and refined and its field of usefulness so broadened that thyroid extract has become a firmly established therapeutic agent, yet not so generally nor so fully recognized as it deserves. From year to year fresh triumphs are recorded for this remedy, not only in myxedema where its first laurels were earned, but in cretinism, acromegaly, rickets, obesity, catalepsy and ichthyosis it has scored signal success. The effects of the remedy administered in proper dose, from 1 to 5 grains of the extract, are to accelerate the pulse and respiration, to increase temperature, to improve tissue metabolism, to cause a greater elimination of urea and a more complete assimilation of nitrogenous products. There is also increased activity of the mucous membrane and skin, and the body weight is diminished, while at first there is muscular weakness. If the dose be too large there is flushing of the face, dizziness, accelerated heart action, with rise of blood pressure succeeded by a fall in pressure, nausea, vomiting, trembling of the limbs and other toxic symptoms of more or less gravity. This toxicity depends somewhat on the preparation, fresh glands being less toxic.

Great care must be exercised in keeping the dose within the limit to the individual, on account of the degenerated condition of the arteries in myxedema; over-stimulation of the heart might result in the rupture of a vessel. During its administration, in myxedema, the joint pains are not relieved, but are often aggravated. Indeed in some cases a synovitis develops, which however yields to the salicylates. Neither is the anemia at all relieved. The remedy should not be given in exophthalmic goiter, as the symptoms are painfully exaggerated. This fact has been mentioned by several and came under my observation in the neurologic clinics of the Milwaukee Medical College. That it has a promptly beneficial effect in myxedema I have had the pleasure of observing; also that the general condition of a patient suffering from acromegaly was improved thereby, and I am now treating a case of psoriasis, but have not had sufficient time to demonstrate its usefulness in this disease. If the discoveries of Fraenkel, Baumann, Roos and Drechsel are all that they claim we have a remedy in this extract which will have an application wherever there is retarded tissue metabolism. This opens up a large field and it remains for us to develop it.

SUCCESSFUL TREATMENT OF CHRONIC (SUBACUTE) RHEUMATISM.

BY GUSTAVUS M. BLECH, A.B., M.D.
MEMBER AMERICAN MEDICAL ASSOCIATION; MISSISSIPPI VALLEY MEDICAL ASSOCIATION; NORTHERN TRI-STATE MEDICAL ASSOCIATION, ETC.
DETROIT, MICH.

Chronic rheumatism, articular or muscular, is considered by the laity an incurable affection. The pain, stiffness, in other words, the disagreeable symptoms of rheumatism, however, drive them into the hands of physicians, usually after every kind neighbor's roots and liniments have failed.

It is this class of cases that the beginner in a community is most apt to get, the older physician's time being taken up with cases of a more or less acute character. Besides, the older physicians have prescribed once or twice for the rheumatic, but no cure being obtained he was dropped.

A few months ago the writer contracted chronic articular rheumatism and pleurodynia. It is therefore but natural that I should have paid some attention to this affection. Summing up my theoretical knowledge of the malady and my experience from actual practice, I think I can say without fear of contradiction that chronic rheumatism is a curable affection, and that every young practitioner could materially benefit his patients if he is willing to devote to them some time and labor.

The trouble is, most of our patients can not carry out instructions with regard to hygienic surroundings, occupation, diet, rest, etc. Chronic rheumatism, while not infrequently met with among the rich, attacks most frequently, however, the poor washerwoman, the bricklayer, and such classes of patients who are compelled to expose themselves to draughts, wet, cold and dampness. That these are etiologic, or at least predisposing agents no one will deny. We know very little and nothing certain as yet about the cause of acute inflammatory rheumatism, but we most certainly know absolutely nothing about chronic rheumatism, save that the above named agents favor the development of one or the other form of chronic, non-febrile rheumatism.

Although this paper can neither deal with either the causes, nor the pathology of the malady under consideration, I beg, for the sake of explaining my standpoint, to make these statements: 1. I am a firm believer in the fact that there are forms of so-called chronic articular and muscular rheumatism which are *never* following an acute attack. 2. That so-called gonorrheal rheumatism is not a rheumatic affection proper, but a complication of gonorrhea, and has no connection with rheumatism whatever. If Dr. Satterlee in his excellent monograph (Geo. S. Davis, 1890) takes an opposite view using "reason rather than empiricism" for his assertions, I speak from practical observation and actual experience among my own patients. That the same facts were observed by the most popular authorities everyone knows. Unacquainted as we are with the real etiologic factors of rheumatism, our treatment must be general.

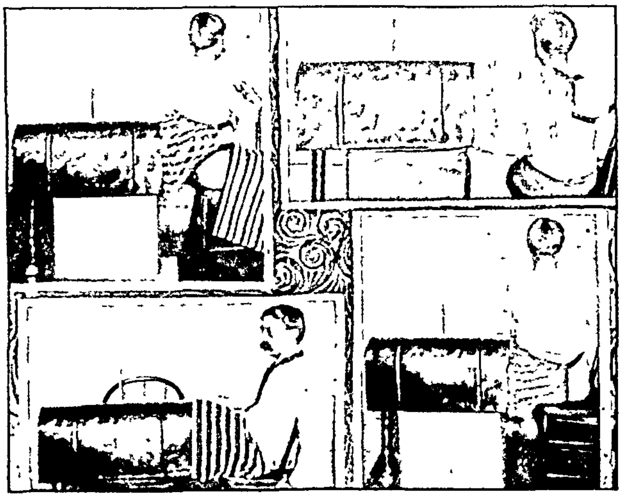
I shall not copy all those rules and regulations as laid down in text-books, but will come to the point. *Hygienic* treatment is desirable wherever such can be carried out. If we know that a certain occupation, a damp domicile, bad surroundings of the patient predispose if not actually cause rheumatism, what is more desirable than a complete change. Dietetic treatment should be encouraged wherever there is a so-called rheumatic or gouty diathesis present.

Internal treatment is practically useless. Salicylates, potassium iodid, arsenic, iron, colchicin and a host of other remedies have been tried but with what success everybody knows. A friend of mine asserted enthusiastically that he could cure every case of rheumatism, provided the patient takes unusually large doses of natrium salicylicum, but I never tried it more than once. The untoward effects this drug caused were more than my patient, a robust fellow, could stand.

External applications are quite popular, and rheumatic liniment manufacturers reap a [illegible] harves (financially, of course). Occasionally [illegible] ore much pain and tenderness I presc [illegible] solution of menthol, but expect a tem [illegible] o

Electricity, both the faradic and galvanic current, are of little avail. Several years ago I treated a good many patients with this method. I had them come to my office daily for months and then they went away dissatisfied, claiming that while they felt somewhat better from such a prolonged treatment they expected permanent cures. From the strong faradic current I saw no benefit at all

When I contracted this affection which, by the way, located itself in my elbow and wrist joints of both hands, as well as in the form of a pleurodynia (making me at first believe I had some heart trouble), I thought of going to our nearest watering place—Mount Clemens. For various reasons, and on account of some cases demanding my personal attention I could not do this, so I decided to try the dry-hot air treatment which was recently so highly praised in French literature. I purchased from Messrs. Frank S. Betz & Co. of Chicago, their arm and leg bath, took four baths and was relieved. It occurred to me then that I was mistaken in my diagnosis. I then called on six parties, all of whom are my patients afflicted with one or the other form of chronic rheumatism, with which affection they went around considering it of no avail to take further treatment. Relief followed immediately after the first bath in each of the six cases. Of course they would feel the symptoms return the next day. Then other baths were taken.



The following is a list of the baths administered:

Mr. A. F., aged 36. Had rheumatism two years. May 11, duration 18 minutes; May 12, duration 19 minutes; May 13, duration 21 minutes; May 14, duration 24 minutes; May 15, duration 26 minutes; May 16, duration 21 minutes; May 19, duration 30 minutes.

Mrs. A. F., aged 36. Had rheumatism five years. May 13, duration 18 minutes; May 14, duration 20 minutes; May 15, duration 22 minutes; May 16, duration 24 minutes; May 17, duration 26 minutes; May 19, duration 29 minutes; May 21, duration 22 minutes.

Mr. E. C., aged 29. Polyarthritis chronica, 2½ years. May 12, duration 15 minutes; May 13, duration 17 minutes; May 14, duration 22 minutes; May 16, duration 29 minutes; May 18, duration 30 minutes.

Mr. N. B., chronic muscular rheumatism, 3½ years. May 12, duration 10 minutes; May 13, duration 12 minutes; May 15, duration 15 minutes; May 16, duration 18 minutes; May 21, duration 22 minutes; May 22, duration 29 minutes; May 23, duration 30 minutes.

Miss E. T. My assistant, aged 24. Chronic rheumatism of muscles of arms, 1½ years. May 11, duration 18 minutes, temperature 205° F; May 12, duration 19 minutes, temperature 206° F; May 13, duration 20 minutes, temperature 211° F; May 14, duration 22 minutes, temperature 215° F; May 17, duration 30 minutes, temerature 220° F.

Mrs. F. D. Polyarthritis chronica 6 years, aged 38. May 10, duration 15 minutes, temperature 201° F; May 11, duration 20 minutes, temperature 202° F; May 12, duration 19 minutes, temperature 205° F; May 14, duration 21 minutes, temperature 209° F; May 19, duration 24 minutes, temperature 212° F; May 21, duration 26 minutes, temperature 217° F.

Dr. G. B. Writer, polyarthritis subacuta; pleurodynia a few weeks. May 2, duration 20 minutes, temperature 205° F; May 3, duration 22 minutes, temperature 208° F; May 4, duration 25 minutes, temperature 204° F; May 6, duration 30 minutes, temperature 221° F.

In every instance the apparatus was first heated about eight minutes, before treatment was begun.

In every one of the instances complete relief from all symptoms was experienced, and now within two months no recurrence, although we had here the most changeable and undesirable weather, and although all of the patients took neither any medicines whatever, nor did they change their mode of life, occupation and surroundings. One patient goes to his damp rag-shop daily; the other patients continued their usual lives. No massage was practiced after the baths save that I anointed the hands or legs with a little vaselin.

Of the value of dry-hot air in chronic rheumatism there can be no question. Shoemaker, Bartholow and other eminent authorities speak of it highly in their text-books on materia medica.

I have no doubt but what such treatment may prove of great utility in ankylosis, rheumatoid arthritis, similar affections and Bright's disease, but am unfortunate enough not to have had as yet any practical experience with such cases, but undoubtedly will use my bath again should any such cases come under my observation.

The hot air bath I use is a very neat looking piece of office furniture. It is an oxidized metal cylinder thirty inches long, fourteen inches high; a funnel and and pipe of same material carries hot air from a nickel plated heater to a hot air distributer. There is no smoke or smell. By means of several valves the heat can be regulated. A thermometer registers the amount of heat. The cylinder is lined with asbestos, arm or leg rested in a Turkish hammock. There are attachments for arms, legs, and other regions.

I am indebted to the manufacturers for the accompanying cuts which show the instrument plainer than any description could do.

115 Miami Avenue.

REST.

Presented to the Section on State Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, at Philadelphia, Pa., June 1-4, 1897.

BY C. F. ULRICH, A.M., M.D.

WHEELING, W. VA.

Rest is the restorer of lost power. Motion is the result of force exerted upon matter, and so long as the force continues to be applied and there are no impediments, the motion will continue. But to the motion of terrestrial bodies impediments always exist, and however much the motion may be stimulated by the renewed application of force, it will be retarded, and will ultimately cease. As an illustration, let us consider an engine run by water power, steam or electricity. As long as the power is applied, the engine runs, for a while, smoothly and with ease. Soon interruptions occur; there is a jar, and a hitch in the action. If this is not looked into and remedied, the machinery begins to run irregularly and something gives way. It either stops altogether, or its action becomes inefficient and the product of its labor useless. One of the most prolific sources of impediment in such machines is friction. This is obviated, as far as possible, by lubrication. But the oil may be carelessly applied or may be of inferior quality, charged with impurities of a gritty nature, thus failing to prevent friction. Parts of the machinery become oxidized, corroded by acids or ground by foreign bodies that find their way into it. Parts are loosened by the violence of the motion, and this condition communicates itself to other parts, until the whole machine is out of order. Now the engine has to be stopped for repairs; the parts worn out or broken replaced by new ones, others cleaned, smoothed and otherwise made fit for use again. Most engines work all day and rest at night, during which period the "master of repairs" examines it and remedies any defect he may discover, in order that it may be able to resume work in the morning. When the works have to run day and night, and no period of rest can be allowed, they usually have duplicate engines, one of which can rest for repairs while the other is in action.

The human body is a wonderfully complicated machine, yet exhibiting an admirable simplicity in its arrangement and working. It has a "master of repairs" whose name is "Vis Medicatrix Naturæ." This repairing power dwells within and exercises its function all the time. If the body is properly nourished, the materials for repair are always present. By the process of assimilation the nutritive material is appropriated by each organ or tissue in quantities sufficient to supply the loss, while at the same time a depuratory process is going on to rid the system of the waste material resulting from activity or disease. The latter is accomplished by the emunctories or outlets: the bowels, the kidneys, the skin, the lungs. This double process, assimilation and depuration, need not be discussed here. In childhood nutrition must exceed waste, in order that the child may grow. In age the waste usually exceeds nutrition, as the body is wearing out; although this is not always apparent, on account of the deposit of fat. In the middle period of life, there should be a fair balance between waste and repair, which will be the case in a healthy body, provided no excessive or too long continued labor is imposed on any part of the organization. The system requires a certain amount and a particular kind of nutritive material to keep the animal machine in motion. If this were always systematically administered, the proper balance would be maintained and the body would continue healthy, barring external influences. But, owing to circumstances producing variation in the activity of some of the functions, thus increasing or diminishing the waste, the quantity of the required nutrition varies very materially. Besides, the ignorance of the individual as to what constitutes suitable nutriment, the unrestrained indulgence of the appetite, on special convivial occasions perhaps too frequently repeated, cause many to take too much food, or of an improper kind, along with undue quantities of intoxicating beverages. The food on these festal occasions is frequently of a richer and less digestible character than can be easily disposed of by the gastro-intestinal tract. Hence ensue various ailments, by which the whole machinery is disabled; such as gastritis, enteritis, gastro-intestinal catarrh, followed by dyspepsia and its accompanying horrors. The average man or woman now begins to take medicine: pepsin, peptonoids, stomach tonics, aperients, purgatives, etc. This may relieve temporarily in some instances, but generally leaves the digestive apparatus in a worse condition than before. These helps to digestion cause the stomach to depend upon them, instead of doing the work itself. As regards the purgatives which are so universally taken, and so frequently recommended by physicians, it is not known to the laity, and not always thought of by the medical practitioner, that they are detrimental to digestion, since they induce excessive peristalsis in the upper intestines, thereby driving off much of the partially digested nutritive material, together with the intestinal fluids that are essential for completing the process of digestion and preparing the product for assimilation. My favorite remedy, and doubtless the one to be preferred, is rest. When the headache and the acid eructations give evidence of the failure of the stomach to do its work, and of the consequent fermentation of the ingesta, I advise my patients to drink a quantity of warm water and give the stomach a rest. This will give the "master of repairs" dwelling in the body, time to correct the congestion which prevents the development of the gastric fluid and the resulting digestion of the food. After the expiration of the period of rest, I put them upon a suitable diet, both as respects quantity and quality, at the same time prescribing some simple innocuous medicine that will in some degree assist nature without interfering with any function. The homeopaths give medicine in infinitesimally small doses, endlessly diluted, and impress it on their patients that the slightest violation of their rules of diet and hygiene will render the remedy inert or even injurious. The rest which the stomach enjoys during its fast, the subsequent moderation in eating, with judicious selection of food, is what accomplishes the cure, unless actual destruction or perversion of tissue had taken place before the case came under the observation of the physician.

Let us now consider the muscular system. We know that every movement made by a muscle results in the destruction of a certain amount of its tissue. If the muscles are too severely taxed by unusual exertions, or by too long continued exercise, the waste is greater than the repair. A portion of the waste, not being entirely removed by the emunctories, remains as an irritant. The result is an unhealthy contraction of the muscles, in the form of cramps or twitchings, and the final wasting away, with the loss of power. Here again the best remedy is rest. By rest I do not mean the absolute cessation from labor, but moderate exercise, or such a change of movement as will bring another set of muscles into play, giving those that have been overworked less to do, which is often better than absolute quietude. The repairing force that exists and exercises its function in every department of the human organization, immediately goes to work to replace the wasted tissue and restore the lost power. While the organs are in full activity, the waste exceeds the repair and there arises an absolute necessity for rest. For this purpose nature has provided sleep, during which all the voluntary forces are held in abeyance, giving the nutritive apparatus a better opporunity for its work of restoring the lost power. The involuntary or automatic part of the system goes on all the time, but much slower during sleep, which is also equivalent to rest; for during the night's repose so much of the external disturbance is removed that the vital processes, viz., the circulation of the blood, the result of the heart's action, the act of respiration, the silent process of digestion and assimila[illegible]av-ing less to do, can afford to work more at their ease than during the active employments of the day. The *vis medicatrix naturæ* not only supplies new material to replace the worn out and damaged portions of the organic tissue, but also provides "garbage carts" to remove that which has become useless and would clog up the works, thereby causing disease and often deranging the entire machine. I refer to the emunctories mentioned before. We will discuss one of these, the kidneys.

These constitute one of the most important organs of the body, since they separate from the blood the worn out material and the product of diseased or unhealthy action. This double organ is frequently overworked by the consumption of beer and other alcoholic beverages. It then loses its power of selecting and removing the superfluous and deleterious substances which must be carried off in order to preserve the health. In consequence of this the kidneys become diseased, so that their work is either not done at all, or their action is perverted, removing what is necessary to health and life, while allowing noxious substances to remain for the destruction of vitality. Now, if the kidneys were permitted to rest, *i. e.*, their labor modified and reduced, as I have explained, this diseased condition might be avoided. Abstemiousness from vinous and malt liquors, and the substitution therefor of innocuous beverages necessary to maintain the liquid condition of the blood and the proper consistency of the tissues, would so regulate the work of the kidneys that they would remain healthy and retain their normal powers. If more rest than this is required, the skin may be called in to do vicarious work, which can be done by diaphoretic treatment, hot vapor bath, etc. Overwork of the kidneys may also be prevented by a proper regulation of the bowels; for there is no greater enemy to the kidneys than habitual constipation, since that condition imposes upon them the labor of removing unappropriated material which can only with safety be done by the bowels.

Let us now speak of the most important organ of the body, the *primum mobile*, the great dynamo that moves and gives life to the beautiful and complicated human machine—the cerebrum. This is subject to the same physical laws as the rest of the organism. Every effort of the brain to induce motion of the muscles, through its electric wires, the nerves: every thought; every emotion, every strain on the mind, wears out a certain portion of it. If the brain is engaged in continuous action by day, and does not take the necessary rest at night, an unhealthy condition will ensue, resulting in lassitude, inability to perform its functions, perversion of its powers, and finally insanity or imbecility. Before the final catastrophe is reached, all sorts of irregularities in the general health occur, on account of the great influence of the brain on all the functions of the body. Now, if the brain enjoys its regular periods of rest, by relaxation from labor during certain hours of the day and undisturbed sleep at night: an extended rest during parts of the year, by change of occupation from the ordinary routine of business to something engaged in for pleasure, it will remain strong and healthy: more and better work will be done in the limited period than could be accomplished in a much longer time without the much needed rest. Excessive labor imposed on the brain by day prevents it from the needful repose at night, for there will be either no sleep at all, or at least unpleasant dreams; the brain working without the restraints that hold it in check during the waking hours. Then, when morning dawns, the poor brain is not rested at all, but is as tired as if it had worked hard all night. The waste thus caused is so great that it will be very difficult to make it up. When the brain is well treated, by systematic labor and a reasonable rest at proper times, it will last much longer than when it is abused by excessive, irregular and spasmodic work. We have examples of men who reached eighty, ninety, and even a greater number of years, whose minds remained clear and bright to the last. I shall mention Humboldt, Moltke, Bismarck and Gladstone, the last two of whom are living yet. But why should I cross the ocean, or go out of our own profession to find examples? Behold the great autocrat of the breakfast-table, the poet physician, Oliver Wendell Holmes! and in our midst, our noble and venerable founder, Dr. N. S. Davis, who has completed his eightieth year, who was the first to suggest the organization of the now famous American Medical Association, the fiftieth anniversary of which we are celebrating. For fifty years he has upheld and labored for the Association. Today his mind is as clear and his zeal as untiring as it was half a century ago. Had he committed excesses of any kind during that long period, we would not now rejoice at his encouraging presence and co-operation on this auspicious occasion. May he live many years yet to hold up the hands of the noble band of men whose pleasing duty it is to guard the health and the lives of our American citizens, and to rejoice in the success and prosperity of the American Medical Association!

All teaching is best enforced by example. If we desire to be heard and obeyed by our clients we must set them a good example in our own conduct. Let us be moderate, taking a reasonable rest in eating, in drinking, in physical exercise, but especially in the labor of the brain, which is the organ most extensively used, and often most abused, by the highly educated and constantly employed physicians. Let us exercise our powers systematically and cautiously, looking to the advantage and benefit of our patients, but at the same time not forgetting ourselves. The physician should take a short rest every day. If he is engaged during the night, let him enjoy a siesta in the daytime. A little recreation at moderate intervals during the year would be of great benefit. Rural excursions, away from the noise, dust and turmoil of the city, would recuperate his tired body and exhausted mind so that he could return to his work fresh, rejuvenated and full of vigor. But of all things, let him not fail to take a lengthy vacation once a year. If in winter; he can rest himself in the orange groves of Florida; or, should his means allow it, he might repose in the classic shades of beautiful Italy. In the summer the magnificent lakes of the north, or the delightful resorts on the seacoast will afford the coveted rest and recuperation. But under no circumstances should he fail to attend the meetings of the American Medical Association, where he will meet his colleagues from the North, South, East and West, enjoy an interchange of views and cultivate the social side of his otherwise hard life, of which he sees but little while toiling to improve health and save life. Pursuing this course, the physician will be happier, healthier, stronger, both in body and mind, will live much longer, and will enjoy his intellectual faculties to a ripe old age. Then, when his allotted time is completed, he will enter upon his everlasting rest, respected, loved and honored by his contemporaries, while his memory will be cherished by a grateful posterity.

TWO CASES OF TRISMUS NASCENTIUM SUCCESSFULLY TREATED BY TETANUS ANTITOXIN.

BY JACOB FRIEDMAN, M.D.
PROFESSOR OF DISEASES OF CHILDREN AND CLINICAL MEDICINE, BEAUMONT MEDICAL COLLEGE.
ST. LOUIS, MO.

Within the past five weeks I have had an opportunity of experimenting with tetanus antitoxin in the treatment of two cases of trismus nascentium. This disease of infancy has been almost uniformly fatal and, notwithstanding the fact that all kinds of treatment have been used, has thus far resisted every measure.

On learning of the successful treatment of tetanus in the adult by the serum treatment, I determined to try the same remedy for the infantile disease. By reason of the extreme youth of the patient one has no guide as to the quantity of the serum to be used. As will be seen in the first case, knowing that the child would die under the ordinary plan of treatment, a large dose was used in the beginning, considering the weight of the child as compared with that of the adult, in which a full bottle is usually administered.

In both instances the serum used was of Gibier's make, the product of the New York Biological Institute. The manufacturers give directions to the effect that the entire contents of one bottle should be used every six hours until improvement sets in. In both cases two bottles were used, and all the serum was absorbed within six hours. There were no rise of temperature, no abscess and no eruption of any character. Immediate improvement resulted after each injection, and this was made more noticeable by the fact that the children were at the worst in the morning. The convulsions therefore appeared in the morning, since the children had received no injection during the night. During the day both children rested well. Their convulsive movements, or convulsions, were the first symptoms that yielded. In addition to the serum, both children were given from ½ to 1 grain of chloral every three hours.

Case 1.—Girl ten days old, parents poor, and consequently their surroundings were not of the cleanest. Umbilicus slightly suppurating, jaws thoroughly locked, inability to nurse, fever, convulsions, etc. On seeing case, one-third of a bottle of serum was immediately used, and this was repeated in six hours. As the last injection was given at 6:30 P.M., the child had no serum until 9 o'clock the next morning, when a further injection was given, and as the improvement seemed marked, only one-sixth of a bottle was given at the next injection. As before stated, two bottles were used. Patient has entirely recovered.

Case 2.—Boy fourteen days old, conditions and symptoms similar to first case. I proceeded exactly as in the first case and obtained the same results. Both patients are nursing again, and were able to begin nursing after three days' treatment.

I have during my practice seen a large number of these cases, which have come both from dispensary practice and a large charity practice among the poor Russian emigrants which I did in my early professional life. Heretofore, I have seen only one case recover. The successful issue of the two cases reported is very gratifying, and certainly will lead me to adopt the same method in the treatment of similar cases.

2834 Clark Avenue.

THE OPHTHALMOSCOPE AS AN AID IN GENERAL MEDICAL DIAGNOSIS.

Read before the Indiana State Medical Society, May, 1897.

BY L. D. BROSE, M.D., PH.D.
OCULIST AND AURIST ST. MARY'S HOSPITAL, EVANSVILLE, IND.

Every man, in the general practice of medicine, is continually meeting with patients whose symptoms are obscure and the question of diagnosis is long unsolved. A careful ophthalmoscopic examination in these cases may at once detect hidden eye lesions that not only serve to identify the general disorder but also furnish us a correct prognosis. Perhaps the relation of a few cases at the outset will make the subject more interesting and impress you with the importance of giving this matter your close attention.

Joseph G., aged 27 years was referred to me by Dr. Edwin Walker. He complains of seeing very poorly, and of headache in the back and sides of the head. The left leg is often numb and there is a pricking sensation to the feet as if his shoes contained pins. The patella reflex is present and the urine negative. The pupils react to light, while the general external eye appearances are normal. With the ophthalmoscope both optic discs are clearly defined but of pale color, indicative of primary atrophy. The blood vessels are normal in size and without discoverable pathologic lesion. Field of vision is contracted peripherally and there is a central scotoma in either eye. He counts fingers at five feet. Diagnosis: Multiple sclerosis.

H. G., a German 38 years old and married, comes with a history of double vision during the past twelve months. He admits having had syphilis nineteen years ago. Patella reflex present. Both pupils strongly contracted and without reaction to light. The left external rectus muscle is paralyzed and both optic nerves are atrophied. With the right eye he sees 15 cc and with the left eye 15 xx. The field of vision shows peripheral contraction with islets of color scotoma for green and red. Diagnosis: Locomotor ataxia.

Mr. L. H., unmarried, 21 years old, was sent to me by Dr. H. T. Dixon, May 23, 1891, because of poor eyesight. He had been at work up to within a few days and was not aware he had any serious trouble other than that of sight. Vision in the right eye was reduced to recognizing hand movements, and in the left eye to counting fingers at eight feet. Ophthalmoscopic examination detected retinitis in both eyes with radiating whitish patches around the macular regions and numerous retinal hemorrhages. Both optic discs were swollen and their outlines obliterated. The urine was highly albuminous with many granular tube casts. Diagnosis: Bright's disease of the kidney. Patient was unable to come to my office again but was attended by his regular physician, death ensuing within three weeks from the time he first consulted me.

F. K., a farmer, was sent to me Aug. 24, 1895, with the history that several months before his eyesight became so bad that he could scarcely read. The vision then slowly improved again but now had relapsed so that patient was advised to consult an oculist. With the right eye he counted fingers at ten feet and with the left eye he saw 15-c. The ophthalmoscope showed both optic nerves swollen, very indistinctly outlined, many small retinal hemorrhages and whitish star-shaped patches around the central zones of vision. The urine was highly albuminous and with a specific gravity of 1010. His physician was advised that the patient had albuminuric retinitis and that in all probability he would die within twelve months. He did not accept our prognosis, but informed the man, who looked in the best of health, that he would treat his case himself and that he might expect to recover his sight. In less than six months the patient died.

C. B., 44 years old, came to see me the first time in 1893, saying he had trouble with his eyes. His general health was not good although he continued attending to his law practice. He has steadily lost flesh during the past two years, notwithstanding his appetite was good. Vision in the right eye 15 xv, in the left eye 15 xl. He was slightly hyperopic and with the correcting lens for this and his presbyopia read Snellen 1 1-11 both eyes. The ophthalmoscopic examination disclosed in both retina, retinitis with whitish patches in the region between the disc and macula. No hemorrhages were discovered, and the outlines of the optic nerves were clearly defined. The urine showed a trace of sugar. Diagnosis: Retinitis diabetica. In 1894 he made a visit to Hot Springs and returned with his vision greatly improved, the whitish patches however had not disappeared. Patient died a year later.

H. H. B., 40 years old, consulted me Jan. 12, 1892, because of disturbed vision in the left eye. With the right eye he saw 15-xxx and with +2.5 correcting his hyperopia he saw 15-xv. Sight in the left eye was reduced to counting fingers at twelve feet. The ophthalmoscope revealed retinal hemorrhages in both eyes with disease of the retinal blood vessels. Patient denied ever having had syphilis, nor has he ever been addicted to the use of alcohol. The urine was free from sugar and albumin. Diagnosis: Retinitis hemorrhagica, due to disease of the retinal blood vessels. Patient was cautioned to give up much of his business and take a prolonged vacation in the early future. Internally, iodid of potash was prescribed. The advice however was not heeded and the vision in the left eye rose with +2,5 lens to 15-lxx. Within a year he had a slight cerebral hemorrhage, followed in another twelve months by a second that terminated his existence.

In our ophthalmoscopic examinations of the optic nerve we recognize two kinds of atrophy. Such as have been occasioned without inflammatory neuritis and hence termed primary or genuine atrophy; and such as have been preceded by swelling of the nerve fibers and other evidences of inflammation and termed consecutive atrophy. The causes of primary atrophy of the optic nerve are to be sought for in disease of the brain or spinal cord, or in disease located in the course of the optic nerve itself, which through injury or pressure has its conducting function interfered with. In general paralysis of the insane, primary atrophy of the optic nerve may occur at a very early period and its significance is then of great diagnostic and prognostic importance. The general nerve appearances are very like those seen in locomotor ataxia. One difference though may at times be found in a slight preliminary cloudiness of the papilla and adjacent retina.[1] Gowers says he has observed this a few times but that much oftener it has been wanting. Reflex rigidity of the pupil may long continue as a prodromal symptom of the disorder. Other eye muscles may very early and in seeming perfect health be paralyzed singly or in groups, which paralysis is often temporary but subject to relapses. The visional field, unlike that in tabes, is apt to show concentric narrowing, with central interference in color conduction. Eye symptoms in multiple sclerosis are often quite characteristic and of the greatest value in establishing a diagnosis. Nystagmus and tremor when fixing an object must be looked for and are occasioned through insufficient innervation of the nuclei of the ocular muscles. Disturbance is found in the peripheral visional field in an irregular narrowing and may be concentric, with central color scotoma that seldom becomes absolute.[2] The impairment of sight may appear at the beginning of the disease and may even remain the sole manifestation of the disorder for a long time. The characteristic is frequent improvement and relapse in keeping with improvement or a growing worse of the patient's general condition. The scotoma may be one-sided, again peripheral, then disappear and reoccur central. The optic disc is changed to a grayish white color, and later becomes excavated so that the lamina cribosa is seen. The disc outlines however remain clearly defined while the blood vessels of the fundus are in general little altered in caliber or course.

The frequency of optic nerve atrophy in locomotor ataxia is variously estimated. Gowers mentions 13 per cent.; Galezowski says about two-thirds of all primary optic nerve atrophies are due to tabes, while Charcot places it still higher and says that in nearly every case, even if spinal symptoms are at first absent, they will appear at a future period. Prof. Uhlhoff, now of Breslau, who perhaps has done more original investigating in this line than any other oculist. says not more than one-half of the cases of primary atrophy are associated with disease of the spinal cord. Ophthalmoscopically we see a gray discoloration of the optic papilla beginning, as a rule, in the outer half; it extends slowly over the entire nerve, which later becomes excavated, so that the meshes of the lamina cribrosa may be seen. The field of vision shows peripheral contraction perhaps in islets or sectors but we especially look for contraction in the outer and upper part of the field. Central positive scotoma hardly ever occur and should make us doubtful of our diagnosis. Disturbance in the color field is important and has a bearing on the prognosis. Where the color narrowing is relatively very much greater than for white, the the disease may be expected to progress rapidly. Conversely, contraction of the color boundaries in keeping with the rest of the field denotes a slowly progressive or stationary disease. There is great disproportion between the visible atrophy of the optic disc and the disturbance of vision.[2] As a rule, however, when the discoloration of the disc is much greater than we might expect from the amount of disturbance of vision, the case is apt to be slowly progressing. The ophthalmoscope may reveal total gray discoloration of the disc although there is hardly any disturbance of vision. Muscular disorders of all kinds occur with great frequency in tabes, and are nuclear or peripheral in nature. In fact every paralysis of an eye muscle, occurring suddenly in a person in health and without an injury, should arouse a suspicion of a beginning tabes, the more so if it recovers in a comparatively short time or subsequently relapses. According to Kahler of Vienna, abducens palsy is the most frequent, ptosis next. Pupillary symptoms are very frequent and of great diagnostic value. Absence of light reaction, followed by loss of reaction to accommodation and convergence, is one of the most characteristic signs of beginning posterior spinal sclerosis. Consecutive atrophy of the optic nerve is the final stage of a papillitis or retinitis and is due to the newly formed connective tissue in and between the nerve fibers, interfering with their nutrition. During the active stage of the disease the nerve head is swollen, its margins obliterated or very indistinct, and the color reddish, approaching that of the fundus. Through mechanical congestion the veins become distended and tortuous, while the arteries are either unchanged or smaller. As the inflammatory symptoms decline the outlines of the disc are again seen, and may grow irregular or even smaller than in health. The color changes to white but the lamina cribrosa remains invisible. The blood vessels now grow smaller and many are enclosed by whitish lines. Intracranial disease, such as tumors, menigitis, brain abscess and cerebral softening from vascular obstruction, is by far the most common cause of consecutive atrophy of the optic nerve. Systemic disease associated with the retention of morbific or toxic material in the blood may likewise occasion optic neuritis. Local lesion in the orbit may cause a unilateral form. Retinitis is in most cases a symptom, the proper interpretation of which will lead to the detection of its cause in some constitutional disorder. To such causative disorders we first place albuminuria, then diabetes, syphilis, blood diseases like leucocythemia and disease of the blood vessels. Retinitis albuminurica is characterized, in addition to the common symptoms of retinal inflammation, such as diffuse retinal cloudiness, veiling of the disc outlines and blood vessels with frequent congestion and tortuosity of the same, by white spots or patches of fatty degeneration of the retinal elements and cellular exudate. These white spots are found characteristic in two places, in circles around the optic nerve, or radiating star-like around the macula. Especially typical is the latter stellar-like arrangement of the white spots. Hemorrhages may be found in all parts of the retina, coming chiefly from the retinal veins and capillaries, as shown by the striated appearance of the extravasated blood. Every form of nephritis may give rise to retinal trouble; however it is found oftenest with the cirrhotic or interstitial kidney disease. The relation between the eye lesion and the kidney disease is that the retention of waste matter in the blood sets up a disease of the blood vessels of the eye and as a sequence inflammation and degeneration of the retina. The intensity of the eye lesion bears no fixed relation to the severity of the nephritis nor to the amount of albumin in the urine. On the contrary the eye lesion may improve while the kidney disease is growing worse or the kidney disease improve and the eye lesion grow worse. Nevertheless, retinitis renders the prognosis very grave in albuminuria, and it is a fact that most patients die within one year after the eye lesion has been recognized by the ophthalmoscope. Uremic transitory blindness is a different trouble than the one we have just considered and is accompanied by vomiting, convulsions and the general symptoms usually present in uremic poisoning. Retinitis diabetica is, following Hirschberg,[3] best depicted under two principal types. Where we find whitish spots in the retina lying between the upper and lower temporal branches of the central artery and to the temporal and nasal side of the optic nerve. As the patches enlarge they become striated or crescent shaped. The star like patches as seen in albuminuric retinitis are never present without the urine contains albumin as well as sugar. Likewise in and around the white spots do we note the absence of pigment degeneration which is so common in syphilitic retinal trouble. Small hemorrhagic points, lines or spots may be found in all parts of the retina and even a hemorrhagic spot may rest upon one of the whitish exudates. The fact that the hemorrhages do not overstep a certain degree of severity is characteristic. The hemorrhages may undergo reabsorption, but Hirschberg says he has never seen the whitish patches wholly disappear, notwithstanding improvement in vision and the general symptoms. The absence of diffuse retinal cloudiness and the non-involvement of the optic disc with veiling of its outlines, are of great value in differentiating this trouble from albuminuric retinitis.[3] The second type of the disease is the purely hemorrhagic, spontaneous hemorrhages occur and are due to sclerosis of the blood vessels, not only in the retina but in the brain and other parts of the body, Subconjunctival hemorrhage in an apparently healthy person may have a connection with diabetes; likewise a chronic and persistent inflammation of the eyelids. Hemorrhage into the vitreous may happen with or without hemorrhagic glaucoma diabetic in origin. Cataract is a frequent accompaniment of diabetes in both the young and the old. In addition, diabetics have trouble in accommodation and require frequent changing of their reading lenses and a strength out of all proportion to their presbyopia. A very rapidly developing myopia without lens opacity is sometimes found in persons long past middle life. While our purely hemorrhagic type is less characteristic of diabetes than is our exudative, its prognostic value, so far as the preservation of sight and even life is concerned, is more grave. Hemorrhagic retinitis independent of diabetes and albuminuria or alteration of the qualtity of the blood, but associated with vascular derangement such as general arterial sclerosis or endarteritis need interest us here only for the unfavorable prognostic value it has upon the patient's life expectancy.

REMARKS ON OTITIS MEDIA AND OTITIC SYPHILIS, WITH REPORT OF A RHINOLITH AND AN ACCESSORY TOOTH IN THE NOSE.

Read before the South Carolina Medical Association at Union, S. C., April 26, 1897.

BY EDWARD F. PARKER, M.D.

PROFESSOR OF PHYSIOLOGY AND ASSISTANT IN DISEASES OF THE EYE, EAR, NOSE AND THROAT, MEDICAL COLLEGE OF SOUTH CAROLINA.

CHARLESTON, S. C.

The etiology, symptoms and pathologic changes of an ordinary case of acute suppurative inflammation of the middle ear are more or less familiar to us all. The formation of pus in the tympanic cavity is usually followed by rupture of the drumhead and the discharge heralds an approaching sure and speedy recovery if drainage is free enough to permit the early exit of the pus. Such a case, free from complications, pursues a regular course and tends under careful hygienic and rational treatment, to spontaneous cure. Often, however, we meet with cases when for some reason the tympanic membrane does not yield to the pressure and the pus after invading the mastoid antrum and cells, may have to seek another outlet. The Eustachian tube, the natural ventilator of the middle ear, rarely serves as a drainage tube on account of the closure of its small lumen from inflammatory swelling, originating usually in the naso-pharynx. In such cases the bony tissues are necrosed and the pus seeks an outlet in the cranial cavity or some of the venous sinuses or arteries passing in close proximity to the attic. Again, after rupture of the drumhead the opening may not be large enough to permit free drainage and the tympanic mucous membrane being constantly bathed in a septic purulent fluid becomes subject to polypoid degeneration; and for this or other reasons the discharge becomes chronic. It is to two of these complications that I invite your attention with illustrative cases.

W. E. N., aged 24, of Dock, S. C., consulted me by advice of Dr. Steele, on March 11, 1897, for deafness in and a chronic discharge from the right ear. Two months previously he suffered from an attack of grippe with violent pains in both ears. The right began to discharge ten days after and had not stopped since. In the interval he had recurrent attacks of severe mastoiditis. On examination the skin over the mastoid was found swollen, boggy and painful on pressure. Hearing was reduced to two thirty-sixths in the right ear and the external canal was closed by a soft fluctuating tumor with a fistulous tract opening on its surface. The drumhead, not at first observable, was subsequently found intact. The fistula communicated with the mastoid cells and the bony canal was considerably necrosed. *A free incision was made through the tissues of* the external auditory canal and the [illegible] t and [illegible]acent diseased bone thoroughly curetted [illegible] iodoform gauze. Free drainage was thus [illegible] weeks after, the patient reported hi[illegible] ormal in every respect.

---

[3] Deutsche medicinische Wochenschrift, No. 51, 1890.

This case illustrates the necessity of an early paracentesis of the drumhead in cases of acute purulent otitis media when the usual local antiphlogistic measures fail to give rapid relief from the pain, or to cause a disappearance of the other symptoms. In such cases as the above, the early establishment of free drainage by myringotomy will prevent mastoid and other complications of a serious and often fatal and intractable nature.

As illustrative of another common complication of suppurative otitis media we have those cases in which the drum membrane is perforated and a train of symptoms is set up, the most prominent and annoying of which is an offensive and irritating discharge caused by the opening being too small to permit the exit of the purulent secretion collecting in the middle ear.

F. A. B., aged 25, of Sumter, S. C., consulted me by advice of Dr. Archie China, in November, 1896, in regard to a chronic fetid discharge from the right ear, which had existed for about twenty years, in fact as long as he could remember. During this time he had been subjected to a great variety of treatments at different hands, among them being the galvano cautery. His hearing was reduced 0.36 and bone conduction was considerably impaired. On examination, a small opening was found in the postero-inferior segment of the drumhead and closing it, was what seemed to be a polypus or granulation. The membrane looked very tense and the discharge was free and offensive. Suspecting a polypus of too large dimensions to protrude through the perforation, the latter was enlarged and a tumor of unusual size presented. This was extracted with an aural snare, under a 20 per cent. solution of cocain. The patient returned home and was directed to use only a peroxid of hydrogen solution, to inflate the ear with Politzer's air bag, and after thoroughly drying the canal to insufflate dry boric acid. In three days he reported the discharge cured and there has been no return since; the same treatment, however, was continued for some time.

In all cases of chronic discharge from the ear, when thorough cleanliness and appropriate local and general treatment fail to stop it, a very careful examination should be made for some exciting cause. Such causes are polypi, necrosis of the ossicles or bony walls of the attic, cholesteatomatous masses, foreign bodies or diseased conditions of the nasopharynx producing sepsis through Eustachian tube. In children, the most common cause is adenoid growths and their removal generally suffices to cure the disease.

The following history describes a variety of otitic syphilis which is no doubt very commonly overlooked and of which very little has been written:

M. C., aged about 22, consulted me on Jan. 27, 1897, at the request of Dr. Dawson. With no previous history of ear disease he had suddenly become perfectly deaf in both ears. The left one subsequently discharging a fetid purulent secretion. A short time before I saw him he began to have ringing noises in the head and at the same time had marked attacks of vertigo, while his gait was so staggering that he was unable to walk out of the house unassisted. Complete facial and partial paralysis of other portions of the body occurred simultaneously. Both drum membranes were congested and the left perforated by a small opening. Double vision was occasionally present. Both air and bone conduction were almost completely abolished. He gave an obscure history of syphilis, which was subsequently confirmed by other clinical evidences of the disease, as well as by the report of his physician. Under heroic antisyphilitic treatment, including subcutaneous injections of mercury in large doses and iodid of potash internally, as well as local treatment of the ears. he is now able to hear loud conversation in the left ear at one foot, and the loudest in the right, with difficulty.

Dr. E. A. Crockett, in the Boston *Medical and Surgical Journal* of Feb. 11, 1897, under the title, "An Acute Syphilitic Affection of the Ear," details the history of several similar cases in which he found the injection of pilocarpin in the acute stage, in conjunction with antisyphilitic treatment, of great and even specific value. He concludes from a study of some fifteen or twenty cases that effusion into the labyrinth is the cause of this particular group of symptoms we are considering, and that very sudden and severe deafness, marked vertigo and violent tinnitus in persons free from ear trouble should always suggest otitic syphilis.

Your attention is also invited to two somewhat rare and unique growths occasionally found in the nasal fossæ, only a limited number of which have so far been reported in rhinologic literature. The first is an accessory tooth which I extracted from the left nasal passage of an adult, aged 29, who consulted me for a chronic discharge from the nose. The tooth, evidently a canine, was firmly imbedded about midway between the anterior and posterior openings, in the mucous membrane covering the bony floor formed by the hard palate. Its presence was a great surprise to the patient and its removal was followed by a rapid amelioration of the symptom complained of.

The second is a rhinolith or nasal stone removed from the left nostril of Mrs. H. C. R., aged about 45, who consulted me for deafness. She mentioned incidentally that she had suffered for upward of twenty years from a fetid discharge from the left side of the nose and from a chronic stricture of the lacrymal duct, both of which she considered incurable. In the course of a routine inspection of the nose as a part of the aural examination I detected a large rough irregular stone firmly lodged in an old suppurating ulcer just at the lower end of the tear duct. These rhinoliths are usually formed by the deposition of calcium phosphate around some forgotten foreign body as a nucleus. From the history of this case, as well as the shape of the stone, I judge that the exciting cause was a piece of necrosed bone from a diseased tooth extracted years ago. The annoying discharge ceased shortly after the removal of the foreign substance. As a predisposing cause of the chronic otitis its effect is somewhat doubtful but there is no doubt that it was the original source of the dacryo-cystitis and lacrymal obstruction.

THE TRAUMATIC FEVERS.

Read in the Section on Surgery and Anatomy, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY EDMUND W. HOLMES, M.D.
DEMONSTRATOR OF ANATOMY, UNIVERSITY OF PENNSYLVANIA; SURGEON TO THE METHODIST EPISCOPAL HOSPITAL.
PHILADELPHIA, PA.

One of the earlier theories of disease was that it came from without, as a direct visitation from God; later, that it originated in the humors of the blood; in modern times the cell doctrine has had its sway, to be supplanted as the microscope increased in power by the bacterial origin of disease, rapidly supplemented by the hypothesis that the products of the bacteria, the ptomains and leucomains, are in many cases the active media, while the more recent investigations of serum therapy seem to foreshadow a partial return to the humoralistic theories. It was only in 1851 that Meigs declared that puerperal fever was a fatality of God's providence; so that whatever the actual truth of our modern speculations may be, there is no pathologic process upon which they have had a greater effect in modifying our methods of treatment, in teaching us how to avoid their transmission, and in one of them (pyemia) in practically stamping it out, at least in its most virulent epidemic form, than in the class of diseases which we have the honor of discussing before you.

It is not so many years ago since we were taught by the too enthusiastic imitators of Lister, that any rise of temperature following an operation indicated infection. The most careful preventive measures with assiduous microscopic investigation has tended to dissipate this view; at the present time a moderate rise of temperature is not regarded as a reflection upon the surgical cleanliness of the operator, and it has been found by experiments upon the lower animals, that under the most careful asepsis, "*a something*" from a sterile wound, injected into a healthy animal, will bring about a rise of temperature, which "something" for the want of more definite knowledge, is called an "aseptic fibrin ferment" and therefore is supposed to be the element which being absorbed from an uninfected wound in the human animal, produces the increased heat. We would classify our traumatic fevers as *primary fevers* and *secondary fevers*.

PRIMARY FEVER.

Primary or aseptic fibrin ferment fever appears usually within forty-eight hours after a traumatism of any magnitude, being due to the absorption of an aseptic fibrin ferment substance from the seat of injury. It follows conditions in which the aseptic precautions or unbroken skin preclude infection, such as contusion, fracture, effusions into synovial sacs or membranes and in carefully cleansed open wounds, and is due to the absorption of pyretogenetic substances formed from the products of the aseptic necrobiosis.

It lasts from four to five days; with moderate rise of temperature (102), increase in the rate of pulse and of the respiratory rhythm, the urine more highly colored than normal, some tendency to constipation, but with little or no sense of discomfort to the patient. It is to be treated by absolute rest, limited diet, a purgative on the second day, an alkaline febrifuge, or moderate dose of quinin. It is not a condition that need give the operator any anxiety.

SECONDARY FEVER.

Secondary fever which comes on after the fifth day, though in virulent cases it may appear even sooner, is due to the absorption of pathogenic germs, either the pyogenic, the saprophytic, or their products, so that we may classify their varieties as follows. 1. Suppurative fever, acute or chronic. 2. True septicemia. 3. Sapremia. 4. Pyemia.

Acute suppurative fever.—Acute suppurative fever follows infection with the products of pyogenic micro-organisms and is manifested by a chill, fever and sweat usually coincident with the formation of pus. Although the appearance of such symptoms is a most valuable indication of the presence of a purulent collection which will usually promptly disappear when the pus is thoroughly evacuated and the cavity kept well drained, they may not occur though the pus may have accumulated in considerable quantities and for a considerable length of time, *until the cavity is opened.* It was formerly thought this was due to the admission of air. This is not so. The apparent paradox depends upon the conditions favorable or unfavorable to the absorption of the pus products.

In a paper entitled "Intermittence in Disease," I endeavored, some years ago, to show that the regular rhythmic appearance of phenomena in health or disease were due to impressions upon the nerve centers, pus absorption at times having the intermittent type of an ague, and being often mistaken therefor. When the pus collects rapidly and is not too large in quantity, the absorbent lymph or venous channels being active, the symptoms will appear quickly. Where however, the pus collects slowly and there is marked infiltration and pressure upon the surrounding tissue, thus interfering with the absorption, no symptoms will be evident excepting perhaps the initial chill, fever and sweat, which is often forgotten, but as soon as the cavity is evacuated and pressure relieved the absorbants regain activity, take up the infiltrated products which can not be readily drained out and we at once have the familiar symptomatology. The apparent paradox is thus made clear and there is no inconsistency.

Acute suppurative fever is believed to be due to the products of the pus and not to the actual presence of the pus-organism themselves, because the actual presence of the pus germs has not been demonstrated in the blood, and because the symptoms disappear so quickly after thorough cleansing and drainage.

The chronic form of suppurative fever with characteristic rhythmic temperature chart, "up at night and down in the morning," with flush of cheek and wasting of flesh, is called *hectic*.

Septicemia.—Septicemia (true septicemia, septic infection) is due to the absorption of the saprophytic or micro-organisms of putrefaction with their actual presence in the blood in enormous quantities.

The symptoms are, an initial chill (one only), a continued fever, rapid pulse and respirations, coma, sordes on the lips, a dry cracked tongue, mental hebetude, muttering delirium, with enlargement of the spleen and of the superficial lymph glands. The wound, if upon the surface, will often appear gangrenous and emit a foul odor.

The treatment consists in rigid local asepsis (although the disease when fully developed has already gone far beyond the point of infection), with most vigorous supporting measures, with liquid concentrated food, quinin, whisky, ammonia, digitalis, and strychnin, the amount of stimulus in the way of brandy or champagne without intoxication being somewhat surprising. Fortunately, true septicemia is much more rare than we might suppose. as the term is misapplied to a variety of conditions often including our next sub-division.

Sapremia.—Sapremia (toxemia, septic intoxication, ptomain poisoning) is the absorption of *the products* of the micro-organisms (ptomains) from the site of infection. It predicates, therefore, a primary local invasion with saprophytic germs and an absorption of their products. It is evident that while true septicemia emphasizes the actual presence of bacteria in the blood itself, sapremia depends largely upon the limitation to the point of introduction and the destruction of tissue there, while this disease is due to the absorption of the products from the original point of infection. An infection sufficiently virulent to introduce the bacteria directly into the blood would cause true septicemia, but if the tissues had sufficient resiliency to prevent this the infective agency might still remain *in loco*, producing by its action on the tissues ptomains which, being absorbed, produce sapremia.

Sapremia is often ushered in with a single chill followed by fever and sweat, tenderness and pain at the infected spot, or if the wound be under observation it will appear swollen with inflamed edges by unhealthy granulations. The severity of the symptoms largely depends upon the degree of toxicity and activity of absorption in and about the affected area. The skin is hot, the pulse and respiration rapid, tongue dry and thickly coated, urine scanty and highly colored, patient restless with a mild delirium. This will last for four or five days and the symptoms gradually subside.

The older authors were glad in such conditions to see the surface of the wound covered with what they called "laudable pus" and to find healthy granulations. We now know that this betokens a power of resistance of the tissues, a throwing off of the bacterial products and consequent lessened absorption.

It is in obstetric practice that this form of disease is too often found. The odor of the lochia, the tenderness over the uterus, with the general symptoms appearing about the fourth day after delivery, give us warning of infection. The lesion being in great part local, a thorough cleansing with frequent douching will at once ameliorate the symptoms and shortly, if taken in time, the constitutional involvement will also rapidly lessen. In fact, the whole course of sapremia emphasizes the local element, and to local treatment we must look for its removal.

In certain lamentable cases the disease is not recognized in time but is allowed to go on until the patient is overwhelmed by the ptomain poisoning, death occurring from the profound typhoidal depression. We can not too strongly emphasize that the localizing symptoms point to radical local antiseptic treatment. In the obstetric practice referred to, a good douche of bichlorid of mercury will often evert a most threatening condition, but if this is not sufficient a thorough curetting of the uterus, afterward swabbing with tinct. iodin, may be necessary.

Especially after miscarriage the patient may be in ill health for months, with subinvolution of the uterus; apparantly caused by minute shreds of decomposed membranes or clots readily removed by the means indicated, and we believe some of the cases of tubal disease might be prevented by a recognition of the pathology of the ptomain poisoning of which we are now speaking.

The constitutional condition requires a stimulating and supporting therapeusis and regimen.

Pyemia.—There are very few terms in surgery so confusing as the name pyemia. It has been used by different authors to include all the varieties of traumatic fevers referred to, while it is recognized that some of the symptoms were only seen in rare cases. It seems to me we can safely restrict the terms to a distinct disease characterized by a state of depression common to all typhoidal conditions but distinguished by the formation of pus cavities in different and widely separated parts of the body. No tissue may be exempt. Abscesses have been found in the lungs, liver, kidney, joints, muscles, bones, brain, lymphatic glands; coagulability of the blood is diminished, and there is leucocytosis with purulent effusions into the serous cavities. The disease is contagious, being communicable by instruments or sponges in the hands of the surgeon or other attendant and passes along the vascular or lymphatic channels.

It is evident that there is here something different from what we have denominated true septicemia; the constitutional involvement being even more grave and the metastatic abscesses being added thereto.

There is here surely a double infection, the micro-organisms of putrefaction and of pus both being introduced directly into the blood, and the latter proliferating wherever they happen to lodge. It is this double infection which induces the grave constitutional conditions while the local presence of the pyogenic germs causes the abscesses. Fortunately such a combination is rare under the existing antiseptic methods.

The symptoms appear about the second week after an injury. The are, repeated chills and colliquative sweats, the temperature rising synchronously with the chill, the pulse and respiration rapid and weak, with skin icteroid, anorexia, more or less diarrhea, great prostration, and great pain at the immediate seat of the abscess, with hyperesthesia of the cutaneous surface, and erythematous rashes and ecchymoses; the mind being clear unless metastatic masses lodge in the brain.

We can differentiate it from true septicemia by the mental clearness, the hyperesthesia, the repeated chill (half a dozen a day) and excessive exhausting sweat, and the localized abscess.

From intermittent fever we may separate it by the limitation of the paroxysms in the intermittent to a certain day or even hour, by their singularity as a rule, and by the regular succession of the three stages of chill, fever and sweat; compared with the many paroxysms without definite rule throughout the day in pyemia and the fever stage coinciding with the chill and quickly followed by the exhausting sweats. It is thus seen that pyemia, though accompanied by high temperature has no distinct fever stage, the rise of temperature coinciding with the chill. The sweat rapidly follows.

The treatment is supporting and stimulant with early evacuation of abscesses where accessible. Antisepsis and asepsis has almost abolished this dreadful disease, which in former times was indeed "the opprobrium of surgery."

Arterial pyemia, so-called, is an entirely different condition, being non-infective, depending upon the lodgement of an embolus detached from a fibrinous white thrombus in the left ventricle, in some distant organ. The term should be abandoned.

1626 Mount Vernon Street.

DISCUSSION.

Dr. George M. Sternberg of Washington—It seems to me that if pyemia is the result of septicemia you must have your septicemia in the circulation generally distributed in advance of your multiple abscesses and when the abscesses are formed you then have a suppurative fever. I know that pyemia is recognized as a distinct disease, but to me it seems to be a sequela of septicemia.

Dr. E. W. Holmes—That question involves a very large question which the pathologist must settle. It depends upon the question as to which germ produces pus. It is quite possible that the germs that produce sapremia may be the same germs that produce the pus condition, but on the other hand I do not think that Dr. Sternberg is prepared to say that every condition in which pus is produced in the body produces pyemia. So far as we now know if such a condition exists it is simply because we are not yet straightened out as to the exact condition in which pyogenesis may be produced.

A Cause of Myopia.—The prevalent doctrine that myopia, astigmatism and kindred disorders depend upon the physical fatigue of the eye leads us to the consideration of the size of the type used in reading, rather than the intensity of the illumination of the printed page. No type less than 1.5 millimeters in height should leave the case. Ordinary daylight, white rather than yellow for artificial illumination, and white rather than tinted paper round up the advice.

LIGATION OF THE DORSAL VEIN OF THE PENIS FOR FUNCTIONAL IMPOTENCE, WITH A REPORT OF FIVE CASES.

Presented to the Section on Surgery and Anatomy at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY J. A. MURRAY, M.D.
CLEARFIELD, PA.

In reporting these few cases to the ASSOCIATION I am not presumptuous enough to claim priority of discovery for the operation. Surgery has advanced so far that, apparently, there are few operations that some one has not done in the recent or remote past. So with this, it may have been done by many surgeons and abandoned. I have seen no literature on the subject, pro or con. If there should prove to be any virtue in the operation I desire to say that I got the idea from the Materia Medica of Dr. Bartholow, in which these words are used: "It has lately been asserted that deficient erections and loss of the capacity for coitus are not infrequently due to enlargement of the dorsal vein of the penis and consequent too rapid emptying of the veins of the erectile tissue. Acting upon this plausible suggestion, the author has practiced the hypodermic injection of ergotin about the dorsal vein of the penis and has had apparently excellent results."

I have operated on only five cases, four of which were followed by a permanent cure, the other being a complete failure because it was unsuitable for the operation.

From this small experience I am encouraged to believe that when functional impotence is due to an enlarged dorsal vein in men with strong sexual desire, who fail in sexual intercourse on account of imperfect erections due "to too rapid emptying of the veins of the erectile tissue," ligation offers good prospects for a permanent cure.

In neurasthenic cases when the genital organs are small, pale, flabby and relaxed from excessive masturbation, with no sexual desire, the operation would be unavailing, and therefore contraindicated.

I submit a brief history of my five cases, hoping those with larger opportunities in this direction will try the operation on suitable cases and report their success or failure through the columns of the JOURNAL OF THE ASSOCIATION.

Case 1.—A merchant 63 years of age, well preserved, hearty and robust; strong sexuality, during his whole life indulged a great deal in sexual intercourse, some times excessively; father of several children. One year ago married his second and present wife, a strong, healthy, active young woman, 22 years of age. On the first attempt at coitus he met with his usual former success, but the night following this when he attempted intercourse the erection was feeble and lacked intromittent power. Each succeeding attempt for a period of three or four weeks was also a failure; then his condition began to prey upon his mind. Ashamed to consult a home physician he flew to the different "lost manhood restored" advertisements and tried some of the most glaring and reassuring, and was swindled alternately. Then he went to some distant sanitarium and was treated some time with no better results. He was next worked by some medical company who sold him some sort of a suction apparatus for "restoring weak and flabby erections in men with waning power and resultant impotence."

But after all his treatment and instrumental manipulations his condition was worse than in the beginning. At this stage he drifted into my care, impatient and despondent, having given up all hope of regaining his former virility.

I made a thorough examination and found well-developed genital organs; never had gonorrhea nor masturbated to any extent; no stricture; no sensitiveness in the prostatic urethra nor at the neck of the bladder. The only abnormal condition was a very large and tortuous dorsal vein. I advised the injection of ergotin, to which he readily consented. I continued this for three or four weeks and his condition improved somewhat, but his erections were still feeble and unsatisfactory and the organ was swollen, discolored and tender from the injections and I abandoned them.

It was at this juncture it occurred to me that if the constringing influence of ergotin was beneficial why not get an immediate and permanent result by ligature. I examined a long line of text-books but found no enlightenment on the subject; nevertheless I concluded to attempt it, as the patient was anxious to try any measure that held out some hope of cure.

The penis and surrounding parts were thoroughly disinfected and the operation done aseptically under the anesthetic influence of a hypodermic injection of cocain. A short longitudinal incision was made through the skin and subcutaneous tissue, down to the dorsal vein, which was then picked up and ligated in two places, and then cut between the ligatures. The first ligature was scarcely tied till the penis began to fill up and before I had completed the operation he had a powerful erection, which alarmed both him and myself. The organ was so distended and engorged that it was cyanotic in appearance and apparently the smallest capillaries in the glans stood up prominently. Crushed ice was applied constantly; bromids and other depressant remedies were administered. Notwithstanding this, during a period of three days and nights he experienced a constant, powerful and painful erection. Subsequently it partially subsided, but on the slightest manipulation it would become strongly erect, this latter condition existing until the ligatures came away on the fifth and sixth days. In a few days the wound closed. He was so self-confident and enthusiastic that he begged me to allow him to have intercourse with his wife on the tenth day after the operation. I positively refused to consent until two weeks more, but the strain was too great for him and on the fourteenth day he cast my advice to the winds and had coitus with his wife twice and once on the succeeding day. Since that time, which is almost three years from date of operation, coitus has never been attended by failure. He has one child by his young wife and to this day is one of the happiest of men.

Case 2.—A clerk, 27 years of age, had practiced masturbation from his fifteenth to nineteeth year. Following this he very frequently toyed with one young woman for a period of more than two years, without any gratification of his sexual desires. At the age of 22 he attempted intercourse but failed because the erection was imperfect. He made several subsequent attempts with a like result, because the intromittent power was always wanting. He then consulted me and I found a stricture, caliber No. 19 French, four inches from the meatus, in addition to an extremely tender urethra, especially in the prostatic portion. He denied ever having had gonorrhea. I treated the stricture by gradual dilatation, sedative medication and cold douches to the perineum, and later by iron and bitter tonics. I forbade libidinous thoughts, lascivious associations or any attempt at sexual intercourse during my treatment. After three months I gave him permission to have connection, with instructions not to dally or toy with women but to select one with whom he could have coitus on first appearance of an erection. Like all previous attempts this one failed also. The desire was there but the glans penis would not entirely fill up, remaining soft and unelastic. He came back disheartened and despondent and I suggested ligating the dorsal vein, which appeared rather larger than normal. He readily agreed and under cocain anesthesia by hypodermic injection I ligated the vein as in the foregoing case. The first ligature was no sooner tied than the glans penis began to distend and it was only a few seconds until he had a powerful erection and I feared a repetition of the symptoms of the first case. The patient was immensely pleased with the result and the mental effect on him was self evident.

The penis was loosely bandaged and the patient put on large doses of potassium bromid. In the course of a hour the erection partially subsided and he suffered no more pain. In dressing or upon the least manipulation the organ would become powerfully erected. Upon the sixth day the ligatures came away and the wound soon closed, and it was only a few days until the young man was very anxious to try his powers, feeling yery confident he would not again fail.

He was so certain of success that I gave him permission on the fifteenth day to have intercourse but once. He came back in two days the most elated young man I have seen, stating that he had had coitus with a young woman five times in two days. He is married now and he lately told me his erections have always been satisfactory since the operation, which is more than two years ago.

Case 3.—A tanner, [illegible]ed. [illegible] onanism from his seventeenth to his twenty-first year, but not excessively. Has strong sexual desires. Fondled with the object of his affections for more than two years before marriage without any gratification of his passions. Has never had sexual intercourse but frequently experienced nocturnal emissions. Married ten days ago and has not been able to consummate the marriage rite because the erections were feeble and lacked in intromittent power. By careful examination no stricture was detected but there existed a very hyperesthetic condition of the urethra, especially sensitive in the prostatic portion. A steel sound was passed twice a week for a period of twenty-one days, and he was instructed not to fondle his wife nor occupy the same apartment with her.

At the end of three weeks, the hyperesthesia of the urethra had been very much improved; I ligated the dorsal vein, although it was not enlarged. He was strictly enjoined not to attempt coitus for another month. At the expiration of this time intercourse was performed successfully and he has never experienced any difficulty since that time, now more than a year ago, in commanding an erection.

Case 4.—A bookkeeper, 31 years of age, who had masturbated for 7 years, on an average of twelve times in a week. Three years ago he abandoned masturbation and has since suffered from frequent nocturnal emissions, although he had not experienced an erection for many months and had no desire for sexual intercourse. His genital organs were small, pale and flabby. He was anemic, weak and neurasthenic. He had read "lost manhood restored" literature until he believed he could never be cured. I was convinced of that, but did not express it. He was a typical sexual hypochondriac.

On examination I found a stricture, caliber 18 French, four and one-half inches from the meatus, in addition to an extremely sensitive urethra, especially about the neck of the bladder. Under gradual dilatation the stricture and sensitive urethra were cured. With tonic treatment, cold douches to the perineum and good hygiene, his nightly emissions ceased in number and his confidence was somewhat restored. Although he was not a proper case for operation, I ligated the dorsal vein, more for the mental effect I hoped it would have than any hope of permanent cure. His condition did not improve. The bad habits of his past life so preyed upon his mind that he became more gloomy, disheartened and despondent. He drifted out of my care and left the community, therefore his subsequent history was lost, but I feel satisfied the operation did him no good.

Case 5.—School teacher, 25 years of age, unmarried; had practiced masturbation from his fifteenth to his nineteenth year; suffered some from nocturnal emissions; has well-developed genital organs. No stricture, no hyperesthesia of urethra. He had attempted coitus on frequent occasions but they were all attended by failure on account of feeble erections. He was in robust health and had strong sexual passions. Was engaged to be married in a few months but his impotent condition so preyed upon his mind that he was on the eve of breaking the engagement when he consulted me. The dorsal vein being large and prominent I suggested ligating it and explained the theory. He readily consented and the operation was performed. I warned him against dallying or toying with women and advised him to marry his betrothed at once. He did so and all attempts since then at sexual intercourse have been crowned with success.

In conclusion I wish to state that under proper treatment, long continued, Case No. 3 would, I believe, have recovered without the operation. In the foregoing cases, excepting No. 4, the mental effect of the operation was simply wonderful. They felt positive they were cured and wanted to try their powers at once. Two of them were restrained with difficulty. We see so many cases of impotence due only to a fear of sexual incapacity. If we can restore confidence in this class of patients there is very little trouble experienced in establishing a cure, and I am inclined to believe a great many cases of psychic impotence can be cured by ligating the dorsal vein of the penis.

London's Growth.—Returns show that over 1,200 houses are erected monthly and from August 1896 to August 1897, 14,531 houses were built. Alterations and additions are not noted.

GANGRENE OF THE FOOT DUE TO UTERINE MYOMA.

Presented to the Section on Surgery and Anatomy, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY STEPHEN H. WEEKS, A.M., M.D.
PROFESSOR OF SURGERY IN THE MEDICAL SCHOOL OF MAINE.
PORTLAND, ME.

The case which I am about to report is so unique in my experience, that I deem it worthy of publication.

Mrs. M. came to the Maine General Hospital with the following history: During the fall of 1895 and the early part of the winter of 1896 the patient suffered from severe cramps below the knee. It was mostly after sitting for a long time or after sleeping at night. In March, 1896, a slight cold was taken and she suffered much pain, which seemed like the pain of rheumatism. She soon became lame and suffered more pain in the limb, which could be relieved for a time by the application of dry heat. In the early part of June, the limb was so painful and lame that she was obliged to lie in bed. The limb became badly swollen and in the middle of June the weight of the body could not be borne upon it. The sharp pain had changed to a burning sensation and the limb had a heavy "blocky" feeling. The limb was very cold, but when heat was applied she could not feel it. At this time the pain was so severe that sleep was an impossibility. The 3d of July she had what her daughter called a shock. There was complete prostration for several hours. It was three or four days before the feeling of numbness passed away.

At this time the foot was badly swollen, purple spots appeared, as if the foot was cold; these spots would disappear by rubbing and the natural color would return. By the middle of July the top of the foot was discolored and water-blisters appeared. The burning sensation was very severe, the blisters increased in size and number while the toes were very cold and seemed dead.

This condition continued to increase until two thirds of the foot became gangrenous. In the latter part of July, 1896, I saw the patient in consultation with the attending physician. She was a woman 47 years of age, fleshy, and had had one child, daughter, about 20 years old. She had enjoyed good health up to the time of this sickness. There was no disease of the kidneys, and no evidence of arterial degeneration.

On examination I found, what her physician had discovered some time before, a fibroid tumor of the uterus, rapidly growing, with thick and rigid abdominal walls pressing the tumor firmly against the iliac vessels. It was the right foot that was gangrenous, and the history showed that she was most comfortable when lying on the right side, and this was the position which she had occupied the most of the time while in bed. The case seemed well nigh hopeless. The woman was weak and almost helpless from her long sufferings, the tumor of the uterus was large and rapidly growing, the gangrene, while not rapidly extending, had destroyed nearly the whole foot. In this condition she was brought to the Maine General Hospital, Aug. 3, 1896, as my private patient. She was kept in the hospital one week before the operation for rest and preparatory treatment. At this time two-thirds of the foot were dry and mummified and the line of demarkation was well-formed.

August 10, one week after her admission to the hospital, I removed the tumor including the uterus and its appendages. The patient made a rapid and uninterrupted recovery from the hysterectomy, and in two weeks from the first operation, I amputated the leg at the junction of the middle with the lower third by Teale's method. This wound healed promptly by first intention without a drop of pus or a blush of redness. She left the hospital in five weeks from the time she entered, with the wounds entirely healed and rapidly gaining in strength. In about three months after she went home she was fitted with an artificial limb, and at this time, nine months after the operation, is entirely well.

As this was the first case of the kind I had ever seen I was anxious to know what had been the experience of other surgeons, consequently I wrote to the National Bureau of Medical Bibliography at Washington, and received the following reply:

WASHINGTON, D. C., Feb. 26, 1897.

Dear Sir:—In response to your letter of the 18th inst., we send you herewith reports of all the cases of gangrene of the lower extremities resulting from uterine fibroids that we have been able to find. We made an exhaustive search through all the literature of gangrene, cases of, and tumors, uterine, complications of, without finding any additional cases."

Pott's Gangrene from Ovarian Tumor.—Dr. Henry Fitzgibbon. (*Brit. Med. Jour.*, Lond., 1876, I, 116.) Dr. Fitzgibbon gave the history of a case of Pott's senile gangrene which had run to an unusual course; and exhibited the specimens. A female, upward of 70 years of age, was admitted into hospital in March, 1875, with gangrene of the fourth toe of the left fort. The case presented the usual symptoms of the disease as described by Pott. Her bowels were constipated, and there was a tumor in the left iliac region, which was believed to be due to an accumulation of feces. Treatment based upon this diagnosis produced a marked diminution in the size of the tumor. The disease extended in the foot (which, however, preserved a higher temperature than the unaffected one) to the ankle-joint, when suddenly the pain ceased, and the foot recovered, the toes alone becoming mummified, and consequently separating. It was ascertained that the abdominal tumor, which was still perceptible, had an old history; and the patient informed Dr. F. that she had been under treatment some years previously for an "uterine tumor." She was discharged in good health after being six months in the hospital. Five months subsequently she was readmitted. Her whole foot then looked gangrenous; the disease extended rapidly up the limb; she had black vomit, great abdominal pain, and died. A large densely fibrous tumor of the left ovary was found lying on, and pressing upon, the common iliac artery. The heart and vessels down to the line of demarkation, which had formed midway between the ankle and the knee, were healthy. Below this there were some plates of atheroma in the posterior tibial artery. Dr. F. believed that the circulation in the left lower extremity had been interfered with by the pressure of the tumor on the iliac artery, which was increased by the accumulation of feces also exerting pressure in the same direction. The removal of the latter factor by treatment allowed the partial recovery in the first instance; and a recurrence of pressure from a reaccumulation of feces, occasioned, he considered, a recurrence of the disease.

Gangrene of Leg; Polypus Uteri and Removal; Amputation.—J. Cooper Forster, M.D. Guy's *Hosp. Rep.*, London, 1875, 3, S, XX, 79.) Mary B., aged 45, widow, was admitted into charity ward on Dec. 31, 1873. Family history good, always had good health. Fourteen days ago, in the night, her foot got cold and ached; next morning all the toes of that foot were quite white and cold; she used a liniment and wrapped the foot up in warm flannels. In eight or ten days the toes began to get black; this spread along the foot and up the leg. She has not been exposed to great cold, but generally loses a large quantity of blood when menstruating.

On admission.—Is delicate looking; the toes, dorsum of foot, and front of lower half of right leg, are quite black and cold, and she has very little feeling in those parts; femoral artery normal. She has also a large growth occupying the region. Leg dressed with carbolic acid and wrapped in cotton wool.

January 8. Chloroform given. Dr. Phillips removed a polypus which was attached to uterus near os. It was very nearly as large as the head of a fetus, and was cut away by scissors; no bleeding.

January 19. There is a well-marked line of demarkation on leg; the gangrene has not spread since she came in, but there is some discharge from it.

January 20. I amputated through the knee-joint; anterior and posterior flaps made; Esmarch's bandage used; scarcely any bleeding.

January 23. Stump dressed under spray; then wrapped in gauze soaked in carbolic oil and a back splint applied; there is rather a free discharge.

January 28. Dressed as before. Stump has begun to slough. She suffers from cough and expectorates a good deal of thick mucus.

February 6. Now has a bed-sore on right buttock, about 4 inches by 3 in size, and filled with slough; lies on a water bed. Discharge less and of a healthy kind.

March 3. Stump nearly healed, bed-sore looking better, sits up a little daily.

March 9. Two other bed-sores appeared. No albumin in urine, appetite bad, looks anemic.

April 6. Confined to bed again and takes very little food.

April 20. Suffers from diarrhea. Sores looking more unhealthy, and increasing in size. Takes no meat now.

May 12. Lives almost entirely on brandy and milk. Bed-sores continue to look very unhealthy.

May 21. Died this morning.

Gangrene of the Right Leg.—Amputation. Death fifty-one hours afterward. Large fibrous tumor of the uterus compressing the iliac vessels, (old disintegrating clot in left auricle, (embolic) obstruction of abdominal aorta and iliac arteries with coagulum. Case under care of Mr. Hulke. (*Med. Times and Gazette*, London, 1863, II, 142.) A sallow, dark complexioned woman, aged 55, was admitted into Middlesex Hospital, Bird Ward, April 1, 1863, with moist gangrene of the right leg, which terminated abruptly by a distinct line at the knee. For a short distance above this, particularly in the ham, the tissues were edematous, and the skin had a slight dusky, purplish tint, from stagnation of the capillary circulation. Severe pain in toes. Lower part of abdomen contained a solid oval tumor lying across the middle line, and reaching nearly as high as the umbilicus. Both in front of it, and in the flanks, percussion elicited a clear sound. The liver was not enlarged. The urine was free from albumin. There was no edema of the left thigh or labia. The heart acted very irregularly, four or five beats, then an intermission, then a double beat—so that the pulse could not be accurately counted; it was estimated at 120; no bruit indicating valvular disease was noted. Her general condition was one of great depression.

She stated that since childhood, when her left leg was amputated for white swelling, she had never had any grave illness till last Christmas, when, not feeling well, and discovering the tumor in her abdomen, she underwent a course of treatment for a supposed abdominal dropsy. After pursuing this for a fortnight, in the middle of January a bleb appeared on the instep, which was followed shortly by a discoloration that gradually crept up the leg.

Her temperate habits, apparent freedom from organic heart-disease, and from disease of the kidneys, made it improbable that the gangrene had a constitutional origin; while the suddenness of its occurrence strongly pointed to a local origin, and this Mr. Hulke thought might be the compression of the right common iliac vessels by the uterine tumor, and their consequent obstruction with coagula.

On the following day after admission amputation was done in the lower third of the thigh. There was little bleeding, the main vessels being plugged with coagula. At 10 o'clock, same evening the operation did not seem to have added to the patient's depression. Pulse 100; sleeping; had taken beef tea and tablespoonful of brandy every hour. Next day stump had shrunken much. There had been free oozing of serum from it and there was a want of action, but no appearance of an extension of the gangrene. Continued to take nourishment. Toward evening restlessness and sickness came on, pulse rose to 120 and she died on the evening of the second day.

At the examination of the body a large fibroid tumor of the uterus was found, consisting of several lesser and two principal masses. Of these larger masses, one was connected with the back of the uterus and filled the pelvis, flattening the rectum and bladder. The other sprang from the fundus uteri. It measured more than 7 inches in diameter and lay upon the promontory of the sacrum and lower lumbar vertebræ, over the aorta and vena cava. The aorta, for over two inches above its bifurcation, the common, the internal, and the external iliac arteries for half their lengths, were plugged with solid coagula, which were prolonged in a tapering form into the distal halves of the last named vessels, nearly as far as Poupart's ligament. The oldest coagula were those in the internal and common iliac arteries and in the aorta. The distal halves of the external iliac arteries, which were incompletely filled with coagulum, were fully one third smaller in diameter than the proximal halves, which were completely plugged. The superficial femoral artery, for two inches above where it had been divided in amputation, was plugged with a fibrinous clot, above which this and the common femoral artery were pervious, containing only scattered linear clots. Their caliber was diminished. The vein was plugged for the same distance from the face of the stump as the artery. Above the clot it was distended with black, treacly, fluid blood. The external, internal and common iliac veins, and the vena cava inferior were empty and collapsed. Many of the tissues of the thigh were edematous. Small vessels were plugged, and examination of the limb showed that the popliteal artery and vein were plugged as far as their division, beyond which the disorganized state of the tissues prevented their being traced. The ureters and pelves of the kidneys were dilated, evidently from the uterine tumor damming back the urine. The lungs were edematous, their anterior and lower borders were emphysematous, and their apices bore puckered scars. The heart was large and flaccid; its right side and left ventricle contained yellow jelly-like fibrinous clots, but the appendix of the auricle enclosed an old clot which adhered firmly to its walls. The exposed surface of his clot was cheesy, friable and rough, whil [illegible] interior [illegible] roken down and pulpy. Although di [illegible] as w [illegible] no distinct and separate emboli were distinguishable in the coagula contained in the aorta and iliac arteries, it is likely that the infarction of these arteries began by the interception of portions detached from the disintegrating clot in the heart, at those points where the arteries were narrowed by the pressure of the uterine tumor.

The method of hysterectomy which I have employed for many years and which is entirely satisfactory is as follows: The patient is prepared for the operation in the usual way. Just before the operation, immediately preceding the administration of ether, a pint of warm water with four ounces of wine is injected into the rectum. This is absorbed during the operation and supplies, in part at least, the blood lost during the operation and prevents shock, which is liable to occur when much blood is lost. I consider this a great safeguard against exhaustion following any prolonged operation where there is likely to be a considerable loss of blood. I always use the catgut for ligatures and sutures, and much prefer it to all others. The catgut which I use is Am Ende's No. 8. The morning of the operation the catgut which is to be used is sterilized by putting it into 95 per cent. alcohol in a wide-mouthed bottle, the stopper being loosely put in, the bottle is put into an Arnold sterilizer, where it remains about ten minutes—the bottle must be full of alcohol and not allowed to boil down and expose the catgut. If necessary, alcohol must be added, in order to keep the catgut covered, otherwise it will be spoiled by the heat.

Am Ende's catgut, prepared in this way, I consider perfectly sterile and feel safe in using it in all abdominal operations. To my mind the absorbable ligature is immensely superior to the silk which is generally used. I have used it for twenty years in all my abdominal work and I have never regretted it. It does not slip if properly used, it is not absorbed too soon and to me it is a great satisfaction to feel that the ligature will be absorbed in two or three weeks and no foreign body is left in the cavity or wound.

All things being ready, an incision is made in the usual way large enough for the removal of the tumor without too much stretching of the tissues. I think a mistake is often made in trying to work in the abdominal cavity through an opening altogether too small. Much more harm is done in this way than would result from a slight increase in the length of the incision. After the tumor is exposed a large curved needle armed with a strong silk ligature is thrust through the fundus of the fibroid and the ligature drawn through and formed into a loop, and this is used for making traction. By the aid of this loop the tumor is slowly and carefully drawn out through the opening and gradually pulled up so as to stretch the broad ligaments and vagina and thus secure as much tissue for the pedicle as possible.

Sterilized gauze is now packed around the tumor to prevent the intestines from protruding and to protect them from injury. This step having been taken I am now ready to commence the removal of the tumor, including the uterus and its appendages.

A pair of large curved Spencer Wells forceps grasp the broad ligament below the ovary. Instead of the forceps a strong silk ligature may be used. After the ovarian artery has been secured in this way, a curved needle armed with No 8 catgut prepared as above directed is passed through the outer edge of the broad ligament one inch or more below the Wells clamp or silk ligature, taking in as much tissue as can be securely tied and no more. If too much tissue is included in the first stitch the ligature is liable to slip when the tissues are divided and troublesome hemorrhage will occur.

I consider this precaution very important. The ligature is drawn through, leaving eight or ten inches of the distal end of the ligature to use in tying as the operation goes on. The ligature is tied very firmly and a second stitch is taken and before it is tighened the tissues are divided far enough above the catgut suture so that there shall be no danger of the tissues slipping through the loop of suture; and the cut extending up to but not beyond what is included in the second stitch, then the second looped stitch is tightened and made fast by tying to the distal end, which has been left long for this purpose. This process is carried on step by step, transfixing and tying and cutting, but always keeping the stitching a little in advance of the cutting so that the blood vessels are included in the suture before they are cut. This process is carried on until the uterine artery is included in the stitch and divided. At every step or two the ligature is fastened by tying to the distal end. If this rule is observed there is no possibility of the suture becoming loosened. When one side is secured in this way the operator changes sides with his assistant and the opposite side is tied and cut in the same way. When both broad ligaments are severed down to and including the uterine arteries the cervix is divided in the form of a wedge with the apex downward. Before dividing the cervix as indicated above, a flap of peritoneal membrane is turned down from the anterior and posterior surface of the uterus long enough to cover the stump of the cervix after its division and stitching. This wedge-shaped cavity is closed by bringing the cervical tissue together with the same catgut that has been used for stitching off the broad ligaments. Then a curved needle armed with a smaller catgut, No. 2, is used to bring together the flaps of serous membrame over the stump. When this is completed the divided cervix is entirely covered with peritoneum, leaving but very little raw surface within the peritoneal cavity. The abdominal cavity is now washed out with sterilized water, the abdominal incision closed, dressings applied and the operation is completed. I firmly believe that this is the ideal method of making hysterectomy. I much prefer it to the vaginal route, even for the removal of small growths requiring the removal of the uterus. The abdominal route gives one an opportunity of inspecting the uterus and its appendages and enables the surgeon to better decide what should be done, whether a myomectomy or hysterectomy. If there is malignant disease of the cervix and a hysterectomy is decided upon the vaginal route is to be preferred, as it enables the surgeon to remove the surrounding mucous membrane if it is involved in the disease.

In view of the fact that very many of these tumors are so rapid in their growth as to entail serious risks to life from the compression of other organs, from their interference with the normal functions of life, from the pains and disabilities they entail or from the profound anemia caused by persistent and profuse hemorrhage, it becomes evident that something more than an expectant plan of treatment must be instituted.

While it is true that many women with uterine fibromata go through many years suffering but little inconvenience, there is always more or less danger to the life and well-being of the patient. There is danger of cystic degeneration, which takes away the hope of total disappearance by involution. There is also danger of the occurrence of septic infection with suppurative and gangrenous processes threatening the life of the patient. Growths springing from the cervical portion and extending between the layers of the broad ligaments occasion early and severe symptoms from pressure upon adjacent pelvic viscera. Submucous growths have a special danger from the hemorrhages which they induce. Sarcomatous degeneration of fibromyomata has been reported in a number of instances. It must be acknowledged that the prognosis of a growing fibroid is always a serious one. Such a growth is liable to cause death through the exhaustion consequent upon renal, cardiac or digestive disturbances; through the prolonged anemia or finally through septic or malignant changes in the tumor itself. In a large proportion of cases in which life is not destroyed the presence of these growths very greatly restricts the usefulness of the patient, prevents her from gaining a livelihood and entails upon her a prolonged condition of invalidism.

In view of these facts as stated above and in view of the less mortality which follows hysterectomy in the hands of competent operators, I believe the operation should be performed much more frequently than has been recommended by many surgeons. At the last International Medical Congress, Martin of Berlin affirmed that the total extirpation of the uterus would soon be accepted as one of the principal operations for the surgical treatment of uterine fibromata. Martin's series of twenty-six cases presented only one death—a mortality of 3.8 per cent.; Ott, twenty-four cases with one death; Bantock, twenty-three cases with one death; Carle, twenty cases with one death; Zweifel, ninety-three cases with three deaths; Leopold reports twenty cases with no death, and mentions Brennecke's report of nineteen cases with no death, making in all 225 cases with six deaths—a mortality of 2.6 per cent In Europe, five years ago, the mortality shown by the same class of operators was 25 per cent., while now they show a mortality of less than 8 per cent. In the United States, where the tendency is toward the operation of complete hysterectomy, in 281 united cases, three years ugo, there were but 22 deaths—a mortality of but 7.8 per cent. I have no doubt that the mortality is considerably less at the present time than it was three years ago. If this paper shall be the means of calling out a free discussion of this important subject, and shall cause to be put on record other cases of a similar nature I shall feel amply repaid for the labor in preparing it.

GYNECOLOGY IN BERLIN.

A. MACKENRODT.

BY JOSEPH RILUS EASTMAN, M.D.
INDIANAPOLIS, IND.

A. Mackenrodt is especially notable for his originalness. As a younger member of the Berlin Gynecological Society, he shies his castor with unaccustomed aggression before his seniors in age and rank, and is therefore unpopular. It was Mackenrodt (Dührsen to the contrary notwithstanding) who introduced the ill-fated vaginal fixation for uterine retrodisplacements. He is the only continental exponent of igni-extirpation for carcinoma uteri and of bloodless enucleation of the uterus for intractable postclimacteric inflammations and smaller fibromata. Under the impulse of the condemning reports of Paul Strassmann and others who had confined women with vaginally fixed uteri, "Mackenrodt's operation," after a short life, was relegated, as is well known, to comparative obscurity. Dührrsen still defends it qualifiedly, and the writer has seen A. Martin make the operation repeatedly and recently, but Martin places the uppermost of the three sutures not higher than a point four and one-half centimeters below the vertex of the fundus uteri. Mackenrodt himself having been driven to sectio Cæsaria after vaginal fixation in plural instances, forsook the method, convinced of its unfitness by the testimony of his own experience.

In its stead he is developing a new operation, a vesico-fixatio, by which it is sought to fix the fundus of the uterus over the fundus of the bladder by means of a flap of the latter's peritoneum. He shows by charts and frozen sections that the proversio-flexio so secured and maintained corresponds closely to the normal anatomic position. Two women operated on by this method have borne sound children at term. The technique is as follows: With the patient in the back posture, the anterior lip of the portio is seized with a double tenaculum and drawn forward and downward as for anterior colporrhaphy. A split is then made through the anterior vaginal mucosa, extending in the median sagittal line, from the anterior utero-vaginal junction forward, half way toward the meatus urethræ. The septum vesico-uterinum and the vesico-uterine reflection of peritoneum are successively exposed and divided transversely. The tenaculum in the anterior lip is then replaced by a guy ligature, and the portio is pushed upward and backward to force the vagina conversely forward and downward. To bring the fundus into the vaginal incision double tenaculæ are used. With these one "climbs" upward along the anterior uterine surface, applying each higher than the last, until the vesical peritoneum, which has been peeled loose as high up as possible, may be laid flap-like over the fundus uteri and stitched fast. The peritoneum is drawn as a curtain between the operator and the fundus, the stitches being applied into the latter "through the curtain." The fundus is now released and the anterior vesical flap of the septum vesico-uterinum is sutured into the muscular uterus as high up as the internal os, a centimeter higher than its anatomic attachment, to the end that the fundus may be held more securely forward. An adhesive peritonitis is expected to provide permanent fixation.

In a communication to the *Centralblatt für Gynecologie*, 1895, No. 6, Mackenrodt took the position that adequate use of the glowing cautery offers the only hope for improvement in the statistics of lasting results after extirpation for carcinoma uteri. He recommended that the entire operation be made with the cautery, that the entire wound surface be charred, the goal sought being prevention of inoculation infection. He maintained that even in that instant when the tissues are divided, the wound surface must be protected against the invasion of cancer germs, and that such protection is only possible when all dissecting is done with the Paquelin. "Methods in which the cautery supplements the knife, ligature or clamp are illusory." In an experience of thirty igni-extirpations, Mackenrodt claims not to have had a single recurrence, the post operationem period of observation varying between one and two years; nor was any patient lost from shock.

Having found by experiment and observation[1] that even the largest blood vessels may be safely sealed by the Paquelin in that instant when they are severed by the same. Mackenrodt went a step farther and said "all hemorrhage must be checked by the charring cautery," and that clamps used during the operation to protect the surrounding tissue may be removed directly the operation is finished. The possibility of closing the uterina and spermatica he adds, however, is only present after a provisory application of suitable clamps (wing-jawed like the Langenbeck hemorrhoid clamp, shovel-shaped and curved on the flat), with which the stump to be treated may be emptied of blood and charred, without injury to the urethra, rectum or bladder.

The vaginal igni-extirpation after Mackenrodt is made as follows: After thorough cleansing of the vagina, curettement and cauterization of the exposed carcinomatous foci, the field of operation is disinfected with alcohol and sublimate. If the vulva is small a lateral incision is made with the cautery into the perineum. The portio is then seized with strong double tenacula, drawn downward and forward, and with the Paquelin the posterior vaginal wall is separated from the collum, and the cavum Douglasii opened. The vaginal wall is next burned off laterally, and lastly anteriorly from the uterus.

The connective tissue between the bladder and the uterus and ligamenta lata is now put upon the stretch by the thumb of the left hand pressing against the anterior vaginal wall, In dividing these connections the Paquelin is drawn from left to right in repeated strokes, the tissues giving way in the direction of least resistance, exposing the anterior aspect of the uterus and broad ligaments. The shovel-shaped clamps are now applied to the broad ligaments, their concavity toward the uterus. The stumps on each side are successively burned through and charred to the surface of the clamps. The clamps are removed and the remaining connections between the bladder and uterus are divided in the manner described above. The peritoneal cavity having been opened anteriorly, the left index finger is passed through the opening, over the crest of the right broad ligament, and a clamp is reintroduced and made to embrace the remaining peritoneal portion of the stump. The latter is then divided with the cautery. Lastly, the clamp is applied to the left ligamentum latum, the stump divided and the uterus removed. Iodoform gauze is placed in the peritoneal opening to prevent the decensus of intestines and the perineal incision is sutured up.

Mackenrodt is a warm advocate of Battey's colpotomia posterior. He practices the operation himself and has done much to bring it into new favor. He prefers the posterior to the anterior vaginal section, because of the former's simplicity and safety of principle.

During the last few months he has removed all uteri demanding radical operation for other conditions than malignant neoplasms and large fibroids by enucleation. In the majority of cases he is able to accomplish this without the use of a single ligature. Occasionally, however, he ligates the ovarian artery. The technique is the simplest possible. He seizes the portio with a double tenaculum, and with a pair of short curved scissors makes an annular incision through the vaginal vault at the utero-vaginal junction. He proceeds upward, clipping with the scissors in the endopelvic fascia, until the uterus is freed.

Delaware and Vermont Streets.

LEPROSY OVERCOME BY ISOLATION IN THE MIDDLE AGES.

BY ALBERT S. ASHMEAD, M.D.

NEW YORK.

In the Middle Ages leprosy spread in every country of Europe and continued to spread until strenuous efforts were made to bring the diseased parts out of contact with the healthy community. In this no charitable regard was had to the victims of the scourge; the weal of the sane majority alone was considered. It is from this point of view that it behooves us also to judge the conduct of the church. The Order of Lazarus was founded and lazarettoes built in great numbers. The work and purpose of the order were to segregate and govern the afflicted and dangerous part of humanity. The thing was necessary, was an unavoidable consequence of the resolve of healthy mankind to remain so, and it was not so much charity as one might believe. The community wanted this work to be done, and who could do it but the church?

But, according to Dr. Ehlers, Secretary-General of the Berlin Lepra Conference, the church might have been spared these worries and these dangers, for isolation is not necessary, as these Middle Age people believed, who, through isolation, were fortunate enough finally to overcome the disease.

It is not certain that the growth of civilization since the Middle Ages has rendered the spread of leprosy impossible. We cheerfully admit that it can not overwhelm people who are clean in their habits, well separated in their families, careful of their bedding, living in sufficient remoteness from the inferior animals, etc., as it did our ancestors of the Middle Ages, whose life was so very different. Yet some danger still exists, and the spread of leprosy in various parts of Europe, and in parts which I venture to say are cleaner than the leprosy centers of Norway and Iceland, proves that the disease has not lost, under any circumstances, its vital stamina; it seems to stir itself with remarkable vigor, and to be able to take advantage of any elbow room left to it.

If enforced isolation and a permanent committee of official delegates do not come out of the Congress of Berlin—and Dr. Ehlers does not want them to—that Congress will have been held for nothing, or at least only *ad majorem Ehlerii gloriam.*

SURGERY ONE HUNDRED YEARS AGO.

AN HISTORICAL STUDY

BY DR. GEORGE FISCHER.

DEDICATED TO THE GERMAN SURGICAL ASSOCIATION.

TRANSLATED FOR THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION BY CARL H. VON KLEIN, A.M., M.D.

(Continued from page 631.)

XIII.—GERMAN MEDICINE.

Albert von Haller (1708–1777) shone above all others. Born for science, at the age of 8 years he applied himself to Greek and Hebrew dictionaries, outlined a Chaldean grammar and collected the biographies of several thousand celebrated men. While a gay youth he wrote Latin and German satires upon his teachers. At 15 he went to Tübingen to study medicine and in the following year wrote an anatomic polemic against a professor. After a two years' sojourn there he is said to have been expelled because he, with some other students, had made a shepherd so drunk with brandy that he died of the effects. He went to Leyden, where he became the friend of Boerhaave and of the young anatomist, Albin. After his graduation he went to England and France, to Douglas, Cheselden, Jussieu, J. L. Petit and Winslow. In Paris he lived with le Dran for the study of surgery and anatomy. Then he went to Basel expressly to hear Bernouilli's lectures on higher mathematics, which later charmed him so much, that upon his wedding day he employed himself diligently with differential calculus. In 1729 he was a practicing physician in his native city of Berne. The city had an anatomic amphitheater built for him, appointed him director of the hospital and overseer of the city library, where he pursued historic and bibliographic studies, arranged several thousand old coins and at the same time showed great fondness for botany. In 1736 he was called to Göttingen as professor of anatomy, botany and surgery. His fame increased from year to year; the academies endeavored to welcome him among their members; there came calls to Oxford and Utrecht and as president of the Berlin Academy. Although George II. loaded him with favors and obtained for him a patent of nobility from the emperor, after a residence of seventeen years he left Gottingen, chiefly on account of his health, as in his house, which was built on a marsh, he had for a long time suffered from intermittent fever, and had had a severe nervous fever. He had also buried two wives there. The story that he left Göttingen rather out of chagrin, is very improbable; it could not but happen that as a great mind he would be publicly and privately maligned. He went back to Berne in 1753 and accepted a place in the great council and as inspector. There he had to do with agriculture, salt works, sanitary regulations and institutions of learning, and he made many journeys in the interests of the state. Göttingen tried to secure him again, the Empress of Russia to draw him to St. Petersburg, but in vain; he remained in Berne. In the last two years of his life he suffered much from insomnia, but, nevertheless, he worked with ease and lived almost entirely in his library, where he slept and spent long months. He died on Dec. 12, 1777.

[1] After castration of stallions, hemorrhage from the spermatic artery may be checked without ligature, by the application of a red hot iron.

Haller was one of the greatest scholars of his century, and one of the last polyhistors, highly renowned as a physiologist, anatomist, botanist, author, poet and statesman. He carried with him an Alpine load of erudition (Herder). He had as good command of the languages of antiquity as of those of all civilized nations, and was at home even in Tartar and Chinese. It is difficult to say whether one should admire more the variety of subjects treated by him, the thoroughness of his researches, or the power of his judgment to draw conclusions from the mass of facts. Although wife and children, pupils and friends had to help him in his work and he hurried through over 12,000 reviews a day in this way, he has written works of colossal scope, each one of which would require a lifetime, and was without its equal. Among them are his great classic works on botany and anatomy, and the literary history of these subjects and of surgery and medicine. He worked for years on the publication of Boerhaave's lectures, which he supplied with notes, and over which he came into conflict with van Swieten, with whom he was never very friendly. His most important work was his physiology ("Primæ Lineæ Physiologiæ," 1747; the great work "Elementa Physiologiæ," 1757), with which a new epoch begins. In this he laid down his doctrine of irritability, which within a short time superseded all other physiologic and pathologic questions. Hitherto æther had been taken with the principle of the soul to explain the movements of the body, and the doctrine of Glisson (born 1597), that each fiber has capacity to be moved by means of an irritant, seems to have been forgotten. Beginning here, Haller first turned to irritability as an independent power of the muscles, which was the cause of movement and vivified the hitherto dead machine of the mechanics. At first he attributed three kinds of force to the muscles: The dead so-called elasticity; the implanted so-called irritability, which remains only a short time after death; thirdly, the nervous force, which is conveyed to the muscles from without through the nerves. Since irritability remains in an animal that has been killed, and in a heart entirely separated from the body, it can be derived neither from the brain nor from the soul, and the control of the will over it is not to be considered. In this Haller opposed the doctrine of Stahl. In 1752 he laid before the Gottingen society 190 experiments in which in various parts of the body he had demonstrated irritability and nervous force. The periosteum, peritoneum, pleura, ligaments, cornea, callosities, cerebral membrane and tendons he considered entirely insensible; the nerves, on the contrary, sensitive but not irritable, because they do not move at all. Irritability is found only in parts supplied with muscles (and in the uterus); this power is contained in the gelatin which with the earthy component forms the muscle-fiber. It remains a long time in the severed muscle, and those muscles are the most irritable which retain this property longest after death—first the heart, then the intestines, the diaphragm, and lastly the voluntary muscles. With these different degrees of irritability he would also explain the differences of temperament; a high degree of irritability with strength of fibers, was said to constitute the choleric temperament; with weakness of fibers, the sanguine; a low degree, with weakness of muscles, the phlegmatic. The doctrine of irritability forced its way into physiology. When Haller first introduced into this science exact research with experiments, he became the founder of special physiology. He took up all the organs of the body in turn, showed them first anatomically, then experimentally, and finally explained their functions. This method of research, by which he made a mass of discoveries and widened considerably the limits of anatomy and physiology, was at that time entirely new and an extraordinary advance. Haller soon found his followers and opponents. Chief among the latter was Whytt, who considered experiments upon tortured animals questionable; de Haën, who as the most violent of his German opponents, in the end accomplished little; and le Cat, who was decorated by the Berlin Academy, which had announced a prize essay on muscle action. All of the candidates for the prize had expressed themselves against Haller. His principal advocates were Winter, Fontana, Zinn, Zimmermann in Hanover, and Tissot in Lausanne. The doctrine of irritability gradually penetrated into all pathologic discussions, although it was usually misstated, and hence brought about much confusion in the second half of the century.

Haller, the poet, should not be left without mention, since he was one of the first to give a new impetus to the sadly decaying literature. The imposing nature of Switzerland gave him new impressions (his most celebrated poem is "Die Alpen," 1729) and he led poetry out of the study into the open air. At the hand of the British poets he sought an impressive presentation, and his poems, which possessed an unaffected sentiment and deep comprehensive ideas, were considered, throughout a generation, as the correct model. In later years he wrote a romance in which he sought to characterize the forms of government.

A short time before Haller began to teach in Göttingen, *Gaub* (1705–1780) had gone to Leyden as professor of medicine. He was Boerhaave's favorite pupil and for twenty years only made commentations on the Institutions of his teacher, and then for the first time published his own Institutions (1758). For a long time these have been regarded as models, and until the revolution in pathology of the most recent times, they formed the basis of most German Pathologies (Wunderlich). A selector, of the purest water, he wrote with great clearness, although he was not free from inconsistencies, in that often proceeding from a correct principle he would later abandon it.

About this time Boerhaave's doctrines were carried to Vienna by his pupil *Gerhard van Swieten* (1700–1772), and through him the Vienna School was founded. This soon set the fashion in Germany. Van Swieten, born in Leyden, developed such extraordinary industry during his studies that he grew ill and fell into melancholy. Under Boerhaave's tenderest friendship and personal care he recovered and showed his gratitude by refusing a splendid offer from London; with unassuming modesty Van Swieten remained a pupil of Boerhaave until his thirty-eighth year and did not leave him till the latter's death. Since, as a Catholic, he could not hold a professorship in Holland, he accepted, in 1745, a call of Maria Theresa to Vienna. Upon his entrance into the imperial service, the reformation of the medical sciences fastened itself upon the Austrian monarchy. As Perpetual President of the Vienna Medical Faculty, which he found in a lamentable condition, he gave an entirely new form to that body and drew thither various teachers (De Haën, Jacquin, Laugier, Collin, Pallucci). One of his greatest services was the introduction of clinical instruction into medicine in Austria. As chief of the military medical department, he organized the entire instruction in medicine and natural science. Van Swieten had written down Boerhaave's lectures almost verbatim by means of Ramsay's stenography; he then began to publish a commentary on the Aphorisms of his teacher, which were an oracle to him, according to his own statement. He first explained almost every word with exaggerated conscientiousness, and later proceded independently. These commentaries, a work of thirty years' study, won a European reputation in the second half of the century, and were in the hands of all physicians. They were distinguished less for great ideas and new points of view than for therapeutics excellent for that time. In this work lay a peculiarity of the time which arose in the character of the eighteenth century, and is in sharp contrast to our views. It was, among other things, the subordination to authority, the high esteem for it. It is hardly conceivable to us how so highly gifted, original and learned a man as Van Swieten could find his highest honor, for twenty years, in being called the pupil of Boerhaave, as Haller, one of the first scholars of the century, who later did go his own way, did not disdain to publish Boerhaave's lectures. This mania for authority worked the immense detriment of putting brass chains upon free research, against which the advantage of allowing no self-conceit to flourish in the great mass of mediocre heads, went far toward balancing.

When in 1754 the professorship of the medical clinic in Vienna was founded, Van Swieten obtained it for his previous companion in study, *Anton de Haën* (1704–1786), who had sat with him in Boerhaave's lecture room. De Haën became the first clinical teacher of Vienna and of Germany. A captivating eloquence and an ardent enthusiasm for science were united with a rare energy through which nothing was too much for him in spite of his many-sided activity. With these he possessed, unfortunately, a boundless ambition and a high degree of sensibility, and felt himself injured by the praise of other men. He could not bear even the recognition which was given to Van Swieten; only one man he honored devotedly until his death, his teacher Boerhaave. His intolerance made him many opponents. In his fifteen volume work, "Ratio Medendi" (1757), he showed himself chiefly as an empiricist and an enemy of the systems, and endeavored to demolish all newly arisen theories upon empiric grounds. He vigorously opposed vaccination, the general acceptance of which in Austria was impeded many years by his authority, and he was weak enough to defend belief in witchcraft. He esteemed pathologic anatomy very highly, and confessed it openly when dissections disproved his diagnoses. In therapeutics, bleeding and electricity played a large part. His careful researches have brought to light many important observations, whose value, however, he did not always perceive, so that, gradually forgotten by physicians, they had to be discovered anew in more recent times. Among these belong especially his measurements of temperature in the inherent heat of the body.

It is of interest to see what part the previous century has in a method of investigation which has become established in medicine only during the last decade. After Sanctorius (died 1638) first took the temperature of the human body with a thermometer made by himself, a hundred years passed before Boerhaave did the same thing with improved instruments. Van Swieten considered the estimation of the heat by the hand uncertain and measured it according to Fahrenheit, a citizen of Danzig, who had constructed his thermometer in 1731. De Haën took up this method with great energy, applied it to healthy patients. He left the thermometer in the armpit seven and one-half minutes and then added to the degree marked, 1 to 2 degrees, because he had ascertained that the quicksilver afterward rose that distance. He found the temperature higher in the aged, observed the morning remission and evening exacerbation in fever cases and an increased temperature during a chill, which his contemporaries declared the greatest paradox; further, he noted the incongruity of pulse and temperature in many cases, and the frequent contrast between the subjective feeling of warmth and the objective increase of temperature. He adapted his therapeutics according to these variations of warmth and regarded a return to the normal temperature as an evidence of recovery. De Haën remained isolated; the other German physicians did not trouble themselves at all about his measurements. Previously, in England (1740), accurate measurements were made on healthy men and animals, and the Swede, Martin, devoted almost two years to such observations, which he made known in 1764. He found 36 to 37 degrees Cels. as the highest degree of temperature of a healthy person, and stated accurately the variations in baths, food, drink, poisons, bleeding, etc. Blagden ascertained that the temperature of a healthy body remained the same in a room heated to the boiling point of water. Then John Hunter published, in the "Philosophic Transactions (1775–78), his thermometric experiments, which were begun in 1766. He showed that animals, to which he had applied a thermometer so small that it could be introduced into the urethra, could bear the external cold because they produced heat enough within themselves to counterbalance it. The proposition that in fever the temperature of the body increased about 12 degrees F., led him to investigate as to whether the increased heat could also have its origin locally in parts of the body. Thus he was the first who marked the rising of temperature in inflammation. After the operation for hydrocele he found the temperature of the tunica vaginalis 33.3 degrees Cels. (Hunter measured according to Fahrenheit.) The cavity was filled with lint, which was covered with salve, and on the following day, when inflammation had developed, the thermometer showed 37.08 degrees Cels., a considerable rise. But this is apparently not the case of the temperature of the blood, for he considered that the blood in a healthy condition had a maximum heat and thought that nothing, not even local inflammation, could raise its temperature beyond this degree, excepting a general affection. Although the inflamed parts of the body have a higher temperature than in the normal condition, yet the differences are too small to account for the febrile rise of temperature of the whole mass of blood. Natural heat, he thought, did not arise from the movement of the blood, but he considered it very probable that it depended upon a principle which was intimately connected with life and independent of circulation, sensation and will, and that the chief source of animal heat lay apparently in the stomach. Hunter considered the determination of the degree of temperature of a patient by feeling as inadmissible in the extreme, because the personal temperature of the physician never stood at a fixed point. Through measurement one comes nearer to the truth than is absolutely necessary for pathology. Soon afterward there appeared in France the celebrated work "sur la chaleur" in the Mém. de l'acad. 1780, by Lavoisier, the discoverer of oxygen. He thought, with Laplace, that the cause of natural heat lay in the chemic combination of oxygen with hydrogen and carbonic acid in breathing, and placed the seat of the formation of heat in the lungs. The English military surgeon, Hamilton, declared in 1789 that a good, accurate thermometer for determining heat in fevers was very necessary to surgeons. In 1797 James Currie published his valuable "Medical reports on the effects of water, cold and warm, as a remedy in fever and other diseases," in which, for the first time since de Haën, measurements of temperature, which always were appended to histories of cases, were again made valuable for purposes of therapeutics. This method pervaded Currie's entire practice. In the variations of natural heat he examined the effects of cold and warm water, of digitalis, of opium, etc. In spite of many editions and translations his work had no real influence on his contemporaries; the practitioners of all countries did not in the least consider the heat of the patient. In 1821 Hufeland drew Currie's work from oblivion for a short time when he issued a prize essay on the examination of these experiments. (Wunderlich.)

The preponderatingly practical direction which de Haën had taken was followed after his death by his Vienna colleagues. They did not concern themselves with theoretic researches and were indifferent to all new ideas. Störck and Stoll exerted the most influence, the former principally in Austria, the latter in all Germany. *Störck* (1749–1803) became chief of the department of medical instruction in Austria, after van Swieten's death, in which position he issued a far-reaching regulation that students and teachers must be brought under discipline. They prescribed the books which must be taught and studied and introduced the censorship. These chains placed upon Austrian medicine necessarily made a free development impossible, and the immediate consequence was that, in spite of the enormous mass of material for observation, which was created by the founding of the general hospital, the Vienna school fell into decay. Störck made many pharmacologic investigations, especially concerning hemlock, which he recommended for scirrhous indurations and malignant ulcers, and on stramonium, hyoscyamus, aconite, colchicum, etc. His colleague, *Stoll*, educated by the Jesuits, entered their order and afterward withdrew from it. He had studied medicine under de Haën. Through his marrirge he received the clinical professorship in Vienna, and soon his lectures became world renowned, so that pupils flocked to him from all sides. Nevertheless, he had to suffer neglect, in that not he but his personal opponent, Quarin, was appointed director of the newly founded hospital of Vienna and they placed only twelve beds at his disposal. Careful observations and accurate dissections distinguished him. His most important idea was that retained gall is frequently the cause of acidity, and the most varied diseases are generated by the introduction of gall into the blood. Thus ophthalmia arises if gall is lodged in the eye. Apoplexy, if it flows to the head; similarly, angina, cholera, pneumonia, petechiæ, asthma, etc. In dissections he very frequently observed a bilious pleurisy and considered a bilious character very prevalent in epidemic fevers. In consequence of this opinion, emetics which would remove the gall were the principal remedies and there was a time in Germany when, through the general acceptance of Stoll's doctrine, purgatives and emetics were universally used. When later this system of therapeutics did not fulfil his expectations he asserted that this came about from a kind of epidemic, changing at certain times, which, from 1776 to 1780, in Vienna had become thoroughly bilious and inflammatory, and added somewhat of pleurisy to all diseases. In regard to the emetic of de Haën, both he and his colleague, Störck, changed their views and both also desisted from frequent bleedings, which de Haën had recommended.

We stand in the midst of the second half of the century, where, in the continual strife between the two systems of Hoffmann and Stahl and the doctrines of Haller, the chief principle of these theories was lost. Hoffmann's nerve fluid was not generally satisfactory, since it was not to be demonstrated, and instead of this theory, brain and nerves were thought to be the only organs which exercised control over the whole body. From them all diseases were said to spring, through them all medicines to work. Hence arose the nerve pathology, which was introduced into Germany by *Unzer* (1771). He already knew the distinction of transmission from the brain to the separate parts and conversely from the periphery to the brain through different nerve fibers. As a system, the nerve pathology of the Englishman Cullen became incorporated into medical practice. As the nerve fluid failed, so the soul; it was no longer thought to be a part of the organism, although they admitted a psychic influence upon the operations of the body. Now, in order to understand the connection between the soul and the body, a middle term was necessary and, as such, fancy created a life principle, a power different from the soul, which without any clear conception was called vital force (Lebenskraft). To this confusion was added Haller's theory of irritability, distorted in every direction.

While the theorists turned their attention almost entirely to the solid parts of the body, although less in their anatomic bearing than as regards irritability and sensibility, the practitioners chiefly took up the fluids and acidity. Thus the gulf between the pathology of the solids and the pathology of the fluids grew wider. As an adherent of the latter, *Christian L. Hofmann*, who derived all diseases from an acid or putrid condition of the fluids of the body, acquired great influence, as also did *Kämpf* of Zweybrücken, through his work on constipation. Besides Stahl's fundamental ideas on the obstruction of the portal vein he considered coagulation, *i. e.*, the thickening of the fluids in the intestines and vessels of the abdomen as the most prolific source of many abdominal affections; for this he devised his visceral clyster, which has become celebrated (1784). At the same time attempts were made to classify diseases according to the ideas of the botanists. Sauvages of Montpellier made the first move in this direction, and in his system, in which diseases were classified according to symptoms, there were contained 295 genera morborum with about 2,400 species, which were still further divided into classes and orders. Linnæus' celebrated name gave to this movement a higher significance, as Buffon's did to geology and Werner's to mineralogy, insomuch that it became very popular with physicians, and soon new and ill-fated classifications were daily put forward from all sides.

In the contradictory waves of abstract definitions and empty works, in the constant theoretic discussions of the highest questions of life, which were indeed conducted with eminent ability and intellectual penetration in the eighteenth century, there was attained at least one advantage; the mind was exercised in free thought. In contrast with the intellectual torpor of the past this was certainly to be viewed as a step in advance. But one melancholy result was that many inferior minds produced an enormous and unfruitful literature. There developed a general confusion in the thought and language of German physicians continuing through two generations; not only this but all faculty for simple observation was lost. This lethargy might have been dispelled by a study of the ancients, but the men who were identified with the movement in the course of the century (Hebenstreit in Leipzig, G. G. Richter in Göttingen, Triller in Wittenberg, and later Gruner, Baldinger and others) displayed nothing but medical pedantry, which they paraded in their writings.

No time could be more fitting for a revolution than this, when every higher impulse and all fresh vitality was lacking in medicine. Accordingly the system of *John Brown* at the end of the century passed through Germany like a flash of lightning. From a poor but gifted Scottish family, he was at first a linen weaver and afterward became a tutor. Brown had given up theology on translating a medical dissertation into Latin for an acquaintance. He now devoted himself to the study of medicine and, unfortunately, also to brandy, to which he adhered during his whole life. His unbridled excess undermined his health and led him to bankruptcy. Then Cullen took an interest in him and made him a "privatissima" instructor for his students. But the love which Brown at first cherished for his teacher was soon changed to hatred when a professorship was denied him. In opposing Cullen he published a new system ("Elementa Medicinae," 1780) and thereby fomented a strife in the Edinburgh Faculty. They attacked and persecuted him in every way they could; and on the other hand he in his lectures did not scruple to heap gross abuse and detraction upon the hitherto prevailing system of medicine. The students divided themselves into two parties and seem to have taken up the quarrel of their teachers with their fists. Brown, on account of his extravagance, was again thrown into the debtor's prison but was liberated through money furnished by his students. He went to London, but his success there was only slight in spite of the fact that he sought to attract students to himself by means of a Free Mason's lodge. A call to Berlin was frustrated by his sudden death (1788); being drunk, as usual, he took an overdose of opium and died of apoplexy. He regarded the source of life as consisting in excitability, *i. e.*, the capacity which exists in every part of the body, and through which an external stimulus is able to excite a certain activity. He admitted that he did not know what this excitability is, but he assumed that it has its seat in the nerve medulla and the muscle substance. The effects of the stimulus to the sensibility he called *excitations*, and regarded life as a chain consisting of these effects. He considered that health rests on a moderate excitation and diseases arise when the stimulus is too high or too weak; in the former case there results a sthenic condition and in the latter case an asthenic condition. The difference between health and disease consists simply in a different degree of excitation. "The simplicity to which the medical science is reduced is so great that a physician when he approaches the sick bed need only understand three things clearly: 1. Whether the disease is general or local. 2. If general, whether it is sthenic or asthenic. 3. Of what degree the ailment is." These are Brown's indications in the therapeutics of general diseases. He did not concern himself with the seat and the course of them. In sthenic diseases the excitation was diminished by means of the weakening *remedy antiphlogose: in asthenic cases, and these were* not frequent, it was increased by the use of stimulating remedies, spirits and especially opium. Brown himself had fully experienced the stimulating effect of opium, for before and during his lectures, in order to stimulate his mind he repeatedly drank a glass of brandy containing fifty drops of laudanum. "Opium mehercle non sedat" was his motto. What a vicious influence his excesses had on his therapeutics was shown among other things, in his treatment of typhoid, in which he administered from ten to twelve drops of laudanum every quarter hour, gradually increasing the dose. By the end of the century opium had become almost a household remedy among the English and was misused to an almost incredible extent. In Germany some favorite syrup was added to every compound, while in England such and such an amount of tinct. thebaica was admixed.

While the English with their tendency to empiricism remained rather indifferent to the system of their countryman, it found an enthusiastic reception in Germany on the part of the rank and file of unripe academic teachers and thoughtless practitioners. It was dazzling in its simplicity; there was no system by which diagnoses could be so easily made and indications so readily determined. It was responsible for a scandal when Girtanner in 1790 published the Brown system in a French journal as his own. The strife soon waxed violent and painful, and the system was proclaimed in Germany with unheard of arrogance. All the journals swarmed with articles for and against it; indeed, German medical literature for a few years consisted of nothing but stimulus and excitation and direct and indirect infirmity. Hufeland early asserted himself against the system, although he recognized Brown's mental penetration and sought to discover a few useful doctrines in the mass of false propositions. The most enthusiastic adherent was Röschlaub, who indeed founded his own magazine as an organ of the excitation theory, and therein his polemics soon degenerated into common ridicule. His fanaticism went so far that he, a German professor, did not scruple for the sake of the system to fabricate entirely and to publish the history of a case involving A. von Kotzebue, whom he believed to be in Siberia. The latter exposed the whole fraud, whereupon Röschlaub confessed the lie. They raged and quarreled on both sides. Those German physicians who were at the same time good surgeons, opposed the system. J. P. Frank, at first a moderate advocate of the Briton, afterward withdrew; and when Stieglitz, with his sharp critique, had given the system a telling blow, the excitation theory waned. It was Schelling's natural philosophy that at the beginning of this century ushered in a new epoch. The history of Brownism strikingly illustrates the transient character of medical theories. Within the short space of ten years it had been promulgated with fire and sword, and in most of the universities was dispensed to the young physicians as the only saving doctrine, and was within that time borne to its grave.

At the turning point of the century a very marked step was accomplished in the application of chemistry and physics to the theory of medicine. After the discovery of oxygen, which brought about the fall of Stahl's hypothetic phlogiston, Girtanner asserted that oxygen was the life principle of all organic nature. Thereupon developed an antiphlogiston school, which in most diseases assumed the presence of too much oxygen, and in a few diseases too small a quantity of oxygen. Irritability and sensibility had previously been the battle-cry; now they dreamed of oxygen, hydrogen and carbon. In physics Galvani had made the discovery of animal electricity, and Volta had discovered the Voltaic pile. These things were eagerly seized upon and forcibly adapted to a theory of medicine. They considered electricity as the living force, believing irritability to be concentrated at the positive pole and sensibility at the negative, and other similar fancies; in short, the processes of life were regarded as an involved galvanic operation (Reil). A. von Humboldt was identified with this movement, and in 1797 published his experiments with vivified muscle and nerve filaments.

We will here close our review of the theoretic investigations in German medicine. In spite of the great partiality for this kind of work, yet special pathology was by no means neglected in the eighteenth century, and in Germany was represented by a small but eminent company of practicing physicians. These often instinctively hit upon the right method, applying themselves to the description of diseases, and in their therapeutics observing great simplicity and avoiding all extremes. Of course the details of pathology could be pointed out only in the most general outlines. Here above all shone the systematist, Friedrich Hoffmann, who first furnished an accurate description of chlorosis, diseases of the liver and esophagus, and first asserted that apoplexy consisted of the bleeding of a ruptured blood vessel of the brain. He also wrote good works on hysterics and scurvy. His colleague Stahl, treated the subject of hemorrhoids. The Vienna school followed an essentially practical tendency and employed itself especially with diseases of the respiratory organs. Here the most important discovery was that of percussion by Auenbrugger ("Inventum novum ope percussionis occultos pectoris morbos cognoscendi," Vindob. 1760), which however was not at all appreciated by his contemporaries. Van Swieten first asserted that epilepsy was a disease of the brain, and in the treatment of syphilis he introduced a solution of sublimate in brandy, and did some very careful work in tuberculosis of the lungs. Like Boerhaave he recommended in this affection thorough inhalations of steam from warm water and vinegar in order to induce expectoration. A. G. Richter was also convinced that the local treatment of the tuberculous sores in the lungs by means of inhalations was of the utmost importance, and that it was often neglected with disastrous results while everything was expected from the use of internal remedies. The Prussian regimental surgeon, Ollenroth (1798), after paracentesis of the breast used inhalations of warm steam from his inhalation machine and achieved the best success. Later Hufeland recommended for consumptives and asthmatics the construction of a pneumatic cabinet, *i. e.*, a room filled with carbonic acid gas in which the patients should inhale for the space of half an hour or an hour. The inhalation system was not neglected abroad, and in the seventies balsam steam was celebrated for tuberculosis. The Englishmen, Bennet and Mead, used *frankincense, storax and benzoin*; the Frenchman, Billard, used the steam of pitch, turpentine and Peruvian balsam.

At the end of the century there came into use inhalations of ether which Currie recommended in cases of asthma and Pinel in membranous croup. The English military surgeon Hamilton, for inflammation of the throat and tonsils, employed an inhalation apparatus which consisted of a funnel with a bent tube two feet long. The funnel fitted directly on the opening of a teakettle, in **which** warm steam had been generated by the boiling of herbs, and the patients inhaled through the small opening of the pipe (1789). Whooping cough, pleurisy, lead diseases, etc., were treated by de Haën; Plenk supplied the first classification of skin diseases (1776). Certain epidemics of the time gave a special character to practical medicine. In 1708 and 1709, in consequence of the war, the plague raged in Prussia, and in Danzig alone 24,500 men died; a few years afterward it spread to Austria, Bavaria and Holstein. Epidemic catarrh and exanthematic typhus appeared frequently, and abdominal typhus was first described in 1762 by Röderer and Wagler. Friedrich Hoffmann, van Swieten, de Haën, Werlhof supplied important contributions on intermittent fever, and gastric fever gave the Vienna physician, Stoll, occasion to develop his fundamental propositions on the bilious character of this disease. Poisoning by lead, and especially by ergot, was accurately observed and chronicled (Wichmann and Zimmermann). Trustworthy observations on scarlet fever were first made in the eighteenth century by the body physician Storch in Gotha (1742). Among the most important contagious diseases was smallpox, concerning which the principal point of interest lay in inoculation, by which its ravages might be checked. This was in general use in Constantinople in the eighteenth century among the Greeks. The wife of the English ambassador at the Turkish court, Lady Montague, had her child inoculated by her surgeon, Maitland, and after her return to England did everything in her power to introduce inoculation. Maitland, at the request of the Princess of Wales, inoculated six criminals in London, in August, 1721; since that time the new method has been transplanted to all civilized nations. In Germany, as it appears, J. E. Wreden, for the first time in Hanover, inoculated several children (Feb. 2, 1722). The second most important epoch begins with Jenner's introduction of vaccination, for which he deserves the greatest gratitude from mankind. The first vaccination in Germany was performed in Hanover in May, 1799, by Ballhorn, who had translated Jenner's first famous work ("Inquiry Into the Causes and Effects of the Variolæ Vaccinæ," 1798), and by Friedrich Stromeyer, with lymph sent them from London. From this point the introduction of vaccination spread to the whole kingdom. The two colleagues sent lymph to Vienna and other cities, and after about one year had accomplished, together with other Hanoverian physicians, over seven hundred vaccinations, probably the most extensive experiment which had been made in Germany up to that time.

With the perfecting of chemistry, materia medica took a new impetus. So long as the former remained in its infancy, the latter was not much more than a trade in spices. The plants were brought to the apothecaries by the herb-gatherers and were often mistaken by both. Now chemistry produced the most powerful medicines from all the riches of nature. Botanic gardens were cultivated. A. von Haller established the garden in Göttingen and in 1739 had the first plants sown. Greifswald obtained such a garden in 1763. Phosphorus was used as a medicine and hemlock was introduced chiefly through Störck's efforts. Various narcotics, belladonna,[1] hydrocyanic acid, digitalis, arsenic, quicksilver, bismuth preparations, lime water, etc., found many applications. Baths and springs came into use especially through Friedrich Hoffmann; and Driburg, Wildbad-Gastein, Nenndorf, Saidschütz, Seidlitz, Selters and others appear among the newly discovered springs. Even electricity was turned into a remedy and first used by Professor Kratzenstein in Copenhagen (1745). They treated long standing paralysis with it, but went to extremes, as with all new remedies. They recommended it for every possible ailment (toothache, amaurosis, deafness, intermittent fever and for the killing of tapeworms), so that a reaction necessarily followed and such men as Haller opposed it strenuously. The mysterious forces of the magnet attracted Mesmer in Vienna. He believed he had discovered a still more effective power in his own hands and called it animal magnetism. In 1774 he made it public and magnetized, at first with the magnet, later, in numberless cases, simply by contact. His labors found little recognition from the various academies in Germany and Paris; the latter declared, at the instance of the king of France, that magnetism could do nothing without the help of the imagination. On the contrary, physicians and laymen, especially in France, took up magnetism with great enthusiasm. It invaded all the periodicals and much nonsense was compiled.

Aside from the Vienna school the Hanoverian court physicians were especially conspicuous as practicing physicians. The oldest among them was *Werlhof* (1767), who attached his name to the morbus maculosus first desribed by him. *R. A. Vogel's* (†1774) chief service was the founding of the first and also one of the best medical journals in Germany; aside from this he did considerable work in chemistry and mineralogy. *Zimmermann* (†1795), at first a physician in Switzerland, was an advocate of Haller's theory of irritability, and later, a warm friend of Kämpf's ideas. He wrote on dysentery and became especially celebrated through his two-volume work, "Von der Erfahrung in der Arzneikunst" (1763-64), which is still read with the greatest interest. The sketches concerning experience, scholarship, the spirit of observation and genius reveal the fine mind, penetration, and the many-sided culture of the author. *Wichmann* (†1802) published chiefly "Ideen zur Diagnostik" (2 parts, 1794-97), in which he pointed out, with great fidelity, the failings of medicine and sought to remedy them through the perfection of diagnosis. He deserves the credit of being the first to trace with certainty (1786) the etiology of the itch to the itch-mite, of which Bonomo had furnished the first exact description (1786). He first showed that in order to perceive the mite the black speck must be extracted and the parasite placed upon a green cloth where its movements can be observed. It was a long time before this etiology was accepted without question; even in the year 1834 Blazius asserted that the mites were by no means always present and were less the cause than the product of the itch. *Lentin* (†1804) wrote various contributions and notes, chiefly on croup and raphania. Aside from these Hanoverians, *Johann Peter Frank* was conspicuous as one of the most celebrated practical writers of the eighteenth century (†1821). He was clinical professor in Göttingen and then in Pavia; in the latter place he organized the medical faculty and in 1795 became director of the general hospital in Vienna, where he founded the pathologic-anatomic museum. After a short stay in Wilna he went in 1805 to St. Petersburg as court physician. He had a clear and critical mind and did much toward introducing order nto special pathology and great simplicity into therapeutics. In his masterpiece, "System der Medicinschen Polizei" (6 Parts, 2d Ed., 1784-1819), he became the author of a new discipline and wrought incalculable benefit through his opposition to the monasteries and to celibacy, witchcraft and exorcism, and through his demands for freer education of youth. Among the eminent practitioners belong also the court physicians *Selle* of Berlin and *Samuel Gottlieb Vogel* of Rostock, who deserve credit for the general introduction of sea bathing and the opening of Doberan (1794).

---

[1] Just a hundred years have passed since the property of dilating the pupil of the eye was discovered in belladonna. When Darles ("de Atropa Belladonna," disp., Leipzig, 1776) got a drop of the fresh liquid in his eye and in consequence of this could not see well for three weeks, Dr. Reimarus found the pupil very much dilated. He thereupon decided to use this poison to paralyze the iris for extraction of cataract. Experiments on cats established the dilation of the pupil and in dissection the iris was found to be much relaxed and drawn back. Himly first applied this discovery to ophthalmology.

As we leave German medicine with the beginning of the nineteenth century, we must accord full recognition to the actual investigations of certain men, and also admit that the scientific status of medicine has been unquestionably advanced by the correction of conceptions and a more logical order. But alongside of the relatively small number of men of high merit who monopolized and dominated science, there went a great crowd of the crudest practitioners without knowledge and with a tendency to superstition, who showed the greatest partiality for speculations and catch-words, and on the other hand despised experiment and everything practical. Educated in the adherence to systems, they could contribute nothing to the advancement of medicine because they considered it scarcely capable of improvement. They treated the patient according to fixed rules and if he died they were content with the thought that they had done everything that was possible in their art. One single modest fact is worth more than ten hypotheses, but now they *subordinated experience to theories*, were conscienceless enough to fabricate accounts of cases and successful cures, and discarded the most decisive experiments as soon as they contradicted the prevailing opinion. This was carried so far that one otherwise worthy scholar contended against the truth, proved by a thousand years of experience, that cold locally applied would stop bleeding, because it did not accord with his system. Great thinkers were observed to give orders of which the most miserable field surgeon ought to have been ashamed. Few men could be convinced that all efforts to establish a durable system were in vain and that the path of experience trodden by Hippocrates and Sydenham could alone lead to the goal. Thus the faculty for observing nature was suppressed in most young physicians in their earliest education, and the most prolific source of all progress was cut off.

"If the sons of Æsculapius, they, to whom the muses were never very partial, have always made themselves contemptible by a fruitless conformity to the schools of philosophy of their time, yet one does not find this useless effort in the history of surgery. If the physicians have always sought to cover their want of clear insight with a foolish display of new and pompous, foreign and unintelligible words, yet simplicity and clearness, harmony and true worth made their appearance much earlier in the writings of the great surgeons." (Kurt Sprengel.)

SOCIETY PROCEEDINGS.

International Medical Congress.

Twelfth Triennial Meeting Held at Moscow, Russia, Aug. 17-20, 1897.

(*Concluded from page 698.*)

"The organic complexity of the cell is the simple and significant principle we bequeathe to the twentieth century," were the concluding words of Prof. S. M. Loukianow's address at the third general session of the Moscow Congress. The biologic autonomy of the cellular nucleus is especially evident in the phenomena of inanition. The cell becomes smaller in inanition, also the nucleus and the nucleolus, but the nucleus does not shrink in proportion to the body of the cell but independently of it, and the nucleolus independently of both. It becomes evident that the body, the nucleus and the nucleolus live a unified life but not one and the same life, a common but not an identical life. He measured 18,000 nuclei, each two diameters, taken from the hepatic cells of white mice (20), subjected to absolute fast or special diet. He found that the nuclei show less loss of volume on a diet of cooked bacon, namely, 6.45 per cent.; on a diet of albumin, 22.04 per cent.; of peptone, 26.48 per cent.; of sugar, 39.19 per cent., and in absolute inanition, 44.56 per cent. He concludes therefore that the hepatic cells are nourished especially at the expense of the fats and albuminoids, while carbohydrates play a secondary part. Thirty-five thousand hepatic cells examined to find the proportions of double nuclei, showed: with normal regimen, 10.49 per cent. binuclear cells; absolute inanition, 13.53 per cent.; sugar, 17.18 per cent.; bacon, 25.01 per cent.; peptone, 27.11 per cent.; albumin, 28.67 per cent. He believes that there is no direct connection between ample nourishment of the entire organism and the multiplication of the neuclei; also that in the nucleus the factors which assure the preservation of its volume in inanition do not fully coincide with the factors which most predispose it to division. He referred to the facts established by Mad. Downarowitsch in regard to the cells of the anterior cornua in complete inanition, when the body had lost 39.8 per cent. in weight, the nuclei had diminished in volume an average of 25.4 per cent. and the nucleoli 42.5 per cent.

PRESENT STATUS OF THE NEW TREATMENT OF POTT'S DISEASE, FORCIBLE REDUCTION WITH TRACTION.

The sensation caused by young Calot's success with his *brusque redressement* has obscured the merits of A. Chipault's less startling method, the first proposed. He straightens the curved spine by traction in narcosis and presented patients thus cured in October, 1895. He restricts the operation to easily reduced cases and aims to secure permanent correction by lacing the apophyses together with wire, including the sound vertebræ above and below (*vide* Journal, pages 505, 607). His success has been constant and permanent to date. Calot reported 204 patients operated (narcosis, traction and direct pressure on the hump) with two deaths within a few days and three in three to four months afterward. He now cures the abscess before operating and if necessary resects some of the posterior processes. Paralysis is an indication for operating, he states, adding that six were cured of the paralysis in these cases of the kind operated on. The result was null in the other two. Twenty of his patients are now walking straight, but most of them still wear the corset. He only allows them to walk when a radiograph shows the reparation of the osseous lesions. T. Jonescu described a mechanical contrivance for traction with which he regulates the force applied. He also replaces the cotton in the corset with a Sayre flannel vest. He has been successful with his modified Calot method, which is illustrated in his *Revista de Chir.*, Bucharest, No. 5. P. Redard reported thirty-two cases successfully treated with another traction device and lever apparatus, that reduces the curvature without direct pressure on the hump, afterward applying a very large plaster cast, illustrated in the *Presse Méd.* of September 4. Bilhaut suspends the child by the feet to apply the corset. Professor Lorenz found paraplegia follow his only attempt, still persisting two. months after the *redressement*, as he states in the *Deutsche Med. Woch.* of August 26. All are surprised at the facility with which the spine can be straightened, and many are attempting it, but the medical world at large is waiting to see if nature will repair the loss of substance sufficiently to maintain the spine permanently in the corrected position.

CHRONIC NEPHRITIS.

In the addresses and discussions of chronic nephritis it was stated nephritis is apparently becoming more frequent (Gerhardt) and is often overlooked. Arteriosclercsis produces renal troubles sometimes at a very early age. Primary contracted kidney is the effect of intoxication, alcohol, uric acid, etc. Scarlet fever and pregnancy only lead to it when there are concomitant causes. It has in turn a toxic effect, uremia. Pressure can not be the cause, as he practiced lumbar puncture once without results. Ewald called attention to the cyclic appearance of albumin in the urine of children otherwise apparently in perfect health, with the exception of slight evidences of dyspepsia. He has had no opportunity to observe whether nephritis follows later. Brault signaled the hypertrophy of the heart which accompanies every nephritis of any duration and dominates the entire pathology of nephritis. It is irreparable and the kidneys only act as long as there is certain compensation of the heart. Crocq considers the desquamation of the epithelial elements the indispensable starting point for the albuminuria. Consequently there can not be physiologic albuminuria, but the cause producing it may be transitory; it may, for instance, be merely hyperemia, active or passive, such as renal congestion from cardiac valvular insufficiency. But generally the cause of the albuminuria is a parenchymatous renal inflammation. Interstitial nephritis is quite different; this is inflammation of the connective tissue of the kidneys. If the epithelium is not involved there is no albuminuria until it is. In the clinical sense, therefore, there are two kinds of nephritis, with and without albuminuria, and these correspond to the anatomic forms, parenchymatous and interstitial. Different causes may produce one or the other; cantharidin, for instance, produces parenchymatous inflammation, also beer; while distilled beverages, lead and uric acid induce the interstitial form. Senator ascribes to arteriosclerosis the origin of many cases of chronic nephritis, and senile chronic cases to insufficient irrigation of the kidneys.

TETANUS IN CHILDREN.

Escherich stated the invariable coincidence in his experience of slight rachitic alterations with idiopathic tetanus, also its restriction to the spring months, and the age from three months to the end of the third year. He does not consider them related, but ascribes both to intoxication from vitiated room air. Some of the fatal cases had hydrocephalus. Laryngospasmus may therefore be a symptom of fresh hydrocephalus, as Golis maintains. In other cases there was thymus hyperplasia, bronchitis or lobular pneumonia, and three had edema of the glottis.

An effective test of the efficacy of serum treatment of diphtheria was reported by Fibiger, who stated that the one thousand patients admitted for diphtheria at the Copenhagen Hospital during the year were treated with serum or not according as they were received on alternate days and nights. Five hundred had the true Löffler bacillus. The value of the treatment was unquestionable.

A. Esquerdo advocated bandages for fractures of the inferior member (made of plaster, flannel, cotton or mull, with the first the preference), allowing the patient to walk from the first.

Bertran of Barcelona attributes the soothing effect of the heteronymous application of the hand of the operator in certain neuralgias, etc., to the "odic effluvia."

America was well represented, with numerous important addresses and communications, some of which have already appeared in these columns.

The medico-legal significance of the glycogenic function of the liver is much greater than usually realized, as the presence of glycogen in the liver after death shows that the fetus or individual was in normal health at the moment of death, which must have been due to traumatism of some kind. The absence of glycogen is an evidence of diseased conditions. Lacassagne and Martin base this assertion on an examination of 200 subjects, the only qualification to the statement being in case of death from mechanical obstruction in the course of some disease, like tuberculosis. They used Claude Bernard's test, and did not include diabetics in their research, as this test is not reliable with them.

J. F. Sutherland remarked *in regard to the alcoholic before the law*, that punishment for a crime committed during drunkenness is, in this nineteenth century, a monstrosity. The punishment should be for the drunkenness, which should be considered a misdemeanor. The alcoholic should be regarded by the law in the same light as an insane person. He should be deprived of his civil rights and incarcerated until cured in some special institution.

W. A. Muratow announced as the result of the necropsy in 123 cases of progressive paralysis at Moscow: 1. Foci of infection in the form of hemorrhage or softening are rare (5 in 123). 2. The local symptoms that appear in the form of epileptic or apoplectic ictus are not due to any new complication, but merely to the invasion of the central convolutions by the inflammation. 3. Clonic convulsions should be considered compulsory movements of ordinary cortical origin. 4. Likewise, the disturbances in the muscle sense and hemianesthesia. 5. The pathogenesis of the appearance of the foci has a certain analogy with the focus infections in encephalus, due in both cases to the direct or indirect action of the focus (excitation, degeneration).

Sir Dyce Duckworth reported several cases of abscesses of the cerebum or cerebellum consecutive to otitis of the middle ear, in which the patient ceased absolutely to breathe from three to five hours before the heart stopped beating. This phenomenon has been previously observed in cerebral injuries from gunshot wounds.

Linnggren reported that he had succeeded in transplanting pieces of epidermis on fresh and granulous wounds, which adhered and grew as desired in nearly every case, although they had been kept in sterile liquid-serum from a day to six months.

The parasite of malaria was declared single and unique by Coronado of Cuba, but Thayer of Baltimore, Saharow of Tiflis and Gautier of Moscow asserted the existence of three varieties.

SELECTIONS.

Congenital Absence of Uterus and Vagina.—Plastic Operation for Artificial Vagina, Taking Flaps from Nymphæ and Perineum.—M. A., aged 19 years and single, a native of Gloucester, Mass., was sent to me by Dr. G. N. Jones of that city and gave the following history:

Her father was born in Sweden, her mother in Nova Scotia, the latter having died of cancer of the uterus six years before. With this exception the family history was negative. Of her three sisters, one was married and had a child; another, 16 years old, had menstruated regularly for four years, and the third, then 14 years old, had not at that time had her catamenia established, but since has menstruated regularly.

The patient had never been in rugged health, had suffered with a purulent discharge from the left ear since 1 year of age, and had had measles and chickenpox at 7 to 8 years of age. She had been under medical treatment for the preceding four years for general weakness, headache, weak eyes (for which she had been wearing glasses with benefit), temporal headaches, sore throat, loss of appetite and shortness of breath. While under treatment she had improved; at the time of my first consultation had a fair appetite and digestion, and her chief complaints were a weak back and the fact that she did not menstruate. There had been no menstrual molimen whatever.

Physical examination showed a well developed, rather poorly nourished woman above the average in height, of light complexion, the hair of the head long and thick, voice feminine, breasts each having a well-developed gland with a few follicles showing in the areolæ about the inverted nipples, hips large and pelvis of female type.

Genital organs.—An abundant growth of hair on the mons and the outer surface of the labia majora. Labia majora, labia minora, vestibule and clitoris well developed; meatus urinarius and urethra of large caliber, taking a sound fourteen *millimeters in diameter without much stretching*; natural diameter about eleven millimeters. Hymen absent. Where the introitus vaginæ is normally situated the mucous membrane was redundant and wrinkled, and in the center was the opening of a small pocket four millimeters in diameter. This pocket had a depth of one and one-half centimeters, its long axis corresponding with the axis of the normal vagina, and it was apparently lined with mucous membrane. A small amount of milky white secretion could be expressed from it. Orifices of vulvovaginal glands large and normally placed. In other words, with the single exception *that the introitus* vaginæ and hymen were absent, the external genitals were normal.

As a bimanual examination with a finger in the rectum failed to reveal the presence of the uterus or other internal organs of generation the patient was sent to St. Elizabeth's Hospital, where an ether examination was made on the following day. Two of my colleagues on the gynecologic staff of the hospital kindly saw the case with me. We all examined bimanually with the forefinger in the rectum, also with the little finger in the bladder; then with a sound in the bladder and a hand on the abdomen. The abdominal walls where thin and lax, the intestines undistended and, the rectum and bladder being empty, all the conditions for practicing the touch were favorable. No uterus, ovaries or tubes or any thickened tissues that might represent any of those organs, or the occluded vagina, were to be felt in the pelvis. The bladder and rectum seemed to be of normal size, shape and situation. The septum between the bladder and rectum was thin.

The condition of her genital organs were explained to her and she was told that possibly a serviceable vagina could be made and decided to have the operation performed.

Operation, March 28, 1894.—The object of the operation was to separate the bladder from the rectum by incising the cellular tissue between these organs and then to cover the raw surfaces forming the walls of the cavity so made with mucous membrane or skin, utilizing three flaps; one taken from the fourchette and perineum and one from each of the labia minora. The vulvar hair was shaved and the rectum thoroughly irrigated with corrosive, and the orifice of the rudimentary vagina prolonged at each end so that it measured about three centimeters in length, splitting the rudimentary vagina into halves. With a finger in the rectum and a sound in the urethra for guides, the recto urethral septum was split by dissecting with the scissors and finger for a distance of five centimeters. At that point the finger in the wound was apparently separated from the intestines by a sheet of peritoneum only and, practicing the bimanual touch again, it was impossible to discover the presence of any tissue that might represent the uterus, ovaries or tubes.

In order to cover the raw surfaces formed by the dissection, flaps were formed as follows: the nymphæ were cut off and then incisions through the mucous membrane made. The two lateral flaps formed in this way were dissected free and by so doing the nymphæ were split from their posterior aspect and unfolded, as it were.

The posterior flap was formed by dissecting deeply the tissues of the fourchette and perineum, so that this flap could be dragged upward and inward to cover the posterior surface of the new vagina. The strip of mucous membrane on this posterior wall that had been half of the rudimentary vagina was dissected away and the posterior flap anchored by suturing its tip at the uppermost part of the new vagina with a catgut stitch. In the same manner the two lateral flaps were disposed of by stitching their tips at the apex of the vagina. The little strip of mucous membrane on the anterior wall from the rudimentary vagina was utilized by stitching the lateral flaps to its edges. The operation was completed by sewing the edges of the mucous membrane at the stumps of the nymphæ and at the places where the three flaps came into apposition with fine interrupted sutures of catgut. At the close of the operation there was a small raw surface, about one centimeter in diameter, at the highest part of the wound, that it was impossible to cover. The vagina was packed lightly with iodoform gauze and the patient put to bed. The after-treatment consisted in keeping the vagina packed with iodoform gauze. The left flap broke loose on the third day, but by carefully applied pressure it glued on again. The house surgeon manufactured a dilator out of a rubber finger cot stuffed with cotton. This was worn constantly, being kept in place by a T-bandage. On May 1 the vagina measured two and one half centimeters in diameter and four and one-half in depth. The patient left the hospital on May 2, was not seen again until two years later, when she appeared at my office with her husband. She reported that she had gained very much in health and had been perfectly well, with the exception of weakness of the back after exertion and of a recent attack of indigestion; that she had then been married two months and a half; that she had had sexual intercourse regularly since marriage and that the intercourse was attended by sexual feelings and gratification. Her husband also said that, for his part, coition had been entirely satisfactory.

She now called my attention to a bunch in the right side of her abdomen, which she had first noticed before the operation; but as it had never given her any discomfort she had not spoken of it. It had moved lower down in the abdomen since the operation and since her marriage had increased in size. Examination showed a tumor the size and shape of a large kidney situated in the false pelvis on the right side, the hilum being toward the vertebral column. Its upper border, with the patient on her back, was on a line drawn from the umbilicus to the right anterior superior spine of the ilium. It slipped from under the hand in the manner characteristic of movable kidney, its mobility being limited above just beyond the level of the umbilicus, on the left at the median line and below at Poupart's ligament. Pressure on the tumor caused "a sickening sensation." Palpation in the right flank failed to detect the presence of the kidney in its normal situation. The urine was normal. It had been increased in amount, of late, she said. There had been no pain or dragging sensation in the region of the tumor.

The tumor was surely not in its present situation at the time of the ether examination two years before or it would have been felt at once by the examining hand on the abdomen. Bimanual examination with a finger in the vagina and with a finger in the rectum showed that the tumor had no pelvic connections that could be felt and confirmed the previous diagnosis of absence of the uterus.

Following the foregoing report the author commented briefly on the various operations that have been performed for the formation of an artificial vagina. The first of these was done by Fletcher in 1831 and Amussat in 1832, for the purpose of allowing escape to the retained menses. These operations were but blunt dissections in the recto vesical system. In 1883, Credé formed a new vagina by using one large skin-flap from one of the labia majora, while Picqué took flaps from the anterior wall of the vestibule and from the perineum. Kustner, Mackenrodt, Schwartz and others modified these. Other cases of plastic operation for artificial vagina have been published by Rosciszewski in 1894, Fenger in 1886 and Roux in 1891.

The advantages of a plastic operation for artificial vagina over the plug operation are obvious both in cases of congenital and acquired absence of the vagina. Where the labia minora are of sufficient size they seem to me to offer the most available means of covering the walls of a new vagina, as entailing less mutilation than would be the case with flaps taken from the labia majora or vestibule, and I should agree with Fenger that a bilateral operation is preferable to a unilateral one.

Complete absence of the uterus has been demonstrated by anatomic proof only in cases of acephalic monsters or fetuses with spina bifida or other malformations incompatible with prolonged life. In all other cases a small bit of connective tissue, a knot of muscle or band of connective tissue, if nothing more, as representing rudiments of the uterus, has been shown to exist on the cadaver.

A small piece of muscle without the shape of a uterus, or a band of connective tissue across the pelvis, can not be called a uterus either in an anatomic or physiologic sense, and such a state of affairs is of interest only from the standpoint of embryology; therefore, we are justified in speaking of women possessing such rudimentary structures as cases of absence of the uterus. The case just reported is an example of a not very rare class, *i. e.*, normal feminine habitus, well-formed hips, breasts and external genitals, hair of the head long, normal pubic and axillary hair, and feminine voice, with absence of uterus and more or less atresia of the vagina. These individuals are usually healthy unless the ovaries are present and functionally active, in which case they suffer from menstrual pain, sometimes so severe as to necessitate oöphorectomy.

Without aiming at absolute completeness, owing to the inaccessibility of some of the sources of information, I have been able to collect the references to 360 cases of absence of the uterus reported by 239 authors from earliest times up to the present. Roughly we may say about 300 cases in the last century. Cases occur in the literature of all civilized countries. I have examined a majority of the 239 references, and have found among them the records of only thirty five autopsies where this condition was present. Of these, twenty-four were on the bodies of adults and two on girls 10 and 12 years old respectively, the rest being on monstrosities and fetuses with absence of other organs, making prolonged life impossible. In all of the autopsies on the bodies of adults and girls there were noted in every case rudimentary tissues representing the uterus, generally one or two little knobs of tissue the size of hazelnuts or a thin band between the bladder and rectum. The ovaries were found to be present in all the cases but six, and five of these were reported in general terms only. The tubes were present in all cases but six, though often without any canal. A very large proportion of the reports I have examned are of cases similar to mine, *i. e.*, adult women, feminine habitus, normal external genitals and breasts. A very few cases having abnormal external genitals and the male type of breast, with absence of pubic hair, are reported. The vagina was generally present as a short pouch, though often entirely wanting. Absence of the vagina alone, the uterus being present, is a much more common anomaly than absence of the uterus.

In a considerable number of cases of absent uterus and vagina the urethra has been found to be of large caliber and in several cases coitus has been practiced through it without the knowledge of the patient that anything was wrong in this respect. Most writers hold that the large caliber in these cases is due to attempts at coitus, but in view of the fact that there are on record many cases of absence of the vagina in unmarried women of good character where the urethra has been found large, *e. g.*, my case above reported, it seems that the explanation is to be sought rather in some developmental defect.

The anomaly of absence of the uterus is due to a lack of fusion and subsequent atrophy of the ducts of Müller, a process which ordinarily takes place at the end of the third month of fetal life. It is well established that these ducts, under normal conditions, fuse in their middle and lower course, the process proceeding from above downward to form the uterus and vagina, whereas above the separate non fused ducts form the Fallopian tubes. The external genitals, the lower part of the vagina, as well as the urethra and vesical trigone, on the other hand, are formed from the urogenital sinus and the genital tubercle, furrow and fold. A partial coalescence of the Müllerian ducts accounts for the reported cases of double vagina and double and bicorned uterus. The derivation of the hymen is still in dispute. It is known that the hymen develops late in fetal life, the nineteenth week, and there seems every reason to believe that it is formed from the same embryonic structure as the vestibular vagina, *i. e.*, the urogenital sinus. Therefore, we should not expect to determine whether it would be likely to be present in any given case of absence of the vagina. As a matter of fact, it is reported as present in a majority of cases, as is also some sort of a vaginal canal. This canal must be thought of as a persistent urogenital sinus rather than a Müllerian vagina, because in the process of development the Müllerian ducts coalesce from above downward. The urogenital sinus develops from below—the urethra and rectum being set off from the vagina—and it is not difficult to understand how, in one case, the lower vagina fails to develop, giving rise to hematocolpus if the uterus is function-lly active, or, in another case, the uterus and Müllerian vagina ng absent, that the urogenital sinus forms an urethra of rge caliber and a hymen.

It would seem as if inheritance had something to do with absence of the uterus. Squarey reported the cases of three sisters who had never menstruated, three of whose aunts were sterile. Phillips speaks of two sisters, both married, with congenital absence of the uterus. Nelson reported absence of the uterus in three of a family of five sisters. All three had sexual desires. Of the two sisters with uteri, one had a family of four children, the other was 17 and unmarried. Sexual appetite was present in most of the cases reported. Menstrual molimina sometimes and sometimes not, but generally present where the ovaries could be distinguished.

It is seldom that a proper diagnosis can be made without an anesthetic. The thinness and condition of laxity of the abdominal walls are important factors in determining the accuracy of the examination. In some of the reported cases the diagnosis was confirmed by operation, as in several where oöphorectomy was practiced for severe menstrual pains.—*An abstract of a paper by* Dr. W. L. Burrage *in American Journal of Medical Sciences.*

The Organization and Support of Public Medical Libraries.—Dr. George M. Gould recently read before the American Association of Medicine of Philadelphia the following:

Every year many private medical libraries, innumerable medical books and journals, the gatherings of physicians during a lifetime, are destroyed, scattered and wasted. At the same time thousands of cities and villages are without public medical libraries, or the few that exist are not made the depositories of these valuable books. In the city and village centers the physicians are individually and singly spending large sums of money for medical literature, and much of this money, if spent in a systematic and organized manner, could be saved, would accomplish more good for the participating individuals, and would become a growing power for professional progress and benefit.

All that is wanting is the unitizing spirit to bring about common action. No argument is needed to convince us of the great value of a reference-library of medical books. Why then should this literature and money be longer wasted? Every member of the Academy should constitute himself a committee of one to arouse public spirit, to encourage the formation and support of public or society medical libraries. It is, indeed, a function peculiarly appropriate for the Academy as a whole to undertake. Moreover, every established medical library is constantly receiving, and with increased vigor would receive still larger numbers of duplicates, which by an easily devised system of exchanges and gifts, might be utilized to complete the files and fill the shelves of other libraries. To illustrate the effectiveness and success possible in the direction suggested, I may refer to an attempt I have made. With true professional spirit the editor of the Journal of the American Medical Association courteously placed his columns at my disposal, and I published therein lists of duplicates, gifts, exchanges, etc., of books and periodicals that were sent me by individuals and by librarians. Within the past year, as a result, I have been able to help a number of libraries to fill their shelves. With some good will and a very small expense for postage and typewriting, 3,934 journals and pamphlets, and 1,921 bound volumes, most of them of great value, have been rescued, preserved, and for all time, placed at professional disposal. It is, however, a work requiring more than individual effort, and should become the function of some corporate organization. The unexpected success of my individual labor only shows what wonderful results might follow common professional action. If anything good were to be hoped from American politics, the existing organization of the Surgeon-General's Office might be made a sort of clearing-house for gathering medical literature, and for founding and filling public medical libraries all over the United States. In pure science the Smithsonian Institution already exercises some such function, and it is one of inestimable value to the nation and to science. In other countries the medical literature we sadly need is to be had almost or entirely for the asking, just as with us it is also going to waste. To make the plan effective international organization is needed, and can hardly be brought about except by governmental agencies. Scarcely a complete set of the French *Theses* exists in this country, and yet I have seen such sets offered for sale for a few dollars. Two or three years ago, at a well advertised public auction-sale in the city of Philadelphia, I bought a complete set of Virchow's *Archiv* for $3.50. Another set was advertised by a Boston dealer the same week as a remarkable bargain for $185. Publishers' remainders of old editions are constantly being ground up into paper pulp, and the *Transactions* of hundreds of medical societies are rotting in store-rooms and cellars in Europe and America, while all the time the public medical libraries of each country are suffering because they can not secure the unutilized literature of the other. I allude to these instances merely in proof of the fact that from lack of organization we are neglecting unique opportunities of professional education and progress.—*Bulletin American Academy of Medicine.*

Toxin and Antitoxin of Tetanus of the New York City Health Department Laboratory.—Dr. Alexander Lambert, a bacteriologist having a special detail in the direction of the immunization against tetanus, has written for the *New York Medical Journal* June 5, the fullest American account of this procedure that we have yet seen. His article closes with a bibliography that includes no less than eighty-one titles, a large proportion of which is in the German and French tongues. Dr. Lambert has collected 114 cases, whose mortality under antitoxin has been 10.3 per cent. The tetanus antitoxin is prepared in the same manner as the diphtheria antitoxin, by inoculating the tetanus toxin in increasing doses into horses. The toxin is grown in bouillon under hydrogen, and after ten or fifteen days filtered through porcelain, and the germ free filtrate is used for the inoculations. The horses receive half a cubic centimeter as the initial dose of toxin, and this dose is increased as rapidly as the horses can stand it until they support seven to eight hundred cubic centimeters or more at a single dose. After some months of this treatment the blood of the horse contains the antitoxin in sufficient amount for therapeutic use. When the animals' temperatures are normal and they have recovered from the dose of toxin last given, they are bled into sterile flasks and the serum collected. The serum contains the antitoxin and is tested on white mice or guinea pigs.

The New York Health Department has at present two horses well immunized against tetanus, and furnishes serum of the strength of one to four hundred million, that is, one cubic centimeter will protect four hundred million grams of white mice against a three-to-four-day fatal dose of tetanus toxin. Reckoning in antitoxic units, twenty cubic centimeters of serum will contain eight thousand antitoxin units, an antitoxin unit in tetanus being the amount of serum necessary to protect one million grams of test animal. The serum is supplied in 20 cubic centimeter bottles and should be injected in 10 to 20 cubic centimeter doses. In severe cases the patient should receive 50 cubic centimeters in the first twenty-four or thirty-six hours, and these 10 to 20 cubic centimeter doses repeated once or twice each day during the following four or five days or longer, according to the course of the disease. The circular accompanying the bottles explains more fully the proper method of procedure.

As has been shown by Roux and Calmette, the antitoxic serum has no direct destructive action on the toxin itself, but through some unknown action on the body cells the serum prevents the toxin from exerting its destructive action. Behring's first idea that there was a direct destructive action between the antitoxin and toxin or some neutralizing effect, such as occurs between an acid and an alkali, has been shown to be incorrect. As Buchner also shows there is no destructive action of the antitoxic serum on the toxin either outside or within the body, the action seeming to be one which, by producing certain changes within the cells, renders the action of the toxin inert. Tizzoni concludes that the blood serum of inoculated animals does not act as a remedy which neutralizes in the organism a certain active principle of disease and directly counteracts certain functional changes, but it acts, in all probability, in curing tetanus by immunizing the parts of the body not already tetanized and so limits the tetanus to local form. The New York Board of Health supplies its antitoxin to charitable institutions free of charge, but to others the cost is $3.00 per vial containing 20 cubic centimeters. The serum should be injected as early as possible, as the dose required to neutralize tetanus toxin absorbed increases with great rapidity with each hour's delay.

The initial dose in every case in an adult should be at least one vial or 20 c.c. When the treatment is begun at the first appearance of tetanic symptoms and these do not point to a very severe infection, and especially when the incubation period has been long, say two weeks, the same quantity or one-half the quantity, according to the results, should be repeated at intervals of form six to twelve hours during the four following days.

London Experience in the Antitoxin Treatment of Diphtheria.—The report of the medical superintendents upon the use of antitoxin in the treatment of diphtheria in the Hospitals of the Metropolitan Asylums Board during the year 1896, which has just been issued, constitutes the most exhaustive and elaborate statistic study of the antitoxin treatment of diphtheria which has yet appeared.

The medical superintendents thus sum up the results of their clinic and statistic observations. They find that the improved results in the diphtheria cases treated during the year 1896 are: 1, a great reduction in the mortality of cases brought under treatment on the first three days of illness; 2, the lowering of the combined general mortality to a point below that of any former year; 3, the still more remarkable reduction in the mortality of the laryngeal cases; 4, the uniform improvement in the results of tracheotomy at each separate hospital; 5, the beneficial effect produced on the clinical course of the disease. "We have had, in fact, somewhat better results to record for 1896 than we had for 1895; and in view of the extended experience gained during the past year, together with the additional facts concerning the post-scarlatinal cases for 1896, we feel that we are fully justified in the favorable opinion we expressed last year on the value of antitoxin in the treatment of diphtheria."

The reporters further emphasize the importance of early administration and the trivial character of the secondary effects, maintaining their opinion that "in the antitoxic serum we possess a remedy of distinctly, we would now say, much greater value in the treatment of diphtheria than any other with which we are acquainted."—*The London Therapist.*

Purulent Contamination of Milk.—Dr. W. R. Stokes, bacteriologist of the health department of Baltimore, and Dr. A. Wegefurth of the same city, call attention to the use of the microscope for detecting the contamination of milk by pus. The presence of this objectionable product indicates an inflammatory disease of the udder of the cow supplying the milk, a condition sometimes spoken of as "garget." The writers believe that they can trace to this condition a series of cases of mild gastro-intestinal irritation. Inflammation of the udder is a not infrequent condition among dairies that supply milk to our cities and institutions. The milk yielded by such diseased cows has often been found to contain many pus cells and the allied organisms of suppuration. The study of the epidemic of gastro intestinal disease of these writers and of other testimony in the same line, lead us to the belief that garget milk is a source of danger to infants and children. Whenever suspicious circumstances lead to the use of the microscope and an examination is made of the centrifugalized sediment of the milk that reveals the presence of an excessive amount of pus, there should be instituted a careful examination of the herd whence the milk has been obtained. The chances of infection by the milk of a herd can be minimized by a microscopic examination of the centrifugalized specimens of each cow's milk and the exclusion of any and all cows that are found to have pus-producing udders. The writers suggest that, in the absence of a better guide, the exclusion of a cow be based upon the presence of an average of more than five pus cells to the field of a twelfth-inch oil immersion lens. The writers point to the high mortality in their city by cholera infantum, a disease that is especially prevalent among children that are fed upon cows' milk, and their experience points to the necessity of a closer examination of the herds of dairies that send their product to our cities, if we are to expect a reduction in the summer mortality by intestinal derangements. It is not their contention that untested milk is of necessity dangerous, but the use of the test is prompted by the almost universal desire that exists to raise the standard of that important food substance of the young, especially in the summer season.—*Medical News.*

NEW INSTRUMENTS.

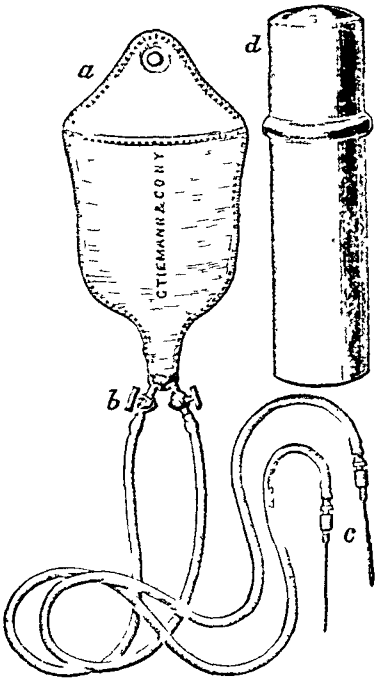
A SUBCUTANEOUS SALINE SYPHON SYRINGE.

BY HORACE FOX, M.D.

BATH, MAINE.

This simple instrument is brought to the notice of the profession for the following reasons, to-wit: It is compact, therefore it can be readily carried in an ordinary physician's bag and constitute a part of the physician's armamentarium. It is simple in construction, therefore there is practically nothing to hinder it from being in good working order at any and all times. Its parts can be quickly, thoroughly and easily adjusted, therefore it can be made ready for use at a moment's notice. When its parts are properly adjusted it is impervious to air. It can be made thoroughly aseptic by boiling or immersing in an antiseptic solution without injury to any of its component parts. The fluid can be injected simultaneously into different portions of the body with great ease. One quart of the normal saline solution can be subcutaneously injected in about fifteen minutes, provided its distribution and absorption is assisted by constant and gentle manipulations. The pressure and flow of the fluid can be controlled either by the stop-cocks or by raising the reservoir to the desired height, or by both.

To describe the instrument: The reservoir (*a*) is made of soft catheter rubber and will hold just one pint. Its upper portion contains a small perforated flap by which the instrument may be suspended. Into the lower portion of the reservoir is snugly fitted a hard-rubber tube (*b*) which is forked at its lower end and each prong of the fork contains a stop cock. Upon each prong of the fork is adj [illegible] cat [illegible] ubber tube three feet long. There are [illegible] the upper of which are fitted into the lower ends of the soft catheter rubber tubes, while the lower ends of the metal fittings are threaded and upon which are screwed two large size hypodermic needles (*c*). The reservoir and hard-rubber fork, the soft catheter rubber tubes and metal fittings need not be separated unless so desired: they can then be rolled up and placed in the hard rubber case, while the hypodermic needles may be secured safe and firm by being screwed into two tubes in the top part of the box or case (*d*). The hard-rubber box is round and is about seven inches long and two inches in diameter, therefore it takes up but little space and yet permits of ample room for the instrument.



The instrument was made for me by Messrs. George Tiemann & Co., of New York City and they have carried out my plans accurately and thoroughly.

A NEW OBSTETRIC FORCEPS AND AN AXIS-TRACTION FORCEPS.

BY A. B. SPACH, A.M., M.D

CHICAGO.

In the Journal of December 1896, I published a description of a "New Obstetric Forceps." In response to numerous requests for a detailed account of the axis-traction features of my forceps and under this stimulus, I have added to and recast what has already been published, making the description entirely a new one. A glance at Fig. 1 reveals the forceps with two circles described around it, having a common center, which is at the lock. A sector of the larger circle is formed by the blades and an arc of the same circle. Another is formed, by the handles and an arc of the smaller circle, or an equal one by the blades and an arc of the same circle passing through the blades, where they are farthest apart. Thus, as the blades are separated, the distances between them are accurately read off on the handle of the lower blade, which is marked off in centimeters and inches. At a glance the obstetrician can measure the diameter of the child's head. The forceps serves here as an accurate cephalometer.

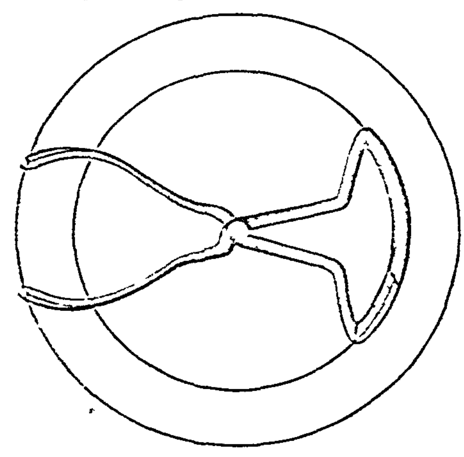


Figure 1.

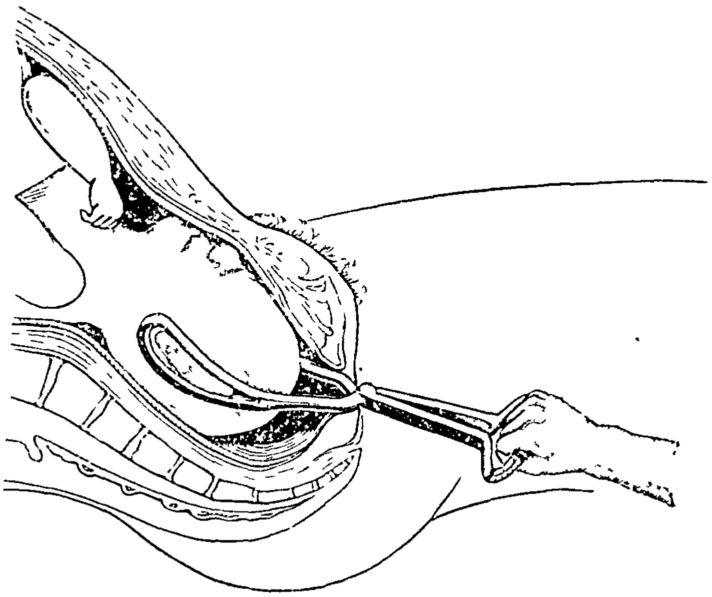

Figure 2.

Intermittent traction can be made without producing undue compression of the fetal head. Fig 2, represents the forceps applied in occipito-posterior positions, the grasp of the hand and the direction of traction after the head has made descent into the pelvis. In Fig. 3, is shown the axis-traction forceps with details of the lock of the axis-traction rods. These rods are applied after the forceps is adjusted to the fetal head. The blades are secured firmly by the clamp at E, on the handles. The traction rods, one at a time, are now attached to the blades at A. Further adjustments are made at C, and the handles at F. Motion is thus freely secured in all directions. After the head is drawn down into the pelvis, the curved rod is turned at right angles to the axis-traction rods and together with them quickly disengaged. The clamp at E is then removed and the labor is then completed as seen in Fig. 2.

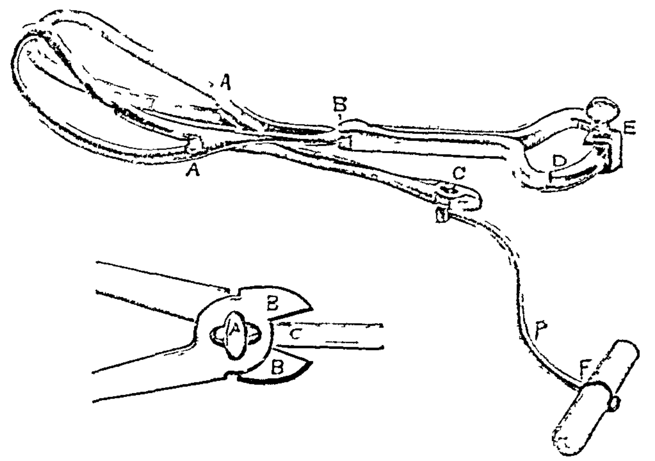

Figure 3.

To summarize: 1. The forceps accurately measures the fetal head. 2. Its application is no more difficult than any other instrument. The axis traction rods are applied more readily than in any other instrument. 3. And last, greatest of all, intermittent traction can be made without crushing the fetal head.

The lock and features of the blades are unique and new. This instrument is manufactured by Fred Haslam & Co., Brooklyn, N. Y.

6629 Harvard Avenue.

A BILL to Establish a Department of Public Health and to Define its Duties.

Be it Enacted by the Senate and House of Representatives of the United States of America in Congress assembled:

Section 1. That there shall be established a Department of Public Health, the duties of which shall be to collect and diffuse information upon matters affecting the public health, including statistics of sickness and mortality in the several States and Territories; the investigation by experimental and other methods of the causes and means of prevention of disease; the collection of information with regard to the prevalence of infectious, contagious and epidemic diseases both in this and other countries; also the causative and curative influences of climate upon the same; the publication of the information thus obtained in a weekly bulletin; the preparation of rules and regulations for securing the best sanitary condition of vessels from foreign ports, and for prevention of the introduction of infectious diseases into the United States, and their spread from one State into another, which rules, when approved by the President of the United States, shall, in so far as they are consistent with the existing laws, be adopted and enforced as quarantine regulations at the various ports of entry in the United States, and so far as applicable to interstate commerce to prevent the spread of disease from one State or Territory into another or the District of Columbia, be, and become additional regulations thereof; the advising and informing the several departments of the government on such questions as may be submitted by them to it, or whenever in the opinion of the Department such advice and information may tend to the preservation and improvement of the public health.

A special report of the said Department of Public Health, relative to such action as will most effectually protect and promote the health of the people of the United States may at any time be required by the President of the United States.

Sec. 2. That the Department of Public Health shall be under the control and management of a Commissioner of Public Health; said Commissioner of Public Health shall be appointed by the President of the United States, by and with the advice and consent of the Senate, and his term of office shall be six years; he shall be a regularly educated physician holding a diploma conferred upon him by a legally incorporated medical college in the United States; he shall have had at least ten years' experience in the practice of medicine, and shall be learned in sanitary science, and shall hold a membership in one or more reputable sanitary or medical associations in the United States.

He shall be entitled to a salary of $6,000 per annum, and his necessary traveling expenses.

That the Commissioner of Public Health shall semi-annually on the first Tuesdays of April and October of each and every year, and at such other times as he may designate, call to meet in the city of Washington, D. C., an advisory council to be composed of the secretary or executive officer of each State and Territorial board of health, and one officer learned in the law, detailed by the Attorney-General of the United States from the Department of Justice; and that the necessary traveling expenses of the said advisory council incident to their attendance on the meeting of the said council shall be paid on vouchers to be furnished by the Secretary of the Treasury, said meetings not to include more than six days at each session, unless a longer continuance shall be authorized by the President of the United States.

That the Commissioner of Public Health may appoint an Assistant Commissioner of Public Health, who shall be a physician in good and regular standing in the medical profession, and skilled in sanitary science, and fix his salary at not to exceed $3,500 per annum and all actual and necessary traveling expenses incurred in the performance of his duties as Assistant Commissioner in said Department. All officers and persons in the service of the United States, detailed to perform any duty under the provisions of this act, or any existing act, of the Congress of the United States providing for quarantine against diseases, or to prevent diseases from spreading within the United States, shall not receive any additional compensation except for actual and necessary expenses incurred in the performance of such duties, such expenses to be approved by the Commissioner of Public Health or his assistant, and to be paid on vouchers provided by the Department of the Treasury.

It shall be the duty of the Commissioner of Public Health to preside at all meetings of the said advisory council, and in case of his absence on account of illness or any other unavoidable cause, it shall be the duty of the Assistant Commissioner of the Department so to preside.

Sec. 3. That the Department of Public Health hereby created shall succeed to all the powers and duties now and heretofore conferred upon the Marine-Hospital Service, or any officer thereof, by any law of Congress, except as hereinafter provided, and shall occupy the building now occupied by the Marine-Hospital Service for its offices, and shall have under its exclusive control and management all offices, officers, laboratories, appurtenances and property of whatever name and nature, which are lawfully in possession of the said Marine-Hospital Service at the time of the passage of this act, but it is hereby provided that there shall be in said department a bureau to be known as "The Bureau of the Marine-Hospital Service," which shall be under the exclusive control of the Commissioner of Public Health, and all laws governing the appointment to official positions in said Marine-Hospital Service, and to promotions in said service, shall continue in full effect, and all funds now or hereafter appropriated for the Marine-Hospital Service by Congress shall continue to be disbursed under the supervision of the Commissioner of Public Health by the direction of the Secretary of the Treasury until otherwise provided by law, it being the intent and purpose of this act to continue the Marine-Hospital Service and to confer all duties relating to quarantine and the public health upon the department hereby created.

Sec. 4. That whenever any department of government, or the executive of any state or territory, or the Commissioners of the District of Columbia, or the health authorities of any State, shall request information from the Department of Public Health in regard to any matter pertaining to the protection or promotion of the public health, said department shall promptly furnish such information as it may have on record, together with any necessary or pertinent advice; and whenever any information shall be received by the department which the interests of the public health require should be promptly communicated to any department of the government, or to any state officer, such information shall be forthwith furnished to the respective department or officer.

Sec. 5. That the department shall take such action, by adopting and enforcing such rules, and by correspondence or conference, as will tend most effectually to secure the coöperation of State, municipal, and local boards of health in establishing and maintaining an efficient and accurate system of notification of the existence and progress of contagious and infectious diseases, and of vital statistics in the United States, and said department shall also, by coöperation with the proper health authorities of foreign nationalities and municipalities, endeavor to extend to the United States a reliable system of international notification of the existence and progress of such diseases as cholera, yellow fever, typhus fever, smallpox, bubonic plague, or any other dangerous or contagious disease which may, in the judgment of the department, seem advisable to consider.

Sec. 6. That in sending notifications to, and receiving reports from, the different States or Territories in the United States, the department shall conduct all correspondence through the State and Territorial health authorities, and all information intended for local use received by the State and Territorial health authorities, shall by them be forwarded to the local boards of health, or health authorities, within their jurisdiction, and all reports and information received from local health authorities, and local boards of health, shall pass through the office of the State or Territorial health authorities to the said Department of Public Health.

Sec. 7. That the department shall, when in its judgment it may deem it necessary and proper, make such additional rules and regulations as are necessary to prevent the introduction of infectious and contagious diseases into the United States from foreign countries, or into one State or Territory, or the District of Columbia, from another State or Territory or the District of Columbia, and when said rules and regulations have been made they shall be promulgated by the said department subject to the approval of the advisory council, and the President of the United States, and enforced by the sanitary authorities of the States, Territorities, municipalities, and local boards of health, where the State, Territorial, municipal, or local health authorities will undertake to execute and enforce them, but if the State, Territory, municipal, or local health authorities shall fail or refuse to enforce such rules and regulations, the President of the United States shall execute and enforce the same, and adopt such measures as in his judgment shall be necessary to prevent the introduction or spread of such diseases, and may detail or appoint officers for that purpose.

Sec. 8. That it shall be the duty of said department to perform all the duties in respect to quarantine and quarantine regulations, which are provided for by this act, or by any existing act of the Congress of the United States, and all duties in regard to the prevention and spreading of diseases throughout the United States as provided for in this act, and to obtain information of the sanitary condition of foreign ports and places from which contagious and infectious diseases are, or may be, imported into the United States, and to this end the consular officers of the United States at such ports and places as shall be designated by the Commissioner of Public Health, shall make weekly reports to the department of the sanitary condition of the ports and places at which they are respectively stationed, according to such forms as the Department of Public Health shall prescribe; and the Commissioner of Public Health shall also obtain, through all sources accessible, including State and Territorial sanitary authorities throughout the United States, weekly reports of the sanitary condition of ports and places within the United States, and shall prepare, publish, and transmit to collectors of customs, and to State and Territorial boards of health, and through them to municipal health officers, and other sanitarians, weekly abstracts of the consular sanitary reports, and other pertinent information received by him, and shall also, as far as he may be able, by means of voluntary coöperation of State and Territorial authorities, and through them municipal authorities, public associations, and private persons, procure information relating to the climatic and other conditions affecting the public health.

Sec. 9. That it shall be unlawful for any merchant ship or other vessel, from any foreign port or place, to enter any port of the United States, except in accordance with the provisions of this act, and with such rules and regulations of State, Territorial and municipal health authorities as may be made in pursuance of, or consistent with, this act; and any such vessel which shall enter, or attempt to enter, a port of the United States in violation thereof, shall, upon conviction of the Master thereof, forfeit to the United States a sum to be awarded in the discretion of the court, not exceeding $5,000, which shall be a lien upon said vessel to be recovered by proceedings in the proper district court in the United States. In such proceedings the United States District Attorney for such district shall appear on behalf of the United States, and all such proceedings shall be conducted in accordance with the rules and laws governing cases of seizure of vessels for violation of the revenue laws of the United States.

That any vessel, at any foreign port, clearing for any port or place in the United States, shall be required to obtain from the consul, vice-consul, or other consular officer of the United States at the port of departure, or from the medical officer, where such officer has been detailed by the President of the United States for that purpose, a bill of health in duplicate, in the form prescribed by the Department of Public Health, setting forth the sanitary history and condition of said vessel, and that it has in all respects complied with the rules and regulations in such cases prescribed for securing the best sanitary condition of the said vessel, its cargo, passengers and crew; and said consular, or medical, officer is required before granting such duplicate bill of health, to be satisfied that the matters and things therein stated are true; and for his services in that behalf he shall be entitled to demand and receive such fees as shall by lawful regulations be allowed, to be accounted for as is required in other cases.

The President of the United States in his discretion is hereby authorized to detail any medical officer of the government to serve in the office of the consul at any foreign port for the purpose of furnishing information, and making the inspection, and giving the bills of health hereinbefore mentioned. Any vessel clearing and sailing from any such port, without such bill of health, and entering any port of the United States shall, upon conviction of the Master thereof, forfeit to the United States not more than $5,000, the amount to be determined by the court, which shall be a lien on the same to be recovered by proceedings in the proper district court of the United States. In such proceedings the United States District Attorney for such district shall appear on behalf of the United States; and all such proceedings shall be conducted in accordance with the rules and laws governing cases of seizure of vessels for violation of the revenue laws of the United States.

Sec. 10.—That the Commissioner of Public Health shall from time to time, issue to the consular officers of the United States and to the medical officers serving at any foreign port, and otherwise make publicly known, the rules and regulations made by him, to be used and complied with by vessels in foreign ports, for securing the best sanitary condition of such vessels, their cargoes, passengers and crew, before their departure for any port in the United States, and in the course of the voyage; and all such other rules and regulations as shall be observed in the inspection of the same on the arrival thereof at any quarantine station at the port of destination, and for the disinfection and isolation of the same, and the treatment of the cargo and persons on board, so as to prevent the introduction of cholera, yellow fever, leprosy, bubonic plague, smallpox, or other contagious or infectious diseases; and it shall be unlawful for any vessel to enter said port to discharge its cargo or land its passengers except upon a certificate of the health officer at such quarantine station, certifying that said rules and regulations have in all respects been observed and complied with, as well on his part as on the part of the said vessel and its master, in respect to the same and to its cargo, passengers and crew; and the master of every such vessel shall produce and deliver to the collector of customs at said port of entry, together with the other papers of the vessel, the said bills of health required to be obtained at the port of departure, and the certificate herein required to be obtained from the health officer at the port of entry; and that the bills of health herein prescribed shall be considered as part of the ship's papers, and when duly certified to by the proper consular officer, or other officer of the United States, over his official signature and seal, shall be accepted as evidence of the statements therein contained in any court of the United States.

Sec. 11.—That the Commissioner of Public Health shall, and at such times as he may deem necessary, examine the quarantine regulations of all State and municipal boards of health, or detail an officer of the said department to make such examinations, and shall coöperate with and aid all State, municipal and local boards of health in the execution and enforcement of the rules and regulations made by the Department of Public Health under the provisions of this act, or any other act of the Congress of the United States providing for a quarantine against disease, and to prevent the introduction of contagious and infectious diseases into the United States from foreign countries, and into one State or Territory, or the District of Columbia, from another State or Territory, or the District of Columbia; and all rules and regulations made shall operate uniformly and in no manner discriminate against any port or place; and at such ports and places within the United States as have no quarantine regulations under State, Territorial or municipal authority, where such regulations are, in the opinion of the Commissioner of Public Health, necessary to prevent the introduction of contagious and infectious diseases into the United States from foreign countries, or into one State or Territory, or the District of Columbia, from another State or Territory, or the District of Columbia, and at such ports and places within the United States where quarantine regulations exist under the authority of the State, Territory, or municipality which, in the opinion of the Commissioner of Public Health, are not sufficient to prevent the introduction of such diseases into the United States, or into one State or Territory or the District of Columbia, from another State or Territory or the District of Columbia, the Commissioner of Public Health, if in his judgment it is necessary and proper, shall, with the advice and approval of the advisory council, make such additional rules and regulations as may be necessary to prevent the introduction of such diseases into the United States from foreign countries, or into one State or Territory, or the District of Columbia, from another State or Territory or the District of Columbia, and when said rules and regulations have been made and approved by the President of the United States, they shall be promulgated by the Commissioner of Public Health and enforced by the sanitary authorities of the State, Territories and municipalities, where the State, Territorial or municipal health authorities will undertake to execute and enforce them; but if the State, Territorial or municipal authorities shall fail or refuse to enforce said rules and regulations, the President of the United States shall empower the Commissioner of Public Health to execute and enforce the same and adopt such measures as in his judgment shall be necessary to prevent the introduction or spread of such diseases, and may detail or appoint officers for that purpose. The Commissioner of Public Health shall make such rules and regulations, with the advice and consent of the advisory council, and approved by the President of the United States, as are necessary to be observed by vessels at the port of departure and on the voyage, where such vessels sail from any foreign port or place in the United States, to secure the best sanitary condition of such vessel, her cargo, passengers and crew, which shall be published and communicated to, and enforced by, the consular officers of the United States. None of the penalties herein imposed shall attach to any vessel, or owner, or officer thereof, until a copy of this act, with the rules and regulations made in pursuance thereof, has been posted up in the office of the consul, or other consular officer of the United States, for ten days, in the port from which said vessel sails; and the certificate of such consul, or consular officer, over his official signature, shall be competent evidence of such posting in any court of the United States.

Sec. 12.—That on the arrival of an infected vessel at any port not provided with proper facilities for treatment of the same, the Commissioner of Public Health may remand said vessel, at its own expense, to the nearest National or other quarantine station, where accommodations and appliances are provided for the necessary disinfection and treatment of the vessel, passengers and cargo; and after treatment of any infected vessel at a National quarantine station, and after certificate shall have been given by the United States quarantine officer at such said station that the vessel, cargo and passengers are each and all free from infectious disease, or danger of conveying the same, said vessel shall be admitted to entry to any port of the United States named within the certificate. But at any ports where sufficient quarantine provision has been made by State, Territorial or local authorities, the Commissioner of Public Health may direct vessels bound for said ports, to undergo quarantine at such said State, Territorial or local station.

SEC. 13.—That whenever it shall be shown to the satisfaction of the President of the United States that by reason of the existence of cholera, yellow fever, or other infectious or contagious diseases in a foreign country, there is danger of the introduction of the same in the United States, and that notwithstanding the quarantine defense, this danger is so increased by the introduction of persons or property from such country that a suspension of the right to introduce the same is demanded in the interest of the public health, the President shall have power to prohibit, in whole or in part, the introduction of persons and property from such countries or places as he shall designate, and for such period of time as he may deem necessary.

SEC. 14.—That whenever the proper authorities of a State or Territory shall surrender to the United States the use of the buildings and disinfecting apparatus at a State quarantine station, the Commissioner of Public Health shall be authorized to receive them and to pay a reasonable compensation to the State or Territory for their use, if in his opinion they are necessary to the United States.

SEC. 15.—That whenever necessary there shall be purchased or erected, under the orders of the Commissioner of Public Health, with the approval of the Secretary of the Treasury, suitable warehouses with walls and enclosures, where merchandise may be unladen and deposited from any vessel which shall be subject to a quarantine or other restraint, pursuant to the health laws of any State, at such convenient places therein as the safety of the public revenue and the observance of such health laws may require.

SEC. 16. That whenever the cargo of a vessel is unladen at some other place than the port of entry or delivery under the foregoing provisions, all the articles of such cargo shall be deposited, at the risk of the parties concerned therein, in such public or other warehouses or enclosures, as the collector of customs shall designate, there to remain under the joint custody of such collector and of the owner or master, or other person having charge of such vessel, until the same are entirely unladen or discharged, and until the articles so deposited may be safely removed without contravening such health laws. And when such removal is allowed, the collector having charge of such articles may grant permits to the respective owners or consignees, their factors or agents, to receive all merchandise which has been entered, and the duties accruing upon which have been paid, upon the payment by them of a reasonable rate of storage, which shall be fixed by the Secretary of the Treasury for all public warehouses and enclosures.

SEC. 17.—That the master of any vessel employed in transporting passengers between the United States and Europe, is authorized to maintain good discipline, and such habits of cleanliness among the passengers as will tend to the preservation and promotion of health; and to that end he shall cause such regulations as he may adopt for this purpose to be posted up, before sailing, on board such vessel in a place accessible to such passengers, and shall keep the same so posted up during the voyage. Such master shall cause the apartments occupied by such passengers to be kept at all times in a clean, healthy state; and the owners of every such vessel so employed are required to construct the decks, and all parts of the apartments, so that they can be thoroughly cleansed; also to provide a safe, convenient privy or water-closet for the exclusive use of every one hundred passengers. The master shall also, when the weather is such that the passengers can not be mustered on deck with their bedding, and at such other times as he may deem necessary, cause the deck occupied by such passengers to be cleansed with chlorid of lime, or some other equally efficient disinfecting agent. And for each neglect or violation of any of the provisions of this section, the master and owner of any such vessel shall, upon conviction thereof, be severally liable to the United States in a penalty of one hundred dollars, to be recovered in any circuit or district co within the jurisdiction of which such vessel may arrive, or from which she is about to depart, or at any place where the owner or master may be found, or to imprisonment of not less than thirty days, or by both fine and imprisonment, in the discretion of the court.

SEC. 18.—That whenever the evidence shall appear conclusive to the President of the United States that cholera, yellow fever, typhus fever, typhoid fever, smallpox, diphtheria or other plague, exists in any State or Territory, or in the District of Columbia, to such an extent that there is great danger of the spread of such disease into other States, Territories, or the District of Columbia, by means of vessels and vehicles engaged in the transportation of goods, passengers, and the United States mail, by land and water, or by persons traveling, on foot or otherwise, he is hereby authorized to call together the Commissioner of Public Health and advisory council to take such action as may be necessary to prevent the spread of such disease from one State or Territory into another, or from any State or Territory into the District of Columbia, or from the District of Columbia into any State or Territory, and the Commissioner of Public Health shall make such rules and regulations, by and with the advice and consent of the advisory council, and the approval of the President of the United States, as may be necessary to meet the emergency, and all such rules and regulations shall have the force of law, and supersede all other rules, laws or regulations for the time being at the place designated, and any one violating any such rules and regulations shall, upon conviction thereof, be subject to arrest and imprisonment for a period of not less than thirty days. The Commissioner of Public Health may temporarily employ such inspectors and other persons as may be necessary to execute all rules and regulations adopted as aforesaid to stamp out and prevent the spread of such disease.

SEC. 19.—That the Commissioner of Public Health or any one appointed by him may, with the approval of the Secretary of the Treasury, select suitable localities for establishing stations on rivers and other lines of interstate commerce and travel by railroads, and may cause to be erected necessary temporary buildings for the disinfection of passengers, baggage, cargoes, vessels and vehicles, and may enforce such rules and regulations relating thereto as may have been, or may be, prescribed therefor.

SEC. 20.—That the Secretary of the Treasury is authorized whenever a conformity to such quarantines and health laws requires it, and in respect to vessels subject thereto, to prolong the terms limited for the entry of the same, and the report of the entry of their cargoes, and to vary or dispense with any other regulations applicable to such reports or entries. No part of the cargo of any vessel shall, however, in any case be taken out or unladen therefrom otherwise than is allowed by law, or according to the regulations and rules adopted and promulgated by the Commissioner of Public Health under the provisions of this act, or any existing act.

SEC. 21.—That the Commissioner of Public Health and the advisory council, created under this act, shall devise such means and methods as they may deem most effective to control and exterminate all domestic diseases transmitted by contact, such as phthisis pulmonalis or tuberculosis, diphtheria, scarlet fever, smallpox, leprosy and all diseases dangerous to the public health. That the said Department of Public Health may, under the direction of the Commissioner of Public Health, make investigations, both in the United States and, if necessary, in foreign countries, into the nature, origin and prevention of contagious, epidemic and other diseases, and the causes and conditions of particular outbreaks of disease in the United States, and in order that said experiments may be made, the Commissioner of Public Health shall, if necessary, enlarge the laboratories of the Marine Hospital Service, erect and maintain such other laboratories as may be necessary, and to equip said laboratories with the best appliances obtainable for investigation into the causes of disease and how to prevent and obliterate the same.

SEC. 22.—That the Commissioner of Public Health may engage the services of experts, not to exceed six in number, in such laboratories in the United States as are best adapted by location, equipment or special fitness, to aid the Department of Public Health in making investigations, the pay to be allowed such experts to be fixed by the Commissioner of Public Health. It shall also be the duty of the said department to investigate the best method for the disposal of sewage, the protection of public water supplies, to ascertain the best sanitary methods, to investigate all matters which relate to the public health, and to gather statistics relating to marriages, births, and deaths, and cause of death, and when the same [illegible] be done without prejudice to [illegible] [illegible]ublic se[illegible] [illegible] of the United [illegible] may [illegible] [illegible]ts of the government for temporary duty to act under the direction of said department, to carry out the provisions of this act, and all other acts of the Congress of the United States providing for a quarantine against disease and to prevent the spread of any disease within the United States.

Sec. 23.—That the Secretary of the Department of Agriculture, and the Commissioner of the Department of Labor shall respectively furnish for the use of the Department of Public Health such information as they shall from time to time gather upon the following and kindred subjects, to-wit: 1. The investigation of foods; also drugs, liquors and wines, their standard of purity and their adulterations. 2. The transmission of disease from animal to man and *vice versa*, such as tuberculosis, glanders, etc. 3. The statistics of climate with relation to infectious and other diseases. 4. The statistics and conditions relating to consanguineous and other marriages liable to produce physically and mentally defective offspring; and any information leading to race improvement through better marriage selection than obtains at present. 5. The statistics relating to child labor and to confined and unhealthy occupations, etc.

Sec. 24.—That it shall be lawful for the Commissioner of Public Health, when in his judgment it may seem necessary to confer upon any municipal or local health officer, or health authority, through the State or Territorial authorities in which he may have jurisdiction, power also to enforce the provisions of this act and any rules and regulations made in pursuance thereof, and any person who shall knowingly disobey or violate any order, rule or regulation made pursuant to the authority herein conferred, shall, upon conviction thereof, be deemed guilty of a misdemeanor punishable by a fine of not less than $500 or by imprisonment for a period of not less than one year.

Sec. 25.—That the Commissioner of Public Health shall make an annual report of the operations of the Department to Congress with such recommendations as he may deem important to the public interest; and said report, if ordered to be printed by Congress, shall be done under the direction of the Commissioner of Public Health, and that all mail matter of whatever class relative to the Department of Public Health and its duties, and addressed to the Commissioner of Public Health and indorsed "Official Business, Department of Public Health," or mailed by said department, shall be transported free of postage; and if any person shall make use of such indorsement to avoid the payment of postage in his private letter, package or other matter in the mail, the person so offending shall, upon conviction thereof, be deemed guilty of a misdemeanor and be subject to the penalty prescribed by the existing law.

Sec. 26.—That the Commissioner of Public Health is authorized to appoint for duty not to exceed six sanitary inspectors, at a salary not to exceed $1,800 per annum each, and their necessary actual traveling expenses; at least two of these inspectors shall be experts in quarantine matters, two shall be skilled bacteriologists, and one shall be an expert statistician. The Commissioner of Public Health is authorized to employ one chief clerk at a salary of $1,800; one clerk of class three at $1,400; and one clerk of class two at $1,400; and four clerks at $1,000 each, one messenger at $800, one stenographer at $800, one watchman at $600 per annum.

Sec. 27.—That any officer, or person acting as an officer, or agent at any quarantine station, or other person employed to aid in preventing the spread of disease, who shall wilfully violate any quarantine laws of the United States, any of the provisions of this act, or any of the rules and regulations made and promulgated as provided for in this act, or any other act of the Congress of the United States providing for and regulating quarantine against disease, or to aid and prevent the spread of any disease within the United States, or any lawful order of his superior officer, or officers, shall be deemed guilty of a misdemeanor, and upon conviction thereof shall be punished by a fine of not more than $500, or imprisonment for not more than one year or both, in the discretion of the court.

Sec 28. - That when any common carrier or officer, agent, or employe of any common carrier, shall wilfully violate any of the quarantine laws of the United States, or the rules and regulations made and promulgated as provided for in this act, or any other act of the Congress of the United States regulating and maintaining a quarantine against disease, and to prevent the spread of disease within the United States, such common carrier, officer, agent, or employe shall be deemed guilty of a misdemeanor, and shall upon conviction thereof be punished by a fine of not more than $500 or imprisonment for not more than two years, or both, in the discretion of the court.

Sec. 29.—That any person who shall wilfully violate any rule or regulation made and promulgated by authority of this act, or any other act of the Congress of the United States, providing for a quarantine against disease, and to prevent the spread of any disease within the United States, shall be deemed guilty of a misdemeanor, and upon conviction thereof shall be punished by a fine of not more than $500 or imprisonment for not more than two years, or both, in the discretion of the court.

Sec. 30.—All convictions for the violation of any of the provisions of this act, or any other act of the Congress of the United States, providing for a quarantine against disease, and to prevent the spread of any disease within the United States, shall be tried in the district wherein the offense was committed, and it shall be the duty of the United States district attorney for such district to appear on behalf of the United States, and all trials and proceedings shall be conducted in accordance with the rules and laws governing criminal cases triable in the United States courts.

Sec. 31.—That all rules made and promulgated, adopted and published pursuant to the provision of an act entitled "An act granting additional quarantine powers and imposing additional duties upon the Marine Hospital Service," approved Feb. 15, 1893, shall remain in force until the same are annulled, changed, or modified, as provided for by this act, and other acts of Congress providing for quarantine against diseases, and the spread of any disease within the United States.

Sec. 32.—That all rules and regulations made and promulgated to enforce the provisions of this act, or any other act of the Congress of the United States, providing for a quarantine against disease, and to prevent the spread of any disease within the United States, shall be approved by the President of the United States, and when approved by him shall have all the force and effect of law.

Sec. 33.—That the Commission of Public Health shall annually submit to the Secretary of the Treasury, for transmission to Congress, estimates of the expense necessary to maintain properly the Department of Public Health for the ensuing year. That there shall be, and hereby is, appropriated out of the moneys in the Treasury and not otherwise appropriated, the sum of $75,000 for the purpose of this act. The sum of $1,000,000 already appropriated and known as an emergency fund to be expended by the President of the United States or the balance thereof not already expended, shall be a fund and held and expended at the discretion of the President of the United States in the execution of the provisions of this act.

Sec. 34.—Sec. 1, Chapter 19, Supplement to the Revised Statutes, Vol. 1, second edition, revised and continued (page 637) is hereby amended so as to read as follows:

Sec. 1. *Be it enacted, etc.*, That medical officers of the Marine Hospital Service of the United States shall hereafter be appointed by the President, by and with the advice and consent of the Senate, and no person shall be so appointed until after passing a satisfactory examination in the several branches of medicine, surgery and hygiene before a board of medical officers of said service. Said examination shall be conducted according to rules prepared by the Commissioner of Public Health and approved by the advisory council and the President.

Sec. 35.—Sec. 4,796 and 4,082, Revised Statutes of 1878, Chapter 66, laws of 1878, Supplement to Revised Statutes, Vol. 1, second edition, revised and continued: "An act to prevent the introduction of contagious or infectious diseases into the United States."

Paragraph 9, chapter 130, laws of 1875, same supplement: "An act making appropriations for sundry civil expenses of the Government for the fiscal year and for other purposes."

Sec. 7, chapter 156, laws of 1875, same supplement: "An act to promote economy and efficiency in the Marine Hospital Service."

Chapter 51, laws of 1890, same supplement: "An act to prevent the introduction of contagious diseases from one State to another, and for the punishment of certain offenses."

Paragraph 5, chapter 195, passed July 16, 1892.

Paragraph 3, chapter 211, passed March 3, 1893.

Paragraph 6, chapter 174, passed July 31, 1894.

Chapter 300: An act amendatory to the aforesaid, passed Aug. 18, 1894

Paragraph 9, chapter 177, passed March 2, 1895.

Chapter 114, Supplement of the Revised Statutes, Vol. 2, laws of 1893: 'An act granting additional quarantine powers and imposing additional duties upon the Marine Hospital Service," and all other acts, or parts of acts, inconsistent herewith, or repugnant to the provisions of this act, are hereby repealed.

Sec. 36.—This act shall take effect and be in force sixty days after its passage, within which time the Commissioner of Public Health and Assistant Commissioner of Public Health may be appointed.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
Per Annum, in Advance $5.00
Foreign Postage 1.75
Single Copies . . . . 10 Cents.

In requesting change of address, give *old* as well as new location. Subscriptions may begin at any time and be sent to

The Journal of the American Medical Association,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly Journal of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the Journal office.

All communications and manuscript of whatever character, intended for publication in the Journal, should be addressed to the *Editor*, and all communications relative to the business of the Journal, proof sheets returned, or in regard to subscriptions, should be addressed to The Journal of the American Medical Association, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this Journal.

SATURDAY, OCTOBER 9, 1897.

ARE OUR BACTERIOLOGIC METHODS COMPLETE AND SCIENTIFIC?

The recognition of pathologic bacteria is now all important and in many disorders an essential part of medical diagnosis. There is no doubt as to the advantage in knowledge and accuracy that has been gained by the methods now employed, and medical bacteriologists at least have generally come to consider them as fully meeting all scientific demands. It is true that questions of identity of bacterial species often arise, and that uncertainty exists in regard to some practically important points, but there are apparently few who are inclined to doubt the prevalent methods of research as being fully sufficient for their ultimate solution. Any charge that the commonly accepted procedures in the study of these organisms are not in accordance with the approved methods of scientific investigation and liable to give imperfect of not actually misleading notions as to their real character and behavior under some very possible circumstances would probably be a surprise to many bacteriologists and would be received with doubt if not with absolute discredit.

This, however, is just the accusation brought against the prevailing method of bacteriologic study by no less eminent an authority than Professor H. Marshall Ward in his opening address as president of the Botanical Section of the British Association for the Advancement of Science at its late Toronto meeting. He showed how the earlier bacteriologists, Cohn, De Bary and Brefeld, followed a different plan from that now in vogue, and one more in accordance with approved scientific ideas; they sought to study individuals of the species, to isolate single spores under the microscope, and to trace continuously their growth through the fully developed form to the production again of spores; in short, to study the life history of the individual bacterium, which is the only true method in natural history. This was a difficult task and many mistakes were made by the earlier workers in the field, and had investigators been confined to this method alone it is not probable that bacteriologic diagnosis would even now be as important and efficient as it has been for a number of years past. Undoubtedly the introduction of the colony method of culture on gelatin and other substances, by Koch in 1881, was in its way a great stimulus to investigation and is responsible for the great extension and advance made since then in the practical utilization of its results. The earlier investigators, though on the right track, with their more imperfect appliances, fell into many errors, and the rapid method of making wholesale cultures was very naturally heralded as a great step in advance and, as it has been called, "the Columbus egg of bacteriology." Nevertheless, as Professor Ward says, "it turned the current of investigation of bacteria from the solid and trustworthy ground established by Cohn, Brefeld and De Bary, into an entirely new channel and one that really abandons the proper method of morphologic study, to satisfy itself with what is in comparison a superficial and untrustworthy one. While the more difficult method of studying the individual bacterium from spore to spore is subject to error from defects of technic and observation, it is nevertheless an ultimately practicable one, and the only one by which disputed points can be finally and satisfactorily solved. The importance of this can be shown by the testimony of Koch himself as quoted by Eisenberg in the preface to his "Bacteriological Diagnosis." He says: "The further bacteriologic investigation advances, the more obvious becomes the fact that it is absolutely unallowable to base our diagnosis of a given bacterium upon anything short of a careful consideration of all its characters and properties," and these are not to be ascertained beyond question by studying bacteria only *en masse* and neglecting their possible individual peculiarities. These are, in fact, implied in their behavior and modes of growth in the aggregated colonies, which must depend upon structural peculiarities of the individual members. The present prevalent method is, as Ward points out, only comparable to a botanist satisfying himself with observation of oaks, for example, as seen in masses in a forest, or grass and clover as they appear in a general view of a meadow, or, to approach nearer to the actual condition, to classifying molds by the appearance of the patches. There is no parallel to this in natural history, unless we admit as such the species of corals and sponges, but here the special indiv organisms are not neglected by the naturalist and wide distinctions are made between apparently similar forms. Species are not made, as in bacteria, exclusively on their behavior in aggregated masses, observed only as such, or if so, are not considered final and absolute determinations indicating an exhaustive knowledge of their peculiarities and life history, as appears to be the case in medical bacteriology. The quotation from Koch, which has been given above, which while literally accepted would seem to cover all the scientific demands, appears to have originally referred only to the imperfect method here deprecated: the observation of the form, color, marking and physiologic behavior of the colonies themselves and in different culture media, the popular and prevalent procedure, and the one almost, if not quite, exclusively taught in our medical text-books.

Professor Ward does not unduly disparage the results of the work of what he calls the test-tube school of bacteriologists; he admits that they have done a large amount of what may be considered valuable preliminary work, but he objects to and would discourage species-making merely on the data thus obtained. That his criticisms are just will probably be admitted, but it may be claimed that the present methods are amply sufficient for all medical needs and that without them the progress that has been made would have been impossible. The last of these propositions may be accepted as true without admitting the correctness of the other; imperfect knowledge may be better than none, but it can not be claimed to be all that is desirable. There is no need to say that our acquaintance with certain pathogenic bacteria is altogether insufficient, and any plan that will add to our knowledge of them ought to be welcomed. Even if it should be necessary to revise much of what has been written on medical bacteriology to meet all scientific demands the results ought to be worth the trouble they have cost. At present it is not satisfactory to be told that the deficiencies that exist in our knowledge in regard to many important points may be due to the inconsiderate acceptance of imperfect and insufficient methods of investigation.

However Professor Ward's address is received it should be a stimulus to more exact and thorough studies in medical bacteriology. In these minute but important investigations exact methods are as necessary as in any others, and while we may have to depend largely, as heretofore, upon the study of colony cultures, they need not be considered as the *ne plus ultra* of research of this particular branch of medical science.

THE ROLE OF GRANULATION TISSUE IN WOUND INFECTION WITH PATHOGENIC BACTERIA.

Nicolaus Afanassieff[1] of Moscow undertook to study the reactive changes that occur in granulation tissue when pathogenic bacteria are introduced into it. Some of the results obtained seem of more than ordinary interest and importance because they touch one of the most interesting questions in biology, namely, the nature of the struggle, if one may use the expression, of the organism against infection.

While very many investigators have studied the ability of granulation tissue to absorb alkaloids, various other chemic substances, and infusions of decomposing materials, none of the previous researches have taken up the question, under what conditions does infection with pathogenic bacteria of the whole organism take place through granulation tissue. Afanassieff made it his object to study the consequences of experimental infection of granulation tissue with various pathogenic microbes. After trying several methods it was found, by excising a small piece of skin with the subcutaneous tissue, and then pouring on a thick layer of collodion, that on removing the layer of collodion on the third or fourth day, there would be a nicely granulating surface; this method was found very serviceable in the case of such animals as mice, rabbits, chickens and pigeons. In the case of dogs and sheep a small wound was made and through this a sterile glass rod, about one and one-half inches long, was forced into the subcutaneous tissue. The wound was then sutured, covered with collodion, and after four days the sutures would be removed and the glass rod carefully extracted so as not to injure the granulations and cause hemorrhage. Under all circumstances great care was always taken not to experiment upon bleeding surfaces, lest the microbes should be introduced directly into the circulation. The microbes experimented with were principally anthrax bacilli and the vibrio Metchnikoff. The virulence of the cultures was carefully determined beforehand and only typical and highly virulent cultures were used. A small quantity was then placed on the granulating surface and simultaneously an equal amount of the same culture was placed on a fresh wound on the same place of the control animal as the granulating wound on the original animal. Subsequently the juice of the granulation tissue and the granulation tissue itself were examined microscopically and bacteriologically. The virulence of the cultures obtained from the granulation tissue was carefully determined and cultures were made from the internal organs of the animals that perished.

Without introducing the protocols and statistics of the experiments, it may be allowed to say that they show that animals infected with pathogenic microbes placed on an uninjured granulating wound, do not succumb; that a general infection of the organism does not take place; the bacteria placed on the granulations do not, if these are healthy, reach the internal organs. Furthermore, that such animals become almost wholly immune to subsequent infection with fully virulent cultures introduced through fresh wounds. Inasmuch as bacteria did not enter the organism when placed on granulating wounds, it must be concluded that the absorption of some products of the reaction between the bacteria and the granulation tissue produced the more or less well marked immunity.

---

[1] Ziegler's Beiträge, Bd. xxii, Heft 1, 1-6.

The examination of the infected granulation tissue by means of cover-glass preparations of the juice, as well as the suitably prepared sections of the tissue itself, shows in brief that the bacteria undergo a progressive destruction in the form of various degenerations and disintegrations. This process of destruction was observed to begin so early that but little, *often no, signs of phagocytosis were evident; but as* the bacterial disintegation became more marked phagocytosis became more and more pronounced. The earliest evidences of degeneration of the bacteria consists in irregular or poor staining in ordinary solutions; in the anthrax bacilli fine granules would also appear; more rarely the bacteria would swell up into worm-like, irregularly and poorly stained, often thin threads.

Another form of degeneration of the bacteria was observed in a failure to stain with basic dyes and, on the other hand, affinity for acid coloring matters, such as eosin; this degeneration was noted in the free as well as the intracellular bacteria, and a few times as early as fifteen minutes after the placing of the bacteria on the granulation. BORDET, METCHNIKOFF and others have described such *eosinophile* bacteria in the interior of cells and have interpreted the change in the affinity for stains as evidences of phagocytosis. Furthermore, AFANASSIEFF also observed granular, bacterial detritus, staining red with eosin, in the interior of the leucocytes. Similar changes also occurred when bacteria were placed on fresh wound surfaces, but much later and in less pronounced degree. It was noted that when bacteria such as mentioned were placed on the wounds a free exudation of serum took place, lasting a few hours. These observations go to show that in granulation tissue bacteria may begin to disintegrate under the influence of the tissue juice without any participation of the phagocytic leucocytes. AFANASSIEFF interprets this as meaning that the phagocytosis plays either no part or merely a secondary one in the struggle of the organism against infection; it would seem *that this might be true as regards actual phagocytosis* in this case, but it must not be forgotten that the extracellular, bactericidal action of the serum may, in the last instance, depend upon substances produced or liberated by leucocytes and other cells.

In conclusion it may be allowed to mention the more important conclusions to be drawn from AFANASSIEFF'S research:

1. General infection of the organism with pathogenic bacteria does not take place through healthy, uninjured young granulation tissue.

2. Animals experimented on by placing pathogenic bacteria on granulating wounds become less susceptible than normally to a subsequent infection with fully virulent cultures through fresh wounds.

3. Pure cultures made from infected granulation tissue ten to twelve hours after infection, were found to be more or less attenuated.

4. Pathogenic bacteria placed on granulating wounds undergo a progressive disintegration under the action of the tissue juice, the processes of phagocytes playing a secondary role.

Finally, it should be mentioned that these observations are of *direct practical interest* because they indicate that healthy granulation tissue forms a protective wall against general infection; consequently, the surgeon should treat granulating surfaces with great tenderness and care, so as *not to produce injuries to* the young tissue through which infection would be more liable to occur.

ON THE OCCURRENCE OF THE FAT-SPLITTING FERMENTS IN PERITONEAL FAT NECROSES AND THE HISTOLOGY OF THESE LESIONS.

The interesting subject of fat necrosis in its relation to certain diseases of the pancreas has been commented upon in these editorial columns before. The coincidence of disease of the pancreas with fat necrosis in the peritoneum and elsewhere has lent support to the view that a *definite relation of cause and effect* must obtain between the gland and the changes in the fat. LANGERHANS[1] was the first to furnish experimental proof of this assumption. He injected sterile pulp of fresh pancreas into the perirenal tissue of a rabbit, with the result of causing inflammatory changes and some necrosis of the fat. Subsequent experiments by DETMER, HILDEBRAND, KÖRTE and WILLIAMS[2] have established: 1, that the secretion of the pancreas may enter the peritoneal cavity without setting up diffuse inflammation; 2, that in certain instances free, sterile pancreas or the pancreatic secretion causes focal fat necrosis; and 3, the element of *infection plays an insignificant, if not unessential,* part.

In order to reach more exact *notions of this pathogenic* action of the pancreatic secretion, FLEXNER[3] attempted to demonstrate the *presence of the fat-splitting* ferment in areas of necrosis and its absence from normal human fat. Without going into details as to chemic methods employed for demonstrating this ferment, it will suffice to state that positive reactions were obtained in a human case of widely disseminated necroses and in areas of fat necrosis produced by ligating the veins and lacerating the pancreas in cats and dogs when the animals were killed no longer than three to four days after the operation. By excising necrotic foci on the third day or so it could be shown that the fat-splitting ferment which was then present would gradually disappear. Microscopic examination showed a marked difference between the early and the late lesions, the former, which contain the ferment, being acute, the others presenting pronounced evidences of cicatrization. Hence FLEXNER concludes that although it can not be affirmed that steapsin is the direct cause of the necrosis, yet such an assumption is rendered highly probable by its constant occurrence in the diseased areas, its absence from healthy fat and the nature of the pathologic changes. The escape of the pancreatic secretion into the peri- and para-pancreatic tissues must be regarded as the cause of the fat necroses, and this escape is made possible by lesions of the pancreas itself, and also by disturbances of its circulation.

---

[1] "Experimenteller Beitrag zur Fettgewebsnekrose," Virchow's Festschrift, 1891.

[2] All quoted by Flexner, "Trans. American Assoc. of Phys.," 1

[3] Loc. cit.

That necrosis of fat cells may occur from other causes is not excluded by these demonstrations. The cause of the necrosis found in the marrow of bones by PORFICK,[4] and in the subcutaneous and pericardial fat by CHIARI,[5] would be difficult to determine. Perhaps micro-organisms may play some part in these instances.

As regards the histologic changes, the main facts to be gleaned from the observations of PORFICK, FITZ. CHIARI, LANGERHANS and others are the following: The process begins with a decomposition of the neutral fat contained within the fat cells; the fluids are eliminated, the fatty acids remain behind as crystals which, after a time, unite with calcium to form insoluble lime salts; in the meantime the nuclei of the affected cells lose their affinity for stains, and soon the lime compounds form granules, rings and hyaline masses. Around such foci reactive inflammatory changes soon occur. Late proliferation of the fixed cells begin, the necrotic material gradually shrinks and finally it becomes completely replaced with connective tissue. When such changes occur around areas located in the connective tissue septa or parenchyma of the pancreas, small districts characteristic of interstitial pancreatitis result. Around the areas of necrosis produced experimentally, FLEXNER observed the occurrence of giant cells during the process of absorption.

From this brief review of some of the points in connection with fat necrosis, it would seem that our knowledge of its genesis is becoming more and more complete and satisfactory.

Let us have a Department of Public Health!

THE PUBLIC HEALTH BILL.

We print in this week's issue the Bill to establish a Department of Public Health, recommended by the Committee of our ASSOCIATION at Philadelphia. It has undergone, as will be noticed, very careful revision and it is believed it now meets the views of nearly all the members. The passage of the Bill may inconvenience some "coburghers" in official positions, but such considerations should not stand one moment in the way of the Bill, which is demanded by every consideration of humanity, by the voice of the united profession and by the dictates of common sense. The present calamitous epidemic is in itself an eloquent and terrible warning against the continuance of the present conditions. The Government quarantine was moved from Chandleur to Ship Island in spite of the lessons of the past, in spite of the law, in spite of the protest of the local health officer, and it is due to State Health Officer HARALSON of Mississippi, to say that during the past year he repeatedly protested against the reoccupancy of Ship Island quarantine. But this is a minor matter, notwithstanding the lives that have been lost in consequence of the sad blunder. The real need is for a Department of Public Health; at its head a commissioner who will not rule the Department by fear or favor; who will neither farm out the best positions in the service to personal favorites and sycophants, nor spend thousands of public money uselessly, and who will carry out the law with regard to conscience, right and the wishes of the people. At the proper time the Committee of the ASSOCIATION will urge the passage of this Bill, and at the suggestion of the Chairman of the Committee, Dr. WINGATE, we have had the bill electrotyped, so that any member desiring to write to his member of Congress or Senator in regard to it can have a copy sent to him by return mail. This is the way to secure the passage of the Bill, and now is the proper time when the whole country has been startled by the incompetence of the existing management.

Let us have a Department of Public Health!

THE "RECOGNITION" OF MEDICAL COLLEGES.

We observe in the columns of our esteemed contemporaries, the lay press, that frequent applications are made to the Board of Examiners, State Boards of Health, etc., for recognition by certain alleged medical colleges, some that are engaged either in selling diplomas outright or in giving them away after more or less protracted periods of study; usually less. We have had three letters within a week inquiring whether the "Independent" Medical College of Chicago was "recognized" or not. We have similar inquires concerning other alleged medical colleges. In our humble judgment the test of a medical college is its curriculum and its equipment for teaching students. Colleges that are unprovided with the modern facilities for teaching students should not be recognized by any board, and a requirement to that effect might well be the first test. The efficiency of the medical school is in proportion to the completeness or otherwise of its teaching outfit.

---

[4] Virchow's Archiv, lvi, 1872, p. 542.

[5] Prager Med. Wochenschrift, viii, 1883.

A school which is not fully equipped should be suppressed. So far as this "Independent" Medical College is concerned we do not believe it has any existence except on paper. Its graduates are to be considered as practicing medicine and obtaining money from their patients under false pretentions. This is, as we understand it, one of the concerns that offer to teach students at their own homes and prepare written questions and answers so that the student may not be put to the trouble of visiting the "college," but may have his degree conferred *in absentia*. The time has come when medical men should speak out in regard to certain half-baked institutions which flaunt their signs in the air like those announcing an approaching circus.[1] The mere desire of some half-educated person to be a "professor" should not of itself constitute any reason for recognizing a paper college, and that there are numerous medical colleges that are not demanded by the community or the necessities of the times is self-evident, and the profession itself should neither encourage students in going to these cheap John establishments nor give countenance to the persons engaged in keeping them up. So far as the "Independent Medical College" is concerned, we have never heard that they ever passed through the formality of giving lectures, and indeed it is quite probable that the kind of medicine taught by this particular diploma mill may come as well by mere contact with the sheepskin as by personal instruction of a venal "professor."

Let us hope that the State Boards of Examiners and licensing bodies everywhere may stimulate and encourage good schools by strong and vigorous rulings concerning teaching methods and appliances.

CORRESPONDENCE.

Drs. Rochester and J. R. Lemen on Paquin's Serum.

St. Louis, Sept. 29, 1897.

To the Editor:—Dr. Rochester's letter (Journal American Medical Association of September 18) in reply to my explanation of his unfair criticism of my work (Journal, August 31) is self-condemning. It does not demonstrate that he was justified, and that his efforts to find the truth about sero-therapy in tuberculosis were unbiased. It emphasizes the spirit of reckless indulgence which was manifest in his criticisms of a remedy, which, although not claimed by me to be perfect, is just what I have represented it to be, and was endorsed by many superior physicians. And it again shows a disposition to ruin rather than help those who sacrifice their existence in work to advance the sciences of medicine. I was humiliated to have to publish letters to explain my position, but I was justified; Dr. Rochester left no other recourse.

As to Dr. Joe Lemen of St. Louis, his good results with serum (Paquin) in tuberculosis are on record, and the records were written by himself and sent to me. The case of acute tuberculosis (the purest type of the disease) that recovered under this treatment, three years ago, under his care, is still living and well, and may be seen by the doctors who will go to the trouble to get at the facts. This is evidence that he wrote the truth then.

As to any special damage produced by antitubercle serum, such a thing does not occur in the hands of the careful physician. The usual untoward effects of sero therapy in general, occasionally noted after injections of the best diphtheria antitoxins of Germany, France and other countries, have rarely occurred with antitubercle serums. Deaths have occurred from the use of the most vaunted foreign antidiphtheric serums, but never with antitubercle serum (Paquin). We are frank enough in our literature and directions *to explain all the untoward effects known*. Such precautions are not generally taken by other antitoxin-producers. Thus advised, a conscientious physician will act properly and safely. Such serious accidents as are charged to some diphtheria serums, have never been reported as resulting from the use of any of the serums (for tuberculosis, tetanus, diphtheria, erysipelas, septicemia, puerperal fever, etc.) of the Paul Paquin Laboratories.

Dr. Lemen's comparison between the effects of antitubercle serum and Koch's old tuberculin amazes me. I thought Dr. Lemen knew that one is antitoxin, the product of immunized blood, and the other a toxin, the product of germ life in culture. These two agents are antipodes. They have opposite effects. No amount of unjust criticisms and unjust repudiation on the part of Dr. Lemen or any one else, no matter how good a physician, can outweigh the reports made by the scientific investigators of character who have made favorable reports. Such men can not be influenced by personal motives, or led by unscrupulous taskmasters. In self defence, the ground of the Doctor's attack might be given, did I not feel it indelicate and too ungenerous. This must be held as a *dernier ressort* should it become absolutely necessary to repel any more of the unkind criticisms and fallacies. I court fair criticisms of a scientific nature and gladly discuss them. They conduce to the advance of science. But mere denials or statements, or repudiations, without scientific backing, and without clinical records, particularly when inspired by unworthy motives, force upon me very painful duties. I can only meet them in part and can scarcely do justice to myself, without touching on personalities and giving offence. The consolation I have is the feeling that, as a rule, the readers realize quickly and appreciate the animus of an unfair critic. Paul Paquin, M.D.

An Aseptic Hospital for Yellow Fever.

Chicago, Oct. 4, 1897.

To the Editor:—During the epidemic of yellow fever in 1878, I suggested the plan of what might be called an aseptic hospital. The suggestion brought forth no fruit. It seems to me that the present is an opportune time to repeat my proposition. It is based on the assumption that the germ of the disease pervades the atmosphere and that, as a necessity, the patient is continually inspiring new quanta of the noxious toxin.

The suggestion is to prepare a building for hospital purposes so that it shall be air-tight. Air enters it and leaves it through channels comparable to the ordinary furnace and ventilating pipes. This air has been heated to a degree judged to be sufficient to destroy the yellow fever germ and subsequently cooled to a proper temperature. It is forced into the building by an air blast, and it is withdrawn from it by the suction force of a pump. In this way all parts of the sanitarium are supplied by air freed from germs of the disease. The exhaust air from the building is also on its way outward purified by heat.

---

[1] When we wrote this line we were not thinking of a nocturnal institution that has stretched a canvas sign across one of the principal streets of Chicago!

In the halls through which the building is entered an extra pressure of air is maintained, so that a strong blast from within prevents the entrance of the circumambient air when the doors are momentarily opened. It would be necessary, of course, in extemporizing such a sanitarium, that plants already erected and offering facilities for the contemplated arrangements should be pressed into service. Thus, gas works would be available for supplying heated air; and a manufactory of ice, or a cold storage warehouse, could be utilized for refrigerating it. John Bartlett, M.D.

Philadelphia County Medical Society.

Philadelphia, Sept. 25, 1897.

To the Editor:—Will you kindly announce on behalf of the Philadelphia County Medical Society that I have a considerable number of volumes of Transactions of the Medical Society of the State of Pennsylvania from 1889 to 1894, and some earlier ones in not perfect condition, which I shall be glad to furnish any one who will apply in person, or forward to any one who will accompany his application with the cost of packing and transportation, about 25 cents by mail.

Respectfully, Augustus A. Eshner, M.D.
Chairman Publication Committee.
224 S. Sixteenth St.

A Department of Public Health.

Amite City, La., Oct. 3, 1897.

To the Editor:—The urgent need for a Department of Public Health comes prominently to the front in this section of the country.

Arbitrary and irrational quarantine methods are the rule, frequently enforced by the persuasive shotgun, travel and traffic are interfered with, the mails are delayed or stopped altogether, running of trains upon trunk lines hampered, and every inconvenience imposed that the ingenuity of frightened people can devise.

Quarantine and safety would both be made sure, the needs of commerce and the general public alike protected, and the losses minimized, if all interests centered in a Department of Public Health, instead of allowing each community to regulate such matters for itself.

From a shut-in center, with all kinds of quarantine on all sides, I certainly echo your sentiments, let us have a Department of Public Health. Yours truly,

C. S. Stewart, M.D.

SOCIETY NEWS.

Detroit Medical and Library Association.—At the regular meeting of the Detroit Medical and Library Association September 13, Dr. Andrew P. Biddle read an interesting paper on "Some Common Types of Germ Dermatoses," in which he took up some of the common skin diseases that owed their existence to micro organisms and in which the bacteriologists made the diagnosis and the clinicians with their practical therapeutics proved the correctness of the etiologic factor. The author dwelt upon the subdivision of the schizomycetes, naming as the factors in the causation of some of the diseases, the micrococci and the bacilli, especially the former, the streptococcus pyogenes and staphylococcus pyogenes aureus, and also taking the stand that we suspect a *microbic origin in eczema, psoriasis,* pemphigus, etc. The requirement of a suitable soil for the developing of micro organisms was first mentioned and then the clinical difference in different cutaneous diseases which are produced by their surroundings and accidental causes was touched upon, and the boil and carbuncle were cited. These, it was stated, were due to the presence of the staphylococcus pyogenes aureus; that both have an active local inflammation of more or less intensity, resulting in the formation of a core, and that they both produce a systemic disturbance due to the auto-intoxication. It was also stated that the difference was caused by the different situations of the two lesions; that the carbuncle invaded tissue that was less elastic, that the exit of the pus was more difficult and that the fertile soil of patients suffering from diabetic and other trouble in which carbuncle was often found, made it more easy for the propagation of the micro-organism. He showed that micro-organisms were to be found around the invaded area of boils, and illustrated the same by citing a case in which, after the partial disappearance of a boil a second one appeared. The first one being one of considerable annoyance, both local and constitutional, to the patient; the doctor excised the second with the result that the local and constitutional trouble was cut short. The Doctor gave the history of some cases that came under his care in the Children's Free Hospital, in which on the parts subject to exposure to infection, as the hands, the face and the buttocks, there was found a condition of pustulo-crustaceous eruption, to which the Doctor was unable to give a categoric name. There was a number of pustules about the size of a split pea of irregular shape, raised above the surface and with a tense epidermic wall sometimes covered with a yellow, brown or blackish crust undermined by a purulent discharge, with a history of scratching, and upon examination pediculosis, scabies, and the other parasitic causes were eliminated. The Doctor came to the conclusion that this disease was due to infection with pus-producing cocci, usually staphylococcus pyogenes aureus or albus, and classed these cases with those suffering from pyodermia. Another class of diseases cited was among those admitted to the Children's Free Hospital, in which the skin lesion was so extensive as to make one believe that the trouble was some loathsome constitutional disease. The parts affected were the region of the genitalia and in the neighborhood of the uncombed hair, which is a mass of pustulo-crustaceous eruption. The skin is reddened, excoriated and infiltrated, which causes intense suffering to the little ones. Removal of the crust with soap and hot water and the application of antiseptic washes, destroyed the pus germs and at once brought about a change for the better. Another trouble is furnished by men who have been to some barber shop (probably the cleanliest) and who come, fearing they are suffering from barber's itch. Barber's itch or tinea sycosis is caused by the tricophyton. There is another variety of sycosis however, which somewhat resembles barber's itch, which is due to the invasion of pilo-sebaceous crypts with pus cocci. This variety does not present fully the picture of the tinea sycosis, though if it is neglected the hair follicles become sooner or later involved, especially in the region of the upper lip. The lesions are as a rule few in number and usually circular or oval in outline. There is some tumefaction and exudation covered with a very tenacious, brownish-yellow crust, beneath which is a purulent discharge. That pus organisms are present is proven by the fact that an antiseptic ointment applied after carefully removing the crusts, rapidly cures the disease. Very often this disease assumes the nature of a boil. The Doctor then enumerated some cases met with in his own practice, illustrating the different types of this disease, concluding with the advice that all cases should have careful attention in treatment after the recognition of their true nature with perseverance in the application of cleanliness, antisepticism and slight astringency.

PUBLIC HEALTH.

The Bubonic Plague, according to a dispatch of September 22, is again on the increase in Bombay Presidency, several Europeans having been attacked.

Division, Milk and Food Inspector, Weather Review for 1896 and Mortality Tables of the city.

Proceedings of the Connecticut Medical Society, 1897. Cloth, 385 pages. Published by the Society. 1897.

This is a complete report of the one hundred and fifth annual convention, held at Hartford, May 26 and 27, 1897. The papers on general medicine and obstetrics include papers relating to infantile diarrhea, tuberculosis, diphtheria, theories of immunity, "The Value of Correct Sitting as an Exercise for Invalids," and papers on Obstetric cases. The surgical papers are: "Essay on the Progress of Surgery," "The Treatment of Pus Cases in Operating for Appendicitis," "Laparotomy at the Hartford Hospital," "Report of Five Cases of Uterine Retrodisplacement Treated by Vaginal Fixation."

MISCELLANY.

Subjects announced for discussion at the fourth French Congress of Internal Medicine, to be held at Montpellier, April 12, 1898, are: 1. Clinical forms of pulmonary tuberculosis. 2. Associated bacterial and mixed infection. 3. Therapeutic application of organs with internal secretion.

The report of the Moscow Congress published in the Journal was selected and translated from the excellent report which appeared simultaneously and identical at first in all the leading foreign exchanges, furnished by the International Scientific and German Medical Press Associations.

Physicians in the Italian Legislature.—The *Gazzetta degli Osp. e delle Clin.* publishes the list of physicians who are members of the legislature, twenty-three in number, including three alienists of note and six professors, among them Professors Bacelli and Celli of Rome, Professor Bianchi of Naples and Professors Albertoni and Tizzoni of Bologna. Only four are mentioned as having retired from active practice.

New Million Dollar Hospital.—At Newcastle, England, Mr. John Hall has donated $500,000 to rebuild the Royal Infirmary and Mr. R. Lord, an ex-mayor of that city has been able to double the sum by his energy as a collector in the name of charity and of the Queen's diamond jubilee. The *Lancet* says of this generous hospital donation, that it is the greatest that has been made in the jubilee year outside of London. As the generous donor, Mr. Hall, has accompanied his gift with no onerous restrictions the governors of the infirmary are in a position to immediately accept it, and to soon give to Newcastle a modernized and magnificent structure.

A Worthy Medical Appointment in New York.—We take pleasure in noting the appointment of the veteran sanitarian, Dr. Stephen Smith, by Mayor Strong of New York City, to become a member of the important board of commissioners of charities and corrections, in succession of Mr. Silas Croft who recently was appointed to the surveyorship of the port of New York by President McKinley. This appointment of Dr. Smith is spoken of by the local press as being one of the best acts of the reform mayor, and this reason is given by one of the papers, namely, that Dr. Smith's services will be of especial value in helping the board to properly construct the buildings that have become necessary, and have been ordered to be built to relieve the enormous pressure that exists in nearly all the charitable and correctional institutions of the city

Maproni's method of enterostomy and enterorrhaphy as described in the *Gaz. degli Osp. e delle Clin.* of July 18 consists of an invagination of the intestines after the two stumps have been sutured together with a Czerny-Lembert suture. The inferior section is slipped into the superior for 5 or 10 mm., bringing the surfaces of the mucous membranes into contact, as also the serous. The triple thickness is then sutured through the two outside layers and partially through the inner, with double threads, each stitch 2 to 4 mm. long. A second row of stitches is taken parallel to the first, passing through the first two strata of the inferior portion of the intestine. The ends of the threads of the superior row of stitches are then tied two by two with the threads from the second row, which must be very close to the fold to prevent tearing out. This method is adapted to all cases of transverse section of the intestines and combines the advantages of the Murphy button and the Wölfler method, according to the inventor, who is surgeon to the Milan *Poliambulanza.*

The International Scientific Language.—Professor Sklifassowski proposed at the Moscow Congress the appointment of a committee of two delegates from each nationality represented, to decide the question of an international language, as the variety spoken is one of the chief drawbacks to international congresses. German preponderated at Moscow; even the delegate from Japan spoke in German when he expressed the hope that his country would be selected by the Congress for some future meeting. The number of important German universities in Germany, Austria and Switzerland must be borne in mind, as there is nominally only one French university. Even the *Progrès Médical* admits that more than one language is necessary, remarking that those who are unable to comprehend a paper or take part in a discussion in any one of the three principal languages on a technical subject with which they are perfectly familiar, had better stay at home.

Electrotherapeutics.—Recent communications emphasizing the importance of electricity in comparatively new fields are by Nedorodoff, in the treatment of extrauterine pregnancies, particularly when not over three months—"the only treatment when there are complications of hematosalpingitis or old periuterine hematoceles." Civera Lalse, in regard to treatment of diseases of the spine concludes: "Recovery can be obtained with it almost always when there is no osseous deformation, and when there is, electric treatment is a palliative of the greatest value" (Moscow Congress). Professor d'Arsonval's apparatus for "high frequency" and "undulatory" currents are recommended in high terms from several quarters. Apostoli has observed 518 patients treated, and calls the former "*the* treatment for the cell and general metabolism," while the latter is "an analgesic and congestion-relieving therapeutic measure in gynecologic cases of the highest order" (145 cases, including 108 gynecologic).—Report to Paris Acad. des Sciences, July 26.

Existence of a Nucleus in the Red Corpuscles and Anti-Coagulating Role of the Blood Plaques.—Professor Petrone of the University of Catania, Italy, has established the fact of the existence of the blood plaques in the blood as a normal morphologic element with the office of inhibiting coagulation. He also announces the existence of a nucleus in the adult red corpuscle in the blood of the higher mammals. His numerous experiments and tests, mostly with Lugol's solution, are described fully in the *Gaz. d. Osp. e d. Clin.* of July 25. The results authorize him to conclude that the fibrin ferment is not derived from the leucocytes, which are not a morphologic element proper of the blood, but from the red corpuscles. As they are destroyed this fibrin ferment, the so-called zymogen is liberated. The phenomena of coagulation therefore depend upon the action of the contained hemoglobin, the fibrin ferment on the fibrinogen while the blood plaques contain the coagulation-inhibiting substance.

Civilization and Syphilization explain the etiology of the present alarming increase in the cases of general paralysis, Krafft-Ebing asserted in the conclusion to his masterly presentation of progressive paralysis at the second general session of the Moscow Congress. While neurasthenia and progressive paralysis were scarcely known by name a hundred years ago, and until recently the average age was 40 years, now it is frequent and is observed even in the young. The increasing difficulty of the struggle for existence makes ruinous demands on the brain and general system, and stimulation is sought in excessive use of coffee, tea, alcohol, tobacco and excitements. The constantly greater prevalence of celibacy with the increasing difficulty of establishing a home at a suitable age, leads to the outside satisfaction of the sexual impulse, prostitution and syphilis. He considers the fact established by statistics that syphilis is the *sine qua non* of the disease, and that prophylactic measures against syphilis are the means to combat it.

The Brooklyn Maternity Institution.—At the Low Maternity of Brooklyn, in 1896, the number of patients was 109, mortality two. The school for nurses is maintained, but has not yet received an endowment of permanence. At the clinic for gynecology over two hundred new cases were treated. The interne staff, headed by Dr. MacLean, served in rotation, acting under the injunction to treat the patients with the same consideration that the latter would receive in a private house, and to "respect the feelings of modesty inherent in the sex." The writer of the report thinks that the amount of ophthalmia has been diminished by throwing over the Credé method, and says: "In the treatment of the eyes of the newly born infant we have for more than a year rejected the Credé method: the instillation of solution of nitrate of silver. Our experience since its rejection is that we have had fewer cases of ophthalmia, and those have been of less severity than we formerly had. At birth the eyes are carefully wiped out with a saturated solution of boracic acid, and this washing is repeated daily. In cases of severe ophthalmia the nitrate of silver is used occasionally, but in every case where it is used, the eyes are immediately afterward washed out with a solution of salt. Usually, a more frequent use of the solution of boracic acid, the increased secretion being removed as fast as it is poured out, is the only treatment required even in severe cases.

Increased Facilities for Laboratory Study at Jefferson Medical College.—The Board of Trustees of Jefferson Medical College has taken another forward step in adopting plans for instruction in the new laboratories of the college, and in making elaborate preparations for summer laboratory courses and for postgraduate teaching. The arrangements are that post graduate instruction in the various sub-departments of pathology shall be open to holders of medical degrees only; that undergraduate instruction shall be given between May 1 and October 1 of each year, such instruction to be credited on next year's work; and that any student or graduate of the college who may show special ability may be appointed by the professor of pathology to do prize work in the laboratories, or work which shall be honored by publication as original investigation. In this way, without at all impairing the efficiency or restricting the scope of its regular winter course, the Jefferson College establishes a complete system of summer laboratory work. The importance of this to young men, of whom there are many who wish to make the most of their time, and to equip themselves as quickly as possible for the practice of their chosen profession, is too obvious to need pointing out.

Hydrotherapy a Subject for Clinical Teaching.—The House of Parliament, Vienna, has taken up the subject of establishing a recognized educational clinic for the purpose of elucidating hydrotherapy. The proposer of the bill has so far succeeded in establishing his proposition that the representatives resolved a few months ago to appoint a special commission to inquire into the necessity and propriety of establishing such a school of education, and named Professor Albert as the chairman of the commission. The report briefly stated disapproved of any separate chair being established in the university. It discussed the various advantages and disadvantages of the treatment, stating that lectures are already given in Italian and German schools, while two of the Austrian medical faculties, Vienna and Innsbruck, provide ample instruction for the special treatment. Different doctrines of pathology and therapy are advanced in the elucidation of hydrotherapy that necessitate its connection with the present clinic. The treatment is nothing more than a special application similar to the serum treatment, electrotherapy, mechanical therapy, or massage, which might equally claim a separate chair in a university. The present schools have already sufficient assistants to teach this therapeutic method of treatment without further encumbering the chancellor of the university with new professorships.

The International Olympian Congress held at Havre in July included the delegates to the Olympian Games, representatives from educational and athletic institutions and organizations, etc. The resolutions adopted by the Congress advocated the harmonic union of gymnastics and athletic exercises as the aim of the renaissance of physical education. It considered that the development of games in educational institutions should be left to the initiative of the pupils; that the game should not be directed by the technical professors and that athletic associations should be freely organized and freely administered, under the benevolent eye of authority and the patronage of technical professors. It also advocated that the names of pupils who win distinction in both intellectual and athletic exercises should be published in the educational organs every year. Also that special cards recording the physical development should be sent to the parents twice a year. The establishment of a hydrotherapeutic service in every educational institution was demanded by the Congress and the game of tennis especially recommended for scholastic institutions. The professor of gymnastics should possess a certain knowledge of physiology, anatomy and hygiene and submit to written, oral and practical examinations before obtaining his diploma. The attention of the public authorities was called to the precarious pecuniary circumstances of most professors of gymnastics and the hope expressed of a change for the better. Further details will be found in the *Jour. d'Hygiène* of September 2.

Power of Township Trustee to Employ Physician.—A township trustee is, by Indiana law, made the overseer of the poor of his township. But the power to employ medical and surgical aid for the poor of a township or the county is vested in the board of county commissioners. Where there has been an exercise of that power, and suitable provision has been made, the appellate court of Indiana points out, in Board of Commissioners v. Galloway, June 2, 1897, it divests the township trustee of power to act, and he has no authority to employ medical aid for the poor of his township, unless the physician employed by the county abandons his contract, or refuses to perform it, or is at such a distance that his attendance can not be readily procured, or an emergency exists, or he lacks the skill and experience necessary to render reasonably efficient services in the case, and the dictates of humanity seem to require immediate action upon the part of the trustee. Even in these exceptional cases, a township trustee can only bind the county while he acts within the scope of his authority as the agent of the county. Where a trustee does not act within the scope of his statutory power, and where he has no authority to act at all, he can neither bind his township nor the county. And his agency is of such a character that the court holds all are bound to take notice of its scope and limitations.

Internal Causes of the Putrefaction of Cadavers (Med.-Leg. Congress.)—In case of a healthy person dying suddenly, microbes are only found on the surface of the body and in the large cavities communicating with the outer air, especially the alimentary canal, but in case of a diseased person the microbes may have already invaded the organs at the moment of death. In infective diseases such as cholera, putrefaction [illegible] during life; the emigration of the microbes into t[illegible] also have been started by intoxication from [illegible] etc. Bacteriology has furnished an explanation of the fact that an infant born dead putrefies like a piece of meat, while if the infant has lived a few hours the putrefactive processes start in the intestines. At birth the intestine is completely sterile, and it is possible by means of bacteriologic cultures to determine in certain cases by analyzing the intestinal flora, whether the corpse is that of a still-born infant or whether it had lived a few hours (from Malvoz' address). Descoust added that examination of the eyes showed that the cornea loses its transparency by the end of twenty-four hours, when important changes commence in the media of the eye. First they become turbid and then they ferment, when the eye protrudes from between the lids. It is at commencement of this period that the green spot appears in the right iliac fossa. Later the cornea is luxated by the progress of the putrefaction or there is a kind of resorption of the media. In both cases the organ collapses whether the humors have escaped or been absorbed. By this time it is the twentieth or twenty-second day in winter; the fifth or sixth in summer.—*Presse Med.*, August 25.

Bacteriology at the University of Virginia.—At the above-named university bacteriology is taught by lectures accompanied by practical work in the laboratory. The instruction given at the university in this subject differs from that given in most schools of medicine in several important respects. It is very commonly the case that the student is brought almost at the very outset into relation with the bacteria of disease, the whole or the larger part of the course of instruction being given to their specific study, the technique involved in their culture and determination and the specific products of their activity. These are all matters of the highest importance and should by no means be neglected, but exact and extensive knowledge of them may be and too often is associated with ignorance of the real nature and affinities of the bacteria, the general principles of vegetable physiology of which their characteristic activities constitute a special case, and of the essential conditions on which their culture depends. Believing that the educated physician should as far as possible know the scientific principles on which his professional knowledge rests, provision has been made for a short course which deals with the bacteria from the botanic standpoint, discussing the general morphology and physiology of plants to an extent sufficient to give the student an intelligent idea of the place of these organisms in the vegetable kingdom and of the relation of their life to that of other plants. This knowledge is made the basis of the farther discussion of their economic relations, their action as causes of disease and the methods resorted to for their manipulations, the most important processes of bacteriocultural technique being as far as possible fully illustrated and demonstrated in the laboratory.

Dr. Fuller, New England's First Physician.—Dr. E. E. Cornwall of Brooklyn contributed to the *New England Magazine*, February, a medico historic essay calling attention to the causes of the high mortality among the early settlers of Plymouth Bay. He states that there was an infectious element early at work as a destroyer of life, namely, that of pulmonary tuberculosis in the acute form of so-called "galloping consumption." This infection occurred among the Pilgrims in a degree almost epidemic, being conveyed "right and left" from one to another. Dr. Fuller was the first physician in New England, and a worthy representative of the medical profession. He lived in an age when medical science was in a very imperfect state, and the few glimpses we get of his methods of treatment do not indicate that he was at all in advance of his age, but he did the best he was able to do with the light he had, and died doing his duty in an epidemic. In personal character he stood very high. He was one of the pillars of the Pilgrim society. In 1633 an "infectious fevoure," thought by many to have been typhus fever, was brought to Plymouth, and twenty of the settlers there died of it, including three of the "Fathers," Peter Brown, Francis Eaton and Dr. Samuel Fuller. During the next thirty years eighteen more passed away, in the cases of only two of whom, Miles Standish and Edward Winslow, do we know the cause of death. The former died from vesical calculus and the latter of a fever, probably malarial, which he contracted in the West Indies. It was not till the end of the century, almost fourscore years after the landing on Plymouth Rock, that the last survivor, Mary Allerton, died at the age of 90.

Rules as to Skill and Pay Laid Down in Malpractice Case.—The correct rule, the supreme court of Iowa maintains, in the malpractice case of Whitesell v. Hill, is that a physician and surgeon when employed in his professional capacity is required to exercise that degree of knowledge, skill and care which physicians and surgeons practicing in similar localities ordinarily possess. It however does not consider that any harm was done in this instance by charging the jury that as some authorities hold, the degree of proficiency, skill and care required was that ordinarily possessed by members of the profession in the vicinity where the defendant practiced, inasmuch as the evidence showed that there were several educated and experienced physicians and surgeons there. The contention, which there are also some authorities tending to support, that a valid claim for services rendered by a physician, and one for damages sustained by the patient in consequence of malpractice, can not co-exist, the court holds is not in accord with the law and practice in Iowa. It says that the right of one party to a contract but partly performed by him to recover the value of the services he has rendered, is subject to the right of the other party to a proper allowance for damages he may have sustained without fault on his part for the failure of the party seeking to recover to fulfill the agreement on his part. And it declares that it does not know of any sufficient reason for not applying these rules to the contract between a physician and his patient. It says that a physician may render service which in the main is all that is required of him, but he may have been negligent in some particulars to the injury of his patient, and in such a case a proper allowance for the injury should be made. Likewise, if the physician's treatment is so unskilful or negligent that the injury exceeds the value of his services, he should be permitted to show the value of the services, to reduce the amount for which he is liable. And this is true whether the action against him for malpractice is regarded as founded upon contract or tort.

Progress in the Treatment of Rinderpest.—The inoculation method of Professor Koch has advanced sufficiently in its practical testing to enable experts to begin to criticise its value and to ascertain what are its disadvantages. It appears that the use of fresh bile has not been without disaster, for some cattle inoculated by Dr. Kohlstock have shown an enormous mortality, over 80 having died out of a fine clean herd of 149 very valuable cattle. In the case of clean herds, generally speaking, fairly good results are obtained, although it is reported that no herd has yet been inoculated with bile in which rinderpest has not followed. The greatest difficulty is the fact that the bile does not keep, and that, according to Dr. Koch, only green biles can be used. But green biles are only obtained rarely, the most frequent proportion being one in seven. As only fifty animals can, on the average, be inoculated from the bile of one animal, it follows that one rinderpest animal is required even under the best conditions to inoculate seven animals. It is reported that Dr. Edington states that the addition of a certain proportion of glycerin to fresh bile succeeds in preserving it without interfering with its immunizing property. The same experimenter finds that the blood of cattle taken during the latter stages of the malady, if prevented from coagulation by citrate of potash and then preserved by glycerin, has also very considerable immunizing power, but blood virus, like blood serum, appears to be a little uncertain in its action, and all samples do not show equal results. If the discovery of Dr. Edington is correct, that glycerin can be used, and that under such circumstances galls other than green are useful, this will probably be found the best method to adopt, provided always that the bile inoculation is followed up by virulent blood during the period that the temporary immunity holds.—*British Medical Journal.*

The Moscow Congress was one of the most important ever held on account of the scientific activity displayed (over 1,000 communications were received), although it was not marked by any epoch-making discovery. The attendance was fully 10,000 including the ladies and children. A Russian exchange mentions with interest a family from New York in which the father, mother, two sons, daughter and son-in-law, were all physicians and inscribed members of the Congress. The weather was extremely warm all the while. All speak of the cordial hospitality of the Russians with enthusiastic gratitude. Paris was selected as the seat of the next Congress, in 1900, with Professor Lannelongue, President, and Chauffard, General Secretary. The triennial international prize of 5,000 francs founded by the city of Moscow, to be awarded at each International Medical Congress, as already mentioned in the JOURNAL, page 298, was presented to Henry Dunant, the founder of the Red Cross, who has spent his life and his fortune in the relief of suffering humanity. He is also suggested as the possible recipient of one of the five large prizes to be awarded annually, according to the will of the Swedish dynamite multimillionaire, Alfred Nobel (*vide* JOURNAL, Vol. xxviii, page 330).

Medical Practice Among the Mongols.—According to the *Medical Press and Circular*, a very prevalent affection among the Mongols is the itch, due in a large degree to their repugnance to the washing of either their persons or garments. In their tents they live so closely together that if one of them gets the itch all soon have it. Various other skin diseases are prevalent among them. Rheumatism is often of frequent occurrence and the remedy largely used for that trouble consists of kneading or a kind of massage; they make use of a "rheumatism stick," a piece of wood so bent that any part of the body can be reached by the patients in their self application of the kneading process. A peculiar disease called "narry," due to their indulgence in their native spirituous liquor, is frequent; the stomach becoming intolerant of food so that the patient ultimately dies of starvation. The treatment of the sick and injured rests chiefly with the priests or Buddhist lamas, whose system is quite elaborate, but based for the most part on superstition. Instead of paying occasional visits to the patient, their method is to reside in his house until recovery or death takes place, or the case is decided to be incurable. The people have great confidence in drugs and medical regimen, including the water-cure, the latter object causing them to resort to springs, both hot and cold, that are somewhat abundant in Mongolia and Northern China. They place implicit confidence in the medical knowledge of the foreign missionaries who visit their inhospitable country, but express wonder and astonishment when their proffered recompense is refused by the latter. For the bite of a dog they apply to the wound a portion of the fur of the animal; literally "the hair of the dog" is their remedy. They use the loadstone in powdered form as a cure for ulcers, deafness, etc. They attribute many diseases to the influence of the planets and constellations, to offenses committed and to fate. Hygiene or preventive measures do not enter much into their scheme of treatment.

Realizing Upon Life Insurance.—A legal friend of ours believes that he knows of at least one case where a well-insured man, suicidally inclined, has been able to dupe both the insurance company and the coroner's jury. This man, aged under 50 years, had been greatly worried over losses in business, and set to work in the most methodic way to take his own life in such a way that the fact of suicide might never be known. In his third attempt he succeeded in taking a lethal dose of a prepation of morphin, and so prepared the circumstantial evidence that was to come under the notice of the coroner, that the latter assented to a verdict of death by heart disease. In a previous effort he had failed to take a dose sufficiently large to cause death, but had laid his plans to a nicety for the purpose of "realizing on his life insurance" for the benefit of dear and dependent members of his family. He first set about to give himself an attack of indigestive diarrhea by making a meal of cheese, lobster, ice-cream, etc., and so far succeeded, that he had an excuse for having an antidiarrheal mixture and a strong morphin preparation in two bottles, almost identical in appearance, and kept by him side by side on his medicine shelf, his intention being to so dose himself with the latter preparation that he would be found dead in his bed in the morning, and the inquest would be led to decide that an accidental overdose was the *causa mortis*; but this attempt failed, because his dose was too small for his object. A further effort, and second failure was one in which he wilfully exposed himself to a pneumonia in midwinter weather; he first, by violent exercise get himself into profuse perspiration, and then removing all his clothing, placed himself before an open window courting the icy blasts of nearly zero weather. But he could not "realize" in that manner. His third attempt succeeded, as said before, and his ante-mortem conduct and arrangements appear to have been so complete as to have side-tracked the inquest and to have humbugged the officers of the law into accepting a certificate of death from heart disease, without a verification by autopsy. It is surmised by our informant that this form of accident is not an infrequent occurrence among despondent men who have been carrying heavy life insurance. We believe that there are not a few who, at certain periods of their lives, think less of their own lives than they do of the comfort of their families, and are ready to undertake to realize on their life insurance for the benefit of the latter.

The Successful Treatment of a Wound of the Heart.—Dr. Rehn, of Frankfort, at the Congress of the German Surgical Association, held in April last, read a paper on wounds of the heart and their treatment. After pointing out that penetrating wounds of the heart are rare, and that large lesions cause immediate death while small ones may heal, he went on to state that auricular wounds are more dangerous than ventricular owing to the thinness of the auricular wall. Hemorrhage, however, is apt to be more profuse when the right ventricle is damaged, and the prognosis in any case depends practically upon the quantity of hemorrhage. The diagnosis of the site of lesion is difficult to make, but in doubtful cases cautious probing must be performed. The main indication of treatment, Dr. Rehn said, was to keep the patient as quiet as possible, but severe dyspnea generally precludes this. Venesection has been recommended to check the hemorrhage. To remove the blood from the pericardial it has been recommended to puncture the pericardium; but as there is risk of inflicting a new lesion it is better to make a long incision and discover the seat of the lesion. Italian surgeons were the first to suggest sutures in these cases, and Professor Rehn has lately been so fortunate as to meet with a case of wound of the heart where by suturing he was able to save his patient. A young man was brought to hospital, having received an injury from a knife in the left side of the chest. There was much dyspnea and hemorrhage. As the pericardium became diluted the patient's state became worse and worse. The wound in the fourth intercostal space was then opened up, and after resection of the fifth rib the pericardium was incised. A wound one and a half centimeters in length was then found in the right ventricle. This Dr. Rehn closed by three sutures and packed the pericardial cavity with iodoform gauze. After the operation the pulse and respiration immediately improved, and although the patient's convalescence was retarded by suppurative pleuritis he made in the end a complete recovery.

Detroit.

THE WAYNE COUNTY MEDICAL SOCIETY held a very interesting meeting Thursday evening, September 23. The paper of the evening was on the subject of "Croup," read by Dr. B. R. Shurly, dealing particularly with diphtheric croup both as a primary disease and as secondary to involvement of the pharynx. He laid down the principle that all cases of croup in which there is a gradual increase in the dyspnea with cyanosis, etc., diagnosis of diphtheria should be made, so that the physician and patient may be on the safe side; and all children between the ages of 1 and 6 years in the same household should be immunized. The treatment in these cases is antitoxin combined with intubation. In the old treatment of these cases combined with intubation, the death rate is about $66\frac{2}{3}$ per cent.; with the antitoxin and intubation method the death rate has been reduced to $33\frac{1}{3}$ per cent., and in his own cases to 28 per cent. Out of ninety cases treated by him with intubation there were twenty-six deaths. In the discussion the President brought up the question of paralysis following diphtheria, and stated that it was remarkable how often cases of true diphtheric laryngeal inflammation had been overlooked as cases of diphtheria and treated for simple tonsillitis. He stated that he had frequently seen patients suffering from paralysis of accommodation of the eye, who had denied ever having diphtheria but who had admitted having had tonsillitis. In his opinion, paralysis never occurred after primary laryngeal diphtheria. In reply the author of the paper said that he believed the reason why paralysis never followed laryngeal diphtheria was because of the fact that the larynx was particularly impervious to the toxins of diphtheria, illustrated by the fact that primary laryngeal diphtheria, when not of the ascending or descending variety, does not produce septic features.

TELEPHONE COMPANIES.—Owing to the fact that there are two telephone companies in Detroit the druggists and physicians have determined to organize for the sake of minimizing the evil thus arising, and committees have been appointed from the different medical societies of Detroit and from the organized druggists to confer for the purpose of arranging some plan of action whereby the telephone nuisance may be abated.

THE HEALTH OFFICE REPORT for the week ending September 26 shows 90 deaths in the city, of which 40 were children under 5 years of age; births 86, of which 43 were males. There are at present 16 cases of diphtheria and 28 cases of scarlet fever. Three deaths were caused by diphtheria and 2 by scarlet fever.

Societies.

American Association for the Study and Cure of Inebriates.—The annual meeting will be held at New York City, October 22.

The American Public Health Association will hold its annual meeting in Philadelphia, Pa., October 26 to 29.

The Vermont State Medical Society will meet at St. Albans, Vt., October 15 and 16.

The following meetings were recently held:

District of Columbia.—National Society of Electro-Therapeutists, Washington, September 29 and 30.

Illinois.—Illinois Army and Navy Medical Association, Springfield, September 29. The following officers were elected: President, Dr. A. C. Corr, Carlinville: first vice president, Dr. P. L. Dieffenbach, Havana; second vice-president, Dr. W. O. Ensign, Rutland; third vice president, Dr. O. B. Ormsby, Murphysboro; fourth vice-president, Dr. D. H. Law, Dixon; secretary and treasurer, Dr. E. R. Bartlett, Springfield. Chicago Medical Society, Chicago, September 29.

Maryland.—Baltimore County Medical Association, Baltimore, September 23.

Minnesota.—Ramsey County Medical Society, St. Paul, September 27.

Ohio.—Cleveland Medical Society, September 24. Mansfield Academy of Medicine, September 28.

Pennsylvania.—American Electro-Therapeutic Association, Harrisburg, September 22 and 23.

Tennessee..—Marshall County Medical Society, Lewisburg, September 21. East Tennessee Medical Society, Knoxville, September 30 and Octocer 1.

CHANGE OF ADDRESS.

Berens, Bernard, from 2002 to 2041 Chestnut St., Philadelphia, Pa.
Butler, F. A., from 210½ Clark St., to Ill.
Brown, E. V. L., from Morrison, Ill., t ago, Ill.
Ewing, W. Brown, from Wernersvill
Houston, J. M., from San Francisco to Falls City, Neb.
Kaull, Wm. A., from Princeton to Ohio, Ill.
Kuhlman, C. G., from 935 Market St. to 123 Ellis St., San Francisco, Cal.
Knopf, S. A., New York, N. Y., address is 955 instead of 935 Madison Av., as published in September 25 issue.
Logan, J. E., from 306 Keith & Perry Bldg. to 1208 Wyandotte St., Kansas City, Mo.
Le Grand, J. C., from Annison to Birmingham, Ala.
McDermith, S. F., from 1702 Champa St. to 503 Mach Block, Denver, Colo.
Morrow, J. C., Scio, Ohio, to 337 Jacunda St., Pittsburg, S. S., Pa.
Moore, J. Wm., from Detroit to Atlantic Mine, Mich.
Mattison, F. C. E., from 4936 Vincennes Av. to 4458 Cottage Grove Av., Chicago, Ill.
Reed, B., from Atlantic Mine, N. J., to 4726 Kingsessing Av., Philadelphia, Pa.
Rogers, A. S., from Vassar to Ann Arbor, Mich.
Tudor, Mary S., from South Windsor, to 179 Sigourney St., Hartford, Conn.
Tombaugh, L. H., from Washington, Pa., to Three Rivers, Mich.
Van Eman, J. H., 1003 E. 14th St. to 1326 Forest Av., Kansas City, Mo.
Wagely, T. J., from Paris, France, to Cleburne, Texas.

LETTERS RECEIVED.

Bauer, L. D., Philadelphia, Pa.; Boehringer, C. F., & Soehne, New York, N. Y.; Barlow, E. B., Toledo, Ohio.
Chamberlain, G. L., Newberry, Mich.
Fleming, Ellis, Woodland, Iowa; Fisk, Samuel A., Denver, Colo.
Gaut, S. G., Kansas City, Mo.
Knopf, S. A., New York, N. Y.
Hummel, A. L., Advertising Agency, New York, N. Y.
Le Count, E. R., Chicago, Ill.
McCormick, Henry C., Williamsport, Pa.; McCorn, W. A., Kankakee, Ill.; Mathews, J. M., Louisville, Ky.
Pallak, S., St. Louis, Mo.; Peacock Chemical Co., St. Louis, Mo.; Paquin, Paul, St. Louis, Mo.; Porter, John L., Chicago, Ill.
Ridlon, John, Chicago, Ill.; Rowley, W. S., Chicago, Ill.
Sothoron, Elmer, Washington, D. C.
Vansant, E. L., Philadelphia, Pa.
Weaver, W. H., Chicago, Ill.; Williams, E. J., Windsor Mills, Quebec; Wingate, U. O. B., Milwaukee, Wis.; Walker, Jason, Minot, Me.; Williams, C. L., Conneaut Lake, Pa.

THE PUBLIC SERVICE.

Army Changes. Official List of Changes in the Stations and duties of officers serving in the Medical Department, U. S. Army, from September 25 to October 1, 1897.

First Lieut. William F. Lewis, Asst. Surgeon, the order directing him to report for duty at Ft. McPherson, Ga., is amended so as to direct him to report for duty at the new post on Sullivan's Island, S. C.

Capts. Charles Richard and George McCreery, Asst. Surgeons, ordered to report Oct. 4, 1897, to the president of the examining board appointed to meet at the Surgeon General's office, Washington, D. C., for examination for promotion.

Col. Charles R. Greenleaf, Asst. Surgeon-General, will in addition to his present duties in charge of the medical supply depot in San Francisco, Cal., take charge of the office of the chief surgeon, Dept. of California, during the absence on leave of the chief surgeon.

Capt. Robert J. Gibson, Asst. Surgeon (Ft. Thomas, Ky.), is ordered to report to the president of the examining board at Surgeon-General's office, Washington, D. C., Oct. 4, 1897, for examination for promotion.

First Lieut. Henry R. Stiles, Asst. Surgeon, Ft. Preble, Maine, ordered to report to the president of examining board at Washington, D. C., Oct. 18, 1897, for examination for promotion.

Major Charles B Byrne, Surgeon, is relieved from duty at Ft. Snelling, Minn., and ordered to Plattsburg Bks., N. Y., for duty.

Major Philip F. Harvey, Surgeon, on being relieved from duty at Plattsburg Bks., N. Y., is ordered to Ft. Snelling, Minn., for duty.

Capt. Jefferson D. Poindexter, Asst. Surgeon, now at Willetts Point, is ordered to temporary duty as attending surgeon and examiner of recruits in New York City, relieving Capt. Charles Richard, Asst. Surgeon, who is ordered to Ft. Monroe, Va., for duty.

A board of officers to consist of Lieut.-Col. Alfred A. Woodhull, Deputy Surgeon General; Major Curtis E. Munn, Surgeon; Capt. William F. Lippitt, Jr., Asst. Surgeon, is appointed to meet at Hdqrs. Dept. of the Colorado, Denver, Colo., Monday, Oct. 18, 1897, for the examination of medical officers for promotion.

First Lieut. Harry M. Hallock, Asst. Surgeon, will report to the president of the examining board at Denver, Colo., Oct. 18, 1897, for examination for promotion.

A board of officers to consist of Col. Charles R. Greenleaf, Asst. Surgeon-General; Major Edward R. Moseley, Surgeon; Capt. Euclid B. Frick, Asst. Surgeon, is appointed to meet at Hdqrs. Dept. of California, San Francisco, Cal., on Monday, Oct 25, 1897, for examination for promotion of officers of the Medical Department.

Capt. Paul F. Straub, Asst. Surgeon (Angel Island, Cal.), ordered to report to the president of the examining board, San Francisco, Cal., Oct. 25, 1897, for examination for promotion.

A board of officers to consist of Lieut.-Col. Henry R. Tilton, Deputy Surgeon General; Capt. William C. Borden, Asst. Surgeon; Capt. Henry A. Shaw, Asst. Surgeon, is appointed to meet at Hdqrs. Dept. of Dakota, St. Paul, Minn., on Monday, Oct. 18, 1897, for examination of medical officers for promotion.

First Lieut. George J. Newgarden, Asst. Surgeon, ordered to report to the president of examining board, St. Paul, Minn., Oct. 18, 1897, for examination for promotion.

The Journal of the

American Medical Association

Vol. XXIX. CHICAGO, ILL., OCTOBER 16, 1897. No. 16.

ADDRESS.

THE RISE AND PROGRESS OF DERMATOLOGY.

An address delivered at the opening of the Section of Dermatology, at the Sixty-fifth Annual Meeting of the British Medical Association, Montreal, Aug. 31 to Sept. 4, 1897.

BY MALCOLM MORRIS, F.R.C.S. Edin.

PRESIDENT OF THE SECTION; SURGEON TO THE SKIN DEPARTMENT, ST. MARY'S HOSPITAL, LONDON.

[Abstract from advance sheets of the British Medical Journal.]

As embryology furnishes the key to the riddles of anatomy, so the history of the evolution of any branch of science throws light on many points that would otherwise be dark, explains the origin of terms and theories, rescues from oblivion truths overlooked or forgotten, and, showing the pitfalls which hindered those who have gone before, teaches us to walk more warily.

Dermatology, although its victories have perhaps been less showy than those won in some other special departments, has not lagged behind in the onward march of medicine. The centenary of the birth of scientific dermatology is not long past. In 1790 the Medical Society of London awarded the Fothergillian gold medal to Robert Willan, who had some time before submitted to it the outline of his plan for the arrangement and description of cutaneous diseases. Willan may justly be called the creator of dermatology. Before him the skin was looked upon more as a mirror on whose face internal disease "glassed itself in tempest" than as an important organ subject to manifold disorders peculiar to itself.

Forerunners of Willan.—Willan was not the first who wrote on skin disease. As our terminology bears witness, the Greeks gave a good deal of attention to the subject. Hippocrates speaks of "pityriasis," "lichen," "herpes," "pomphi," and many other forms of cutaneous lesion, and roughly classifies them. Later Celsus, Galen, Paul of Ægina, and after them the Arabians, described various affections of the integument. The medieval writers saw much of leprosy, and they doubtless often imagined it where it did not exist. At a later period syphilis overshadowed everything.

The first treatise professedly devoted to diseases of the skin was that of Hieronymous Mercurialis of Venice, "De Morbis Cutaneis et de Omnibus Corporis Excrementis." The author had, however, nothing to teach beyond what he found in the ancient writers. In the early part of the eighteenth century Daniel Turner produced "A Treatise of Diseases Incident to the Skin," which is almost wholly a compilation from other writers, and treats not of the skin alone, but of all "distempers" affecting "the outward parts or confines, as may be said, of the human body." Thus not only the eruptive fevers, the "green sickness" and the "yellow jaundice," but phimosis and paraphimosis, hemorrhoids, "chaps on the fundament," imperforate conditions of the natural passages of the body, ulcerations of all kinds, burns, stings and bites of venomous creatures, hydrophobia and poisoned wounds, are looked upon by the author as falling within his province.

Later in the same century there appeared almost simultaneously two works, each of which in its own way marked a distinct advance towards a scientific dermatology. In a book entitled "Doctrina de Morbis Cutaneis," Vienna, 1776, Joseph Jacob von Plenck for the first time attempted a complete classification of diseases of the skin. He arranged them according to what appeared to him to be the most characteristic objective features, in 14 groups with 120 varieties. In his "Tractatus de Morbis Cutaneis," Paris, 1777, Lorry, besides giving good descriptions of clinical phenomena, discussed the pathology of cutaneous affections in the light of the knowledge of the structure of the skin and the morbid processes of which it might be the seat, that existed in his day.

Neither Plenck nor Lorry, meritorious as were their works, did much to dissipate the darkness that was upon the face of this branch of medicine. At the beginning of the nineteenth century it could be said with perfect truth that little improvement had been made in the subject at large since the days of Avicenna.

The birth of dermatology.—In 1808 there appeared the first volume of Willan's treatise "On Cutaneous Diseases," a great work which its author did not live to complete. Ten years before, he had given to the world a slender volume dealing with a particular class of lesions of the skin. Willan set himself the task of reducing the chaos of skin diseases to something like a cosmos. The following are, in his own words, the objects at which he aimed in the execution of this design:

1. To fix the sense of the terms employed by proper definitions.
2. To constitute general divisions or orders of the diseases from leading and peculiar circumstances in their appearance; to arrange them into distinct genera and to describe at large their specific forms or varieties.
3. To classify and give names to such as have not been hitherto sufficiently distinguished.
4. To specify the mode of treatment for each disease.

Like Plenck, Willan grouped skin diseases according to the character of the predominent lesion; and indeed there can be little doubt that he took the groundwork of his classification from Plenck. The English dermatologist, however, reduced the fourteen orders of his Austrian forerunner to seven. To these another order, "bullæ," was afterward added. This classification is of course very defective, inasmuch as it takes account only of the outward and visible signs and results of disordered action. As has but a limited range of pathologic expression, lesions identical in appearance and in structure are produced by widely different causes. Hence a classification based solely on objective appearances inevitably led to the formation of motley groups including conditions having no essential feature in common. But Willan's classification, defective as it was, at least introduced a definite principle of arrangement into a region of pathology where before all was "most admired disorder." If he got the idea from Plenck, he must be allowed the credit of having greatly bettered the instruction which he received, and of having presented it to the medical world in such a manner as to impress on the mind of the profession.

It is not, however, Willan's classification that constitutes his chief title to be regarded as the founder of dermatology. His judicious selection and accurate definition of terms; his astonishingly faithful word pictures of the appearances of disease drawn directly from nature, and made more vivid but scarcely more graphic by the colored engravings with which he supplemented his descriptions, and his rational methods of treatment, were all his own. It was his teaching that transformed a confused jumble of folklore as to "tetters," wet and dry, and of figments of the medical imagination embodied in words of learned sound but little meaning into a science, rudimentary indeed, but grounded on a solid foundation of observed fact.

The English school.—Willan left behind a disciple well worthy to wear his mantle. Thomas Bateman, who completed Willan's unfinished "Delineations of Cutaneous Diseases," published a "Practical Synopsis of Cutaneous Diseases," which did far more to make his master's work known than Willan's own unwieldy and incomplete book. It is hardly too much to say that without Bateman Willan might have been forgotten. Bateman, however, was not a mere expositor; he was a man of truly scientific mind, and would doubtless have added largely to knowledge had not he, too, been cut off prematurely.

Bateman's "Synopsis" ran through several editions in his lifetime, and afterward found an editor in Anthony Todd Thomson, who also published an "Atlas of Delineations of Cutaneous Eruptions," illustrative of the descriptions in Bateman's book. Thomson paid special attention to diseases of the skin for more than thirty years. He was an accurate observer and was very successful in treatment. Toward the end of his life he embodied the fruits of his experience in a "Practical Treatise on Diseases Affecting the Skin," which was completed by his nephew, Edmund Alexander Parkes, and published in 1850. Thomson held that there could "scarcely be any difference of opinion respecting the necessity of arranging the tribe of those diseases. . . . (of the skin) according to the physical characters of the eruptions," and in adopting this method he chose "as the least exceptionable the order of Willan." Thomson was physician to University College Hospital, where he was the first of what may be termed the dermatologic succession, which, handed on in turn by Parkes, Hillier and Tilbury Fox, is still worthily continued by Radcliffe Crocker.

Almost simultaneously with the treatise of Thomson and Parkes there appeared a work which is one of the landmarks in the history of the English school of dermatology. This was Erasmus Wilson's "Diseases of the Skin," the preface to which is dated 1851. Wilson, who had commenced his scientific career as an anatomist, had already done a good deal of work in dermatology, particularly in the microscopic study of the cutaneous tissues. He made a new classification of skin affections, grouping them according to the structure in which the morbid process originated into four primary divisions. 1, diseases of the derma; 2, diseases of the sudoriparous glands; 3, diseases of the sebiparous glands; 4, diseases of the hair and hair follicles. Wilson's influence was for a long time predominant among his own countrymen, and by workers in other countries he was looked upon as the foremost representative of British dermatology. He had an eye for form and color and often found the right word to express them. His description of the diseased conditions are thus almost unrivaled in their picturesque and yet faithful rendering of appearances. He added little, however, to our knowledge of the pathology and therapeutics of skin diseases, and added not a little to the confusion which existed on the subject by his artificial classification and his ever-changing nomenclature.

The living leader of our British school of dermatology, Mr. Jonathan Hutchinson, has brought to the study of the pathology of the skin a knowledge of disease in general such as probably no other dermatologist has ever possessed. This, together with a marked originality and independence of mind, and a singular power of seeing points of likeness in things to outward seeming most unlike, has enabled him to throw an unexpected light on many dark places of dermatology. The characteristics of the British school of dermatology are those commonly held to be distinctive of the British intellect in whatever sphere it is set to work. We are a practical people, loving facts and caring little for theories. Accordingly British dermatologists from Willan to Hutchinson have been, first of all, observers. They have striven to get at what Majendie called the *fait brut*, to see things as they really are, and to describe what they saw as faithfully as they could. They have been distrustful of generalizations and cautious, perhaps over-cautious, in deductions. But the facts gathered by them have endured while theories and systems have followed each other into nothingness; and dermatology as it exists today is largely the work of their hands.

The French school.—In France a school of dermatology arose independently in the early years of the century. In 1808 Alibert published his "Description des Maladies de la Peau observées à l'Hôpital Saint Louis," which he followed up two years later by a "Traité Théorique et Pratique des Maladies de la Peau" and several other works. The most valuable part of his publications was the illustrations; his writings only added to the darkness in which the whole subject of diseases of the skin was then enshrouded. His terminology was to the last degree confusing, his classifications arbitrary, his descriptions often fanciful. Yet he contributed to the advance of knowledge by directing the attention of more scientifically minded workers to the subject. Among these was Biett, who adopted Willan's classification with some modifications and introduced it into France. In 1831 Rayer sketched out a plan of classification of skin diseases on a basis of morbid anatomy, dividing them into: 1, inflammations; 2, morbid secretions; 3, congestions and hemorrhages; 4, anemias; 5, neuroses; 6, deformities. Among the leaders of the French school who followed Biett were Cazenave, Gibert, Devergie and Bazin, all of whom did something to advance the knowledge of skin diseases, although they were apt to let themselves be misled by a tendency to erect systems on unsound foundations. In recent years the labors of Hardy, Vidal, Besnier and Brocq have placed the French school in the forefront of scientific dermatology, a position which, with such men as Darier, Thibierge, Wickham to take the place of their seniors when they have to fall out of the ranks, it is in no danger of losing.

The German school.—The year 1844 marked the beginning of a new era in the study of disease of the skin, for it witnessed the first appearance before the scientific world of Ferdinand Hebra. That remarkable man breathed a new life into the dry bones of dermatology, and set it on a path of progress which has already led to great results. Hebra applied to the investigation of skin diseases the pathologic teaching of Rokitansky. He classified them not according to their objective appearances or to the structures supposed to be primarily or mainly affected, but according to the nature of the pathologic processes of which they were examples. He used the experimental method, producing various lesions on healthy skin by artificial means, and observing the changes which they underwent when allowed to run their own course and when modified by treatment of different kinds. In this way Hebra rationalized dermatology, ridding it of the superstitions as to dyscrasiæ with which it had before been infested and giving to the treatment of skin disease a directness of purpose and a simplicity of means undreamed of by his predecessors. The influence of his teaching was felt everywhere except in France, where the traditional belief in dyscrasiæ persisted till a comparatively recent period. Hebra's work has been carried on by Auspitz, Kaposi and Neumann in Vienna, by Pick in Prague, Schwimmer in Buda-Pesth, Lewin and Lassar in Berlin, Neisser in Breslau, and others.

If Willan was the creator, Hebra must be acknowledged as the greatest among the reformers of dermatology. This glory must be his in spite of the fact that his classification in its leading features had been anticipated by Rayer. Hebra, however, worked it out so fully as to make it his own; and his classification, though it has necessarily been modified as knowledge grew, notably by the influence of Virchow's "cellular pathology" and by the newer bacteriologic doctrine, can never be superseded till an arrangement based on etiology becomes possible.

The American school.—The history of dermatology in America has been written by Prof. J. C. White of Harvard and by Prof. Louis A. Duhring of Philadelphia, from whom all that here can be said on the subject is taken. For the first thirty years or more of the century little or no interest was taken in cutaneous affections in America. In fact, as Duhring tells us, a disposition existed to consign the whole of this branch of medicine to those outside the professional pale. No one seemed prepared to take up the matter. In 1845 appeared the first American work on dermatology, "A Synopsis of the Symptoms, Diagnosis and Treatment of the more Common and Important Diseases of the Skin," by N. Worcester, Professor of Physical Diagnosis and General Pathology in the Medical School of Cleveland. The book is described by Duhring as being little more than a compilation from the works of the French and English dermatologists of the day. In 1836 an infirmary for diseases of the skin was opened in New York, being the first institution of the kind established in the United States, and lectures on skin diseases were delivered there and afterward in some of the medical schools of New York between the years 1837 and 1854 by Dr. H. D. Bulkley, father of Dr. L. D. Bulkley, whose name is well known to all dermatologists.

At this time Paris was the center of the dermatologic world, and American students accordingly went there for instruction in the subject. Hence for many years American dermatology was the direct offspring of the French school, the influence of which was only slightly tempered by reprints of the works of Wilson and other English writers. At a later period Americans flocked to Vienna, and on returning home spread the doctrines of Hebra among their countrymen. As early as 1859 Hebra's teaching was made known in America by Prof. James C. White, who two years later gave the first course of lectures on diseases of the skin at Harvard. After the Civil War clinical lectureships on the subject were established in several important schools. In 1870 the foundation of the *American Journal of Syphilography and Dermatology* did something to promote the advancement of the knowledge of skin diseases in America, and the establishment of the American Dermatological Association in 1877 gave a powerful impulse in the same direction, which was further aided by the creation of the *Archives of Dermatology*. Yet in 1871 Professor White complained that as yet America had contributed little to dermatology, and that this branch of medicine had hardly then found a place among his countrymen as an acknowledged specialty. Now this reproach has been wiped away, and American dermatology represented by Duhring, White, Bulkley and others, is recognized as being in the van of progress.

The fusion of the schools.—Each of the three great schools which helped to lay the foundations of modern dermatology had certain marked characteristics. The English was essentially clinical, using classification only as a practical help in diagnosis. As observed, the French systematized, striding somewhat impatiently over facts to get at general formulas, which though plausible on paper, too often broke down in application. The German was pathologic, giving attention mainly to the mechanism and occasionally taking too little heed of the causes setting it in motion. Much of what was good in each still survived in the cutaneous medicine of the present day.

Now dermatology is truly international, the different schools which were formerly as separate states having become fused into one scientific commonwealth. This has been accomplished by the translation of representative works of each school into the language of the others; by the multiplication of journals devoted to this special branch of medical science in which everything of value that is published in any part of the world is gathered up and summarized; by the facilities of communication which make it easy for the scientific pilgrim to visit every dermatologic shrine where his devotion is likely to be rewarded with knowledge of some new thing; and by congresses, those marts for the exchange of scientific wares which have so powerfully aided in the diffusion of knowledge in the extinction of national jealousies and in the correction of provincial ways of thought.

A man trained in a particular school is apt to be narrow if he knows nothing of any other. In dermatology this kind of narrowness was especially exemplified in the French school, but neither of the others was entirely free from it. How slowly the work of even so brilliant a dermatologist as Hebra became known to the profession in other countries at a time comparatively recent is shown by the following passage from Professor White. Speaking of the middle of the fifties he says: "It was not until the intelligence began to spread, slowly borne by word of mouth from country to country, that in an Imperial city of Austria there was a man teaching skin diseases as they had never been taught before, with unlimited means of clinical illustration, with the keenest eye for observation, with an unbounded amount of information drawn from many years of experience, with a self-restraint which no desire for premature fame could tempt into hasty publication, and with a sound and logical mind, that the German school of dermatology some fifteen years ago began to be known and to advance to that pre-eminent position it now holds." Fame flies faster nowadays, but the very ease and rapidity with which the results of a man's work can be made known now lead to the publication of much that is inaccurate observation and immature speculation.

Progress in knowledge.—The most striking feature on the dermatology of today as compared with that of the beginning of the century is the knowledge of the nature and causes of skin diseases that has been gained. Willan and Bateman left little in the way of outward appearances for those who came after them to describe, but no real knowledge of pathologic processes was possible till the microscope and other modern methods of research were applied to the study. This is the special achievement of the German school. The attention directed to processes has led us to recognize that many conditions which used to be looked upon as distinct affections are really different stages in the evolution of one and the same disease. In this way dermatology has been greatly simplified.

Further simplification has resulted from our having learned to distinguish between the primary lesions which are notes of a particular disease and the lesions which result from secondary causes, such as injury from scratching or rubbing and the invasion of pyogenic micro-organisms. Much confusion and needless multiplication of types were caused in former days by mistaking the accidental for the essential in such affections as scabies, eczema, ringworm, impetigo and other conditions liable to complication by suppurative processes.

Pathologic research has done much to elucidate the nature of growths, benign and malignant, of the skin. The work of Jacob Warren, Hutchinson, Dubreuilh and Norman Walker in regard to rodent ulcer, and that of Kaposi in regard to sarcoma of the skin and xeroderma pigmentosum, mark distinct advances.

Real progress in the science of medicine, however, is measured by the increase in our knowledge of the causes of disease. In this respect it may, I think, be said that as much has been done in dermatology as in any branch of medicine. The etiology of a very considerable proportion of skin diseases is now accurately known. Among the causes whose operation has been clearly traced, a prominent place is occupied by inoculable viruses which infect the system, such as syphilis, tuberculosis, leprosy, etc. Ricord, Fournier, Sigmund and Hutchinson have shown how many and various are the cutaneous manifestations of syphilis and with what versatile mimicry it assumes the form of other diseases of the skin. Tuberculosis has been proved to be accountable not only for lupus, but for affections formerly classed under the heads of lichen and erythema and for the other forms of skin disease included under the general term scrofuloderma. The sorting out of the cutaneous affections due to these two causes alone has greatly reduced the region of the unknown in the map of dermatology.

The action of parasites.—Another direction in which the etiology of skin diseases has made decided progress is the recognition of the action of parasites. The idea that scabies is due to the irritation set up in the tissues by the animacule, and ringworm by the growth on the surface of the skin of a vegetable mould, is so familiar to us that it is not easy to realize how recently the truth of these doctrines has been definitely established, and with what incredulity the discoveries were for a long time received. The sarcoptes scabiei had been seen by Avenzoar in the twelfth century and later by Guy de Chauliac, Ambrose Paré and others; and in the seventeenth century it was distinctly indicated as being the cause of itch by Bonomo and Cestoni. It was rediscovered more than once afterward, but it was not till 1834 that Renucci, in Alibert's clinic, was able to show how it could always be found. Yet in 1850 Antony Todd Thomson is allowed to say, without a word of protest from his editor, Parkes, that itch is certainly "the result of a morbid poison, and the fluid of the vesicles or pustules is the agent transmitting the disease," and while awarding Wilson credit for his accurate description of the acarus, Thomson expresses his inability to "accord with him in attributing the disease to that insect." Still later we find a dermatologist like Devergie writing: "The acarus is a morbid product of the itch as the mycoderm is the morbid product of ringworm, as the insect of acne punctata is the morbid product of that disease, as the louse is the morbid product of pediculous prurigo. Ringworm is contagious through the medium of this mycoderm, not only from child to child, but from the head of a child to the bark of certain trees, and the lousy evil from person to person. Ringworm, acne punctata and the lousy evil, do they originate the less spontaneously on that account? The means that we use to destroy the acarus, are they not also suitable for curing the eruption of itch?" The fact that only forty years ago a dermatologist of the first rank could thus in one sweeping anathema condemn root and branch the doctrine of parasitism in skin diseases, is one of the most striking proofs of the youthfulness of scientific dermatology and of the progress which it has made.

The discovery of the vegetable fungi which cause ringworm, favus, tinea versicolor and erythrasma, unlike that of the itch mite, was not made in the Dark Ages, but almost in the full glare of the light of modern science; yet it was received with equally resolute disbelief by some of the leaders in dermatologic Israel.

Bacteria and skin diseases.—The influence of the great revolution in pathology brought about by the discoveries of Pasteur, Koch, and their disciples has been felt in the sphere of dermatology as in other departments of medicine, and we have learned to look for the causes of many diseases in the world of the infinitely little which bacteriology has revealed to us. Already lupus, leprosy, carbuncle, glanders, sycosis, furuncle, impetigo contagiosa have been proved to be the result of the mischievous activity of specific micro-organisms. It is practically certain that syphilis has a like origin, but the particular microbe responsible for its production is still "wanted" by our scientific police. Eczema is considered by Unna, who has done much for the recent advance of dermatology, to be of microbic origin. A similar causation is assigned to psoriasis, and by others to alopecia areata, acne, and certain forms of erythema. Quite recently Sabouraud has brought forward evidence which he thinks sufficient to prove that seborrhea and common baldness are of the bacterial family of diseases.

Other lines of advance.—The most important has been the increased attention bestowed on the relations of various forms of cutaneous affections to disorders of the nervous system. In this field the most notable workers have been Bärensprung, Weir Mitchell, Morvan, Schwimmer, Radcliffe Crocker, and above all Leloir, whose untimely death was a grievous loss to dermatology. A large number of skin diseases presenting the greatest diversity in their objective features have been shown to be dependent on lesion or functional disorder of some part of the nervous system. Many diseases, such as zoster, erythema, pemphigus, scleroderma, and various forms of cutaneous edema, hemorrhage and ulceration, which used to be called "idiopathic"—the medical equivalent for the "visitation of God" in the simple etiology of the British juryman—are now recognized to be consequences of vasomotor or trophic disturbance. We also know that defective innervation plays a considerable part as a predisposing cause, making the skin less able to resist harmful influences of any kind. In this way nervous disorder comes into play as a definite factor.

Another line along which we have advanced is the establishment of a definite relation between certain constitutional states and affections of the integument. The tendency of the French school to look to the general system for an explanation of every blotch and pimple led them away from the truth, no doubt, even to the invention of a diathesis when one was wanted; but some dermatologists have perhaps now gone a little too far in the opposite direction. It is well that with the all-conquering bacillus on every side extending the boundaries of his empire, we should not forget that other agencies have still to be taken into account.

The influence of auto-intoxication requires to be more thoroughly studied than it has yet been; the effects of ptomains should also be fully investigated. The serum treatment which is now being tried in diphtheria and other diseases is making us familiar with toxin rashes.

Progress in power.—Progress has been made in three ways: 1, We have got rid of some superstitions; 2, we know better where to direct our attack; 3, we have more effective weapons.

Among the superstitions that hindered progress one of the most pernicious was the notion that skin disease was a natural issue for the escape of peccant humors—a safety-valve for the constitution. Hence in many forms of skin affection, and particularly in the case of eczema, it was believed to be dangerous to cure the cutaneous lesions, because the disease was thus "driven in" upon the internal organs.

Increased precision in the direction of attack naturally arises from increase of knowledge as to the nature, and especially as to the causation, of cutaneous affections. Nowadays we at least do not, as Archbishop Whately said of the common run of preachers, "aim at nothing and hit it." The polypharmacy in which the older school of dermatologists delighted is almost a thing of the past, and patients are not physicked in the wholesale and indiscriminate manner that used to be thought necessary for the correction of their constitutional depravity. Internal medication is used only in response to definite indications, and we work the "miracle of cure," to use a too celebrated phrase, with the help of a simpler, pleasanter and more efficient pharmacy.

The administration of remedies by hypodermic injection may be mentioned as one of the most promising improvements in constitutional therapeusis; the use of mercury in this way in syphilis is becoming more and more common. The serum treatment has not yet established itself in dermatologic practice, but good results from it have been reported in a few cases of syphilis, lupus, leprosy, and one or two other affections. Tuberculin as first prepared by Koch has in my own hands and in those of some other observers, proved of distinct use as a preliminary to surgical treatment in lupus. The newer tuberculin gives promise of much greater usefulness, but it is too soon yet to pronounce a definitive judgment as to its real efficacy. Thyroid extract has a powerful immediate effect on the integument, but my own experience does not lead me to attach much value to it as a remedy in skin disease, and that opinion is confirmed by the experience of several other dermatologists.

But it is in our means of local treatment that the improvement of our weapons is most marked. The application of the parasitic doctrine to skin diseases has led to the introduction of a large and constantly increasing list of parasiticides; in carbolic acid, boric acid, salicylic acid, resorcin, creolin, thymol, salol, dermatol, ichthyol, chrysarobin, to mention only a few, we have powerful agents that the mid-century dermatologists knew not of. Then both the preparations and the methods of applying them are cleanlier and more effective. The pastes, plaster mulls, varnishes, soaps, sticks, and other devices for the application of remedies which we owe to the ingenuity of Pick, Unna, Lassar, Brooke, and others have revolutionized the local treatment of skin disease. Our surgical methods and appliances, our antiseptics, our cauteries, etc., are also immensely superior to those in use twenty years ago.

We are altogether milder in our methods than the dermatologists of a former day; we soothe instead of irritating; we strengthen instead of depleting; we leave Nature to herself instead of thwarting and teasing her into active rebellion.

The future of dermatology.—Whether the newer medication with serums and organic extracts holds in it much promise for the treatment of skin disease it is of course impossible to say; I am, however, inclined to think that in this direction, and in that of increase of power of dealing with parasitic affections lies the path of development in dermatologic therapeutics likely to lead to the best results. It will be long before a complete classification of diseases of the skin is possible, but this is of no great practical importance. A real stumbling block, however, is the confusion of terminology that still exists: It would be a very real help to progress if a nomenclature at once simple, precise and yet descriptive, and inter [illegible] uld b devised.

ORIGINAL ARTICLES.

LIGATION OF THE COMMON CAROTID ARTERY FOR TRIFACIAL NEURALGIA WITH EXPERIMENTS AND OBSERVATIONS UPON DOGS.

Presented to the Section on Surgery and Anatomy at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY B. MERRILL RICKETTS, PH.B., M.D.
CINCINNATI, OHIO.

The frequency, severity and want of remedial relief from trifacial neuralgia has prompted a most extended research, not only into the literature but also the pathologic conditions of the minute structures involved, as determined from an experimental point of view; and as a report of the case operated upon by myself in July, 1896, was made within several weeks of the operation, I will make but casual mention of the condition found within those few weeks. It is, however, gratifying to state that the good results derived from that operation have been permanent.

Before entering upon the experimental feature it is necessary to understand that the anatomy of the dog is practically the same as that of the human being. Especially is this so in reference to the arterial and nervous system of the head and neck, and even the sympathetic system in this region is but little, if at all, dissimilar to that in man. Literature is not wanting in evidence that the common carotid artery may be ligated in almost any pathologic condition with impunity, but recorded observations are few concerning this procedure as a means of relieving neuralgia of the fifth nerve.

English, German and French investigators have each contributed comments that are highly interesting.

Trousseau did the operation, but Nussbaum was the first, losing the case on the third day by hemorrhage, while *case 2.*—(March 9, 1862, F., aged 22), recovered with slight paresis in the affected side, which disappeared on the fourth day with return of pulsation; he does not say whether this case again experienced pain.

Case 3.—Male aged 40 years, duration many years, was operated on October 30, 1862. Stupor lasted for eight days, then sudden return to consciousness without pain. Complete paralysis occurred on the side operated on within twelve hours, lasting four weeks, when sensation returned, followed slowly by motion, relief from pain being constant.

Case 4.—F., aged 38 years, duration nine years, had operation November 8, 1862; no result.

Case 5.—F., aged 60 years, was of several years' duration. Various other operations had been made. Ligation resulted in cure. Atheroma at bifurcation.

Case 7.—Female, five children, operation September 14, 1865. Cured. Died 1876; no return.

Case 8.—Male, aged 45 years, ten years' duration. Ligation June 30, 1877. This is the third time this case has been reported cured (Fowler).

Case 9.—Male, aged 41 years, operation keratitis; lost eye.

Case 10.—Young, hyperemia of side of face. Ligation; instant relief. No recurrence sixteen years later.

Case 11.—Female, aged 32 years, right side, hyperemia of face and scalp; ligation; immediate and permanent cure.

Case 12.—F., aged 63 years; ligation; cure.

Case 13.—Only temporary relief even after dividing nerve at foramen rotundum.

Case 14.—Male, relief eleven months, then divided at foramen rotundum with complete cure.

Case 15.—A monk, eight years' duration, hyperemia and burning right side of face, head and neck. Died with erysipelas.

Case 16.—Male, aged 49 years, thirty years' duration; ligation; no relief.

Case 17.—Male, aged 64 years. Ligation, then neurectomy of inferior dental nerve; permanent cure.

Case 18.—Parotid tumor removed without relief. The scar pressure gave occasional relief. Ligation of common carotid gave complete cure.

The ophthalmic is the branch most frequently the seat of pain, and the superior maxillary next in frequency. The origin may be either central or peripheral or both.

Causes.—While anemia has been ascribed as being perhaps the most common factor in producing pain in this lot of nerves as in others, it must be remembered that any degree of anemia from any cause may exist without pain in any part of the body. Congestion is also a most potent factor in causing pain, and why not in connection with this ganglion and its branches? The right ganglion is the most frequently affected.

These conclusions are derived from my personal observations. However, there are no apparent reasons why one should be affected more frequently than the other, their anatomic relations being identical.

The first branch passes through a bony canal, and makes its exit through a hole or fissure, which fact creates a reasonable probability that the channel may often be narrowed by exostoses or thickening of the periosteum, either of which would cause pain. To meningeal adhesions it is also an easy matter to assign the cause of trifacial neuralgia, and especially may this be so in circumscribed meningitis about the ganglion. Lying as it does between the dura and the bony ridge and the petrous bone beneath the dura, it is readily conceived that adhesions to the dura or adhesions of the dura to the bone would probably produce pain. Then, too, the weight of the brain pressing upon the ganglion which rests upon a bony foundation, may be found to add to the environments conducive to pain. This is the only ganglion which rests upon bone. Middle ear inflammation and fracture of bones associated with the ganglion and nerves may produce either anemia or congestion sufficient to give rise to pain.

Experiments and operations on dogs.—Assisted by Drs. P. C. Logue and P. M. Ashburn. Before entering upon these cases it may be well to give a brief description of the vessels and nerves in the neck, head and face of the dog.

The analogy existing between man and dog as respects these structures is very striking indeed. The carotid artery in the right side arises from the innominate, and on the left side from the arch of the aorta as in the human subject, and pursues a very similar course, inclosed in its sheath and accompanied by the internal jugular vein and pneumogastric nerve. The size of the vessel is very much smaller in proportion to the size of the animal possessing it than would be expected, and bifurcation takes place at a much higher level than in man. After division the external carotid gives off its branches, position and distribution very similar to the external carotid in man. The internal carotid is also given off at a higher level and appears more as a branch of the external carotid than as a bifurcation of that vessel. It arises from the external carotid at about the level of the hyoid bone, and after passing upward and backward deeply seated beneath the muscles of the neck, enters the carotid canal in the petrous portion of the temporal bone to reach the cranial cavity. The only portion of the vessel that is of very great interest as respects these experiments is the intracranial portion. After entrance into the cranial cavity the artery passes close to the inner side of and below the Gasserian ganglion, giving off one or two and in some cases three delicate twigs to supply it. The middle meningeal branch of the internal maxillary also passes to the inner side of the ganglion and supplies it with arterial blood.

After ligation of the common carotid artery it was hoped that there would be some possible diminution in the size of the vessels, especially those supplying the ganglion above the point of ligation, but this was only apparent in two cases out of the six operated on.

Enough has been said about the gross anatomy of the arteries, and with a brief description of the fifth nerve and its ganglion, I will close this part of the subject. The origin, course, division and distribution of the fifth nerve in the dog is so very like that in man that only light mention will be made of it. The deep portion of the nerve passes over the superior border of the apex of the petrous bone to form the Gasserian ganglion, after which the three branches are given off and make their exit from the skull through their respective foramina. The Gasserian ganglion lies at the apex of the petrous bone on its anterior surface external to the dura and is exceedingly large, even in dogs of small size.

The technique of the operation was as follows: After etherization (dogs tolerate this anesthetic much better than chloroform) an incision was made in the line of the common carotid, the sternoclidomastoid muscle affording an easy guide to the position of the vessel. After exposure the artery was ligated with silk-worm gut and the skin incision closed by a running suture of the same material. No antiseptic precautions were taken, and in all cases primary union was secured. Apparently the animals suffered but the slightest shock from the operation, as they were up and about a few moments afterward. The time they were allowed to live after the ligation varied from two to eight weeks. The injection used for dissection, with a few modifications by Dr. Layne, my house surgeon, who made the dissections, was given me by Professor Lewis, Professor of Anatomy in the Cincinnati College of Medicine and Surgery, to whom I am indebted for this valuable and novel procedure. The basis of the injection is ordinary corn starch in the proportion of a pound of starch to a pint of water, to which is added anilin in sufficient quantity to give the desired tint. Instead of using water alone, alcohol and water in equal parts was substituted and found to be more efficacious, as the alcohol does away with the necessity of a preservative and it is also possible to throw a larger quantity into the vessels and thereby secure a more perfect injection of the subject. The alcohol is taken up much more quickly by the tissues than is the water, and in a very short time (ten minutes) the starch has hardened sufficiently for work. The injection secured by this method is the best I know of, the smallest capillaries being readily permeated by the fluid starch, an end which is not easily attained with parafin, wax, etc. Dissection was begun as soon as the injection had hardened, and the following observations noted:

Experiment 1.—Ligation of the common carotid of two weeks' duration; vessel obliterated for a short distance above and below the ligation, no apparent alteration in size of trunk or branches above this point; brain beautifully injected on both sides.

Experiment 2.—Dissection at the end of three weeks; vessel occluded at point of ligation; no change different from Case 1.

Experiment 3.—Dissection on the twenty-fifth day; no noticeable alteration in size of vessel above point of occlusion.

Experiment 4.—Dissection on the thirtieth day; vessels on the side opposite the ligation manifestly enlarged, especially the infra-orbital branch of the internal maxillary.

Experiment 5.—Dissection at the end of the fifth week. No perceptible change in the size of the vessels on either side.

Experiment 6.—Dissection at end of eighth week; vessels on opposite side of ligation perceptibly enlarged.

It will be seen that nothing of value in so far as diminution of the size of the vessel is concerned was gained from the above experiment. This must be attributed to the free anastomosis that exists both inside and outside the cranial cavity in the dog. It was found that after ligation of both common carotid arteries the brain could be perfectly injected, the fluid readily passing through the cerebral arteries. The starvation theory is therefore not tenable, and something else must be sought as the cause of cure after ligation of the common carotid artery.

The microscopic examination of the ganglion of Gassa was made by Dr. D. I. Wolfstein, who writes the following:

May 30, 1897.

Dear Dr. Ricketts:—The specimens you gave me to examine, in which you wish to know whether there was any evidence of structural change or any difference in the appearances, were duly stained. The specimens were the Gasserian ganglia, the presumably abnormal one being tied with a piece of string. They were stained both with thionin and with hematoxylin and both showed perfectly normal ganglion cells. With thionin, the usual beautiful differention of chromato- and achromatophilic substance seemed identical in both. I am unable to find any difference whatever. D. I. Wolfstein.

Conclusions.—1. Ligation of the common carotid without pathologic conditions is attended with but little danger.

2. It is safer, more certain and attended with fewer serious consequences than any of the intercranial operations for trifacial neuralgia.

3. The causes seem to be either congestion or anemia.

4. When congestion, the relief is more certain by ligation.

5. The close proximity of the ganglion to the bone upon which it rests, and the weight of the brain upon it, together with localized meningitis, seem to explain in some degree the causes of anemia and congestion of the ganglion.

6. Cell structure of the ganglion is not changed by ligation of the carotid artery, and therefore can not be ascribed as the cause of relief from pain.

7. As the size of the blood vessels on the side ligated do not seem to be lessened at the end of eight weeks, the cause of relief evidently lies in the fact that the tension of blood is much lessened. The lessening of arterial tension in any congested area gives relief, and why not in this instance?

8. However uncertain the cause of pain or its relief may be, ligation of the common carotid for trifacial neuralgia is an established operation.

ON THE LOCAL ABSTRACTION OF BLOOD IN THE ARTHROSES OF THE EXTREMITIES.

Abstract of paper read in the Surgical Section at the Twelfth International Medical Congress, at Moscow, Russia, August 21, 1897.

BY THOMAS H. MANLEY, M.D.
PROFESSOR OF SURGERY IN THE NEW YORK CLINICAL SCHOOL OF MEDICINE, NEW YORK.

In a considereble number of joint lesions of the extremities dependent on trauma or various pathologic conditions, our resources are often taxed in an endeavor not only to relieve our patient as promptly as possible, but also to restore the full functional use of the limb. It is our aim, further, in our management of the case to be quite certain, whatever we do, not to leave a condition possibly worse than what we find.

Of late years the shibboleth has been "*rest, rest,*" immobilization and fixation, or the free and almost indiscriminate employment of the scalpel.

Rest, or the support of an injured joint is indispensable in a considerable number, but as the panacea some would have us believe, it is a fallacy. By surgical operations, the aid of anesthetics and aseptics very many limbs and lives have been saved which formerly were lost, though even here every unbiased observer must admit there is altogether too much cutting being done for joint lesions.

Our great aim in treatment should be to attempt the arrest of morbid processes before they have advanced to the point of destruction, or in other words, at an early date apply energetic prophylactic measures.

Among those in my own experience there is no single remedy so prompt, positive and potent in action as the local abstraction of blood, either by acupuncture, leeching, scarification or deep puncture.

Fashion rules in medicine as in the social world. Hahnemannism and the homeopathic school came and blood-letting went; not only that for constitutional maladies, but every phase of disease, so that it is difficult today to find a recent graduate in medicine capable of performing phlebotomy or wet-cupping a patient.

In order to recognize the class of cases appropriate for local depletion and have a proper appreciation of the morbid condition existing, a familiarity with the various pathologic phases of the lesion is necessary.

It is furthermore important to always bear in mind the fact that various states of the constitution influence local joint inflammation, which will early yield after those have been treated.

It may be briefly stated that the class of cases most appropriate for local exsanguination is that succeeding injury of the joints, those in which recovery is retarded by a hysteric element and many other conditions by no means well understood, nor is it necessary to employ it until other palliative measures have been thoroughly tested. It is immaterial whether inflammation be present or not. In fact, in some of the most rebellious cases the source of the greatest pain and degree of infirmity are in those joints entirely devoid of evidence of the presence of inflammation, nor is it any consideration whether the patient is anemic or plethoric. In the local abstraction of blood but a small quantity is removed. In any event what our patient in most cases needs is not more blood, but better. Relief from apprehension, restoration of sleep and use of the limb will soon stimulate nutritive energy of the system into renewed action. And furthermore, it is a well-known physiologic fact that the vessels always carry a surplus of blood, which if not discharged excessively is very soon regenerated.

Mode of procedure.—In all cases, having decided on the vascular depletion of a joint, it must be done thoroughly, with a free and firm hand. In many the leech alone or the scarification suffices, but in severe or chronic cases my own preference is for the long narrow-bladed bistoury, carrying the point down to and through the periosteum, the perichondrium, or even through the capsule. It is only necessary to be aseptic and to clear the main blood trunks. No anesthetic of any description should ever be employed, for the psychologic effects on the sensorium is undoubtedly the most potential element in relief; nor is it desirable to occupy time with detailed preliminaries lest the patient lose heart at the last moment and refuse operation.

By whatever means we proceed precision and rapidity are important. The parts are sensitive and the deep punctures painful, hence the demand for celerity of action. The blood should be permitted to flow as freely as possible and when it ceases simple dressings are to be applied, when the patient should be encouraged to use the limb as freely as possible. In certain cases it may be necessary to repeat the local exsanguination.

It may be remembered that it is only recommended as an adjuvant to other regular systematic treatment, but it is one of the most valuable. One has but to amply test it to be convinced of its efficacy in a class of arthroses often exceedingly trying to the patient and surgeon alike.

While recognizing the salutary influence of affecting the emotions in all cases, especially those in persons of a hysteric tendency, the *rationale* of this procedure may be further explained by the direct effects on the soft parts extrinsic to an articulation. There is generally in the greater number of the most painful cases a congested state of the capillaries, conjoined with a phlebitis which involves the subcutaneous, the subaponeurotic and deeper trunks. In the venous circulation of the extremities all the valves from within open toward the periphery, so that when the reticulated meshwork in the integument is freely opened all the deeper congested vessels are freely drained outward, tension is relieved and large territories of static over-congested vessels emptied.

In some cases wherein all the signs of inflammation are absent, except pain, the dominant pathologic change is evidently in the nerves and the absorbents. We have a multiple neuritis, with muscular spasm and hyperesthesia. In these cases surface or deep scarification with free vascular depletion is a remedy of the highest value.

There is nothing novel in the line of therapy here recommended. It is only a plea for a time-honored powerful remedy, which the writer is old-fashioned enough to recommend and which has no rival. It goes without saying, that all cases must be carefully studied and their nature well understood before submitting them to the plan of treatment described.

The above may not be regarded as progressive science, but we know that of late years the therapy of many infirmities and maladies as laid down by several authors is to do *nothing,* but wait and "*rest.*"

INTERESTING STONE CASES.

BY D. M. B. THOM, M.D.
MARDIN, TURKEY IN ASIA.

Case 192.—An Arab from the Plains, about 55 years of age, came to the hospital April 17, complaining of pain in urinating; had suffered for some time, as many scars of the hot iron over the region of the bladder testified. He was of good build, fairly nourished, but had a terrible dread of the knife, and would not listen to the operation by lithotomy. I explained to him that if the stone was sufficiently friable I could remove it without cutting, provided it was not too large to be grasped by the lithotrite. So on those conditions he became an inmate of the hospital, and the work of crushing began. The stone was found to be very large, but I was able to grasp and crush portions of it. After crushing as much as I thought advisable at one sitting, I proceeded to withdraw the lithotrite (Thompson's), which was accomplished with considerable difficulty, the female blade being so impacted as to make it impossible to screw the male blade home, causing some laceration of the mucous membrane of the urethra. I also had to enlarge the meatus in order to withdraw the instrument. It caused him but little inconvenience. He was ready for another sitting the second day. He had passed quite a number of pieces, and seemed very much encouraged. We had some five sittings, crushing a tremendous amount of stone, but each time experienced greater trouble in withdrawing the lithotrite, until I suggested completing the operation by lithotomy. He said he could not listen to that; as he was afraid that after cutting he would not be able to do horseback riding again, and that he would go to a friend's house in the city for a few days and see how he felt. That is the last I have seen of him. It is reported by his friend that he passed great quantities of débris, and that he was now fully recovered.

Case 196.—An Arab, about 60 years of age, a tall, lank, lean, gaunt-looking specimen of humanity, ill nourished, but possessing great nerve power and endurance. Some six years ago he presented himself complaining of pain in the bladder and difficulty in urination, but for some reason he disappeared, and did not show himself again until May 20 of this year. On again examining him I found he had a stone of large size. He confessed that he had been troubled with it for twenty years, and there was certainly proof enough over his abdomen that it had been there for some time. From the pubes to the ensiform cartilage there was not a spot as large as a silver dollar that had not been scarred by the red hot iron. He was informed that the stone was large, that its removal would be difficult; but he insisted on saying that it was not large, as he had measured it himself by passing his finger up the rectum. The same day he was examined he was present at an operation where a stone was removed measuring 9x10 centimeters; he said, "Mine is no larger than that." After trying the lithotrite and being unable to get it between the blades, I urged him to allow me to perform the suprapubic operation, but he would not listen to that; so on the following day, after making another ineffectual attempt to grasp and crush it, I cut down through the perineum, entering the bladder, and to my consternation found the organ full, a solid mass, immovable in any direction. My incision was as large as the parts would admit, expecting to meet with a large stone, but not a boulder. I took the large forceps applying it in different ways, hoping I might be able to move it, but to no purpose. I again tried the lithotrite, but the blades would not come near each other. So using the forceps as a fulcrum to press the stone up over the pubes, I cut down in the median line. Coming on the bladder I found it greatly thickened, resembling a muscle rather than the bladder. An incision fully three inches long had to be made before it could be extracted. Much of it was crumbled off in the effort to withdraw it, both above and below, but I succeeded in removing a solid mass weighing 80 drachms, measuring 9.5 by 7.5 inches. Fully 20 drachms of it was thus lost, so that we had the stone lying in the bladder, before touching it, weighing 12½ ounces. The upper wound was closed in the usual way, leaving the lower to do the draining, which to my mind, was what saved him, he being in the balance for a day or two. He began to show signs of gaining, and made a fairly good recovery, leaving the Hospital March 22 with only a small opening in the lower wound, which he had begged of me for a number of days to sew up as I had done the wound above.

Case 201.—June 19, 1897, a child three years of age was brought, complaining of pain in passing water; he was examined and found to have stone. He was at once operated on, and being anxious to remove the stone without introducing my finger, I entered the bladder all right, grasping the stone, which went to pieces under the forceps, I removed everything I could find with the instrument and washed out the bladder with great care, hoping, yet doubting, that all had been brought away. The child was making a fair recovery, yet the old symptoms were as prominent as ever, so in July he was again brought and examined,and there was stone still remaining. I enlarged the former wound, making it large enough this time to introduce my finger. I found the bladder in the form of an hour glass, with the stone in the upper half. Expanding it with an injection of water, I removed about twice as much as I did the first time, my finger being within the bladder. I could find nothing more, yet he is not free from the old symptoms. It is a nice operation, if the stone can be extracted whole, not to introduce the finger, but when the stone is crushed in the extraction, nothing can give the positive evidence that the bladder is free from all débris but the introduction of the finger.

Case 202.—Our misfortunes, or unfortunate cases, do not look as well in print as the more fortunate and brilliant ones do; but it is through the misfortunes of one that others learn to avoid them, and for that reason it is our duty to give them publicity with the same candor we do our more successful cases. For that reason I will close with two of what I call unfortunate cases. This last case was operated on yesterday, the second of the kind in 202 cases of calculus it has been my fortune—and some of my patients' misfortune—to operate on. A child of three or four years of age, well nourished and in fine health, was brought to the hospital some five or six days ago. The father, who was with him, says that for nearly a year he was troubled by spells of having pain in passing water. I examined him and at once got the click of the stone. Yesterday he came prepared for the operation. The father said that since he was examined he had been free from pain in passing water. On introducing the staff I again got the former click, and making the wound large enough to introduce my finger, imagine my surprise and utter chagrin on exploring the length and breadth of the bladder not to find a stone in it! The case is doing well, but what was it I mistook for a stone?

In looking back through my records I find Case No. 72, aged 3 years, Turk, a very delicate child. In sounding no audible click was heard, and for that reason was removed from the operating table. The symptoms continued the same. The parents insisted on my trying again, which I did, with the same result. The sound seemed to come in contact with something, but getting no clear sound I refused to operate. The child suffered so much from the pressure of water that the father insisted on my operating; I consented, giving it as my opinion that it was unwise to do so. On entering the bladder, no stone could be found! Inflammation set in, carrying off the little fellow in twenty-four hours.

All these, in fact all my operations, are done without any assistance, except as my servants help.

July 8, 1897.

THE TREATMENT OF HEMORRHOIDS BY THE INJECTION METHOD.

Presented to the Section on Surgery and Anatomy, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4. 1897.

BY LEWIS H. ADLER, Jr., M.D.

Professor of Diseases of the Rectum, Philadelphia Polyclinic and College for Graduates in Medicine, Surgeon to the Charity Hospital, and to the Out-patient Department of the Episcopal Hospital; Prosector to the Professor of Anatomy, Medical Department University of Pennsylvania.

PHILADELPHIA, PA.

I am sure that my experience is by no means unique, in that the majority of patients with hemorrhoidal troubles come to me greatly prejudiced against any operative procedure involving the employment of general anesthesia, and especially the use of the knife. These objections have been raised not only by the laity, but also by physicians who have been similarly affected. Such an argument should not and would not prove a factor in altering the character of advice to be given to a patient were I satisfied that only one plan of treatment could effect a cure; but where a choice of several methods exists for effecting the same or similar results it is not only our duty but a necessity for us to respect the patient's wishes.

In a number of instances, sufficient to convince me of the efficacy of the method and to enable me to place my opinion on record, I have treated internal hemorrhoids (in selected cases only) by the injection of carbolic acid. The results obtained in every instance have been entirely satisfactory to patient and myself.

I am thoroughly acquainted with the unsatisfactory experience and the unfavorable opinions expressed regarding this treatment by such authorities as Kelsey of New York, Mathews of Louisville, Ky., Allingham of London, and others of equal eminence, and I am, furthermore, free to confess that for a long time the weight of this evidence deterred me from giving the method a trial. On the other hand, I have diligently perused the literature, past and present, dealing with the other phase of the question, and after reading the excellent treatise on "Hemorrhoids and other Non-malignant Diseases of the Rectum," by W. P. Agnew, M.D. of San Francisco, I determined to test the merit of the treatment.

External hemorrhoids.—Agnew (*op. cit.*, p. 18) admits that the quickest, neatest, least painful and most desirable way of disposing of any form of external hemorrhoid, cutaneous tag or like redundant tissue is by excision, but employs the carbolic acid injection in those cases in which the patient is averse to being treated by any plan involving the use of the knife or scissors. He claims that this method effects a cure, to which such persons will readily submit, although informed that a longer time is required for the complete eradication of a tumor thus treated and that more pain and inconvenience may be experienced from the effects of the operation than would result from that by excision.

Personally I have had no experience with this method of treating external hemorrhoids, preferring and always advising in operative cases the excision of such tumors.

According to the same authority (*op. cit.*, pp. 22, 23 and 24) and as the result of his observations the objections to the treatment of external hemorrhoids by carbolic acid injection pertain solely to the length of time required for the removal of the tumor, a period of three or four days, and the pain following the injection, which is not intense, but is at times more or less annoying; usually beginning within one or two hours after the operation and continuing for twelve or fourteen. Agnew advises against the employment of this method in the treatment of external hemorrhoids when inflamed and in a highly sensitive state. He especially notes the care that should be taken when operating on these tumors by injection to see that quite a considerable portion of the cutaneous surface, especially at the summit of the pile is affected by the solution applied just beneath the skin, otherwise the skin will become inflamed, in order to let out the interior coagulum, which he has often seen come out in three days, without suppuration or showing the appearance of much moisture and in one unbroken cystic-looking mass. The operation is to be performed with a view of cauterizing all the tissue to be removed, which can be governed only by the dictates of judgment and as a result of experience.

Internal hemorrhoids.—It is to the treatment of internal hemorrhoids by the injection of carbolic acid that I wish especially to invite your attention in the hope of eliciting a free discussion as to its merits or demerits based upon the actual experiences of those who have given the method a fair trial.

Formula.—The formula which I use is the one advocated by Agnew, and the method of its preparation is best detailed by a verbatim description as given in Dr. Agnew's work on diseases of the rectum (*op. cit.*, pp. 35 and 36):

"The solution of carbolic acid found to be uniformly successful in the treatment of hemorrhoids is prepared by first making a solution of the acetate of lead and borax in glycerin in the proportion of two drams each of the chemically pure salts to one ounce of Price's glycerin:

℞ Plumbi acetat.
sodii biborat. . . . . āā ʒ ij 8,00
Glycerinæ . . . . fl. ℥ j 32,00

"Mix in a graduate, pour into a two-ounce vial, and let it stand for twenty-four hours. The solution of the salts is hastened by placing the vial in a warm water bath and allowing it to remain there for fifteen or twenty minutes. The glycerin can be handled to a better advantage and its measurements more accurately made and retained by warming it as well as the graduate before it has been poured into the graduate and the chemicals have been added.

"Select Calvert's No. 1 crystallized carbolic acid and pour a sufficient quantity, liquefied by warmth, into a two-ounce graduate to measure one ounce and add two drams of distilled water. To this add enough of the glycerid of lead and borax previously made to make the combination measure exactly two ounces.

℞ Acid carbolic (crys.) . . . . ℥ j 32,00
Aquæ destillat . . . . fl. ʒ ij 8,00
Sodii biborat. et plumbi acetat. et glycerin. fl. ʒ vj 24,00
Misce et sig. Solution for hemorrhoids.

"The object of the formula is to lessen the syrup-like consistency of the preparation. Should equal parts of crystallized carbolic acid and the glycerid of lead and borax be combined, the solution will be found rather too heavy for convenience. It will not flow through the hemorrhoidal needle as freely nor take hold of the tissues when injected as quickly as does a solution containing a small proportion of water. Be particular in the weights and measurements and the purity of the ingredients entering into this preparation, as anything unnecessarily irritating should be scrupulously avoided. I have tried synthetic carbolic acid and found the odor of tar to be decidedly stronger, and believe it to be much more acrid and irritating than the commoner preparations; neither can I see that anything is gained in using vegetable glycerin.

"Some make no allowance in attempting to give the formula, for the increase in bulk of the glycerin occasioned by the addition of the one-half ounce of solids, and direct that the ounce of carbolic acid be added to the full amount of the glycerid of lead and borax when made. By this inadvertence not much over a 35 per cent. solution of carbolic acid is obtained. After trying the acid in varying strengths and watching its effects, I have concluded that not less than a 50 per cent. solution should be used. The addition to the solution of the acetate of lead is designed to restrict the action, and that of the borax to lessen the irritative properties of the acid. The acetate of lead not only keeps within limit the distribution of the acid at the time the solution is forced out of the hypodermic syringe, but of itself combines with a certain portion of the albumin of the blood and other tissues, forming the albuminate of lead. If I were to make a change in the formula it would be toward an increase rather than a diminution of the quantity of acid."

Preparatory treatment.—This includes a careful study of the patient's physical condition. I would advise against the employment of the injection treatment in cases predisposed to phthisis or already affected by this disease, and in diabetes or in chronic diseases of the liver, heart or kidneys.

During an acute inflammatory attack of hemorrhoids is not a favorable time to operate, on account of the engorged condition of the rectal vessels, and the irritability of the mucous membrane of the bowel. Such conditions should be relieved by local medication and by remedies directed toward regulating the bowels and increasing the activity of the liver.

Operation.—At the time of operation the hemorrhoids are exposed by inducing the patient to have a stool or to sit over hot water.

It is advisable to smear vaselin over the mucocutaneous surfaces prior to operating, as advised by Agnew (*op. cit.*, p. 34), in order to prevent the solution used for the injection coming in contact with the parts.

The patient should be placed in Sims' position and the hemorrhoid being sufficiently well exposed, it is be punctured at its most accessible point, preferably about midway between its base and apex, and the point of the needle passed to about the center of the growth. Care must be exercised that the needle's point is inserted beyond the proximal end of its opening, as otherwise the preparation will be injected on the outside of the tumor. In a large growth eight or ten punctures may be found necessary.

The injection is to be inserted slowly, several drops at first, then drop by drop, watching the action of the solution as shown by the change of color that creeps over the surface of the pile. This change of color, Agnew states, is quite marked with hemorrhoids of a delicate coloring, less so with those possessed of more fibrous coats. The needle should be held in position for a short time, and if the quantity injected appears to be less than needed, more of the solution should be used. Agnew states that the solution takes effect slowly by virtue of its astringency and syrup-like consistency, and no doubt extends some farther than is always apparent at the time of operating. If the hemorrhoid be large and its cavities filled with blood exhibiting strong arterial pressure, more time will be occupied in performing the operation than is generally supposed, as many as twenty or thirty minutes occasionally being required. The time is taken up in such cases, by holding the needle in place until assured that sufficient of the solution has been used to effect the desired result. If the part feels doughy or springs up under the finger like an elastic ball when pressed, or blood flows freely through the place of puncture after the needle has been withdrawn, either enough time has not been allowed for the preparation to take effect or a sufficient quantity has not been injected.

After the entire cavity of the tumor has been thoroughly reached by the injection, and in a large tumor, a few drops have been deposited on the surface of the pile, so as to be sure of thoroughly cauterizing the more dense tissue of the integument, which Agnew states might otherwise inflame and create unnecessary pain and suffering, the hemorrhoid is to be thoroughly dried and covered with carbolized vaselin and returned within the bowel. Several tumors may be treated in this manner at one operation and I have seen no bad results ensue, although I have used several drams of the solution in a single treatment. No speculum is required, as a rule, in this method of treating hemorrhoids.

The needle required for the hypodermic syringe employed in giving these injections should have a little larger bore than the needle employed for ordinary hypodermic use, so as to permit the fluid to flow through readily, which the smaller needle prevents owing to the consistency of the injection fluid.

After-effects and treatment following operation.—In some cases pain is experienced several hours after the operation, but is usually controlled by suppositories of the aqueous extract of opium, ¼ grain, and extract of belladonna, ⅛ grain, used *pro re nata.* Difficulty in urination may occur and is usually relieved by a hot-water bag applied above the pubes, or by a sitz bath. Catheterization is seldom required. A desire to have the bowels move can be allayed by the use of the suppositories and by hot water compresses applied to the anus.

I do not endeavor to confine the bowels for any definite period after this operation; usually the patient's fear of having a movement effectually restrains such a desire, and on the third day I am in the habit of ordering fractional doses of calomel and soda, followed by a saline. Just preceding the time the bowels act I order a rectal injection of 8 ounces of carbolized oil (2 per cent. carbolic acid) or an injection of slippery-elm tea or of borax water (a dessertspoonful to the pint of water). A peculiar odor sometimes noted when the coagulum is being thrown off, should not be interpreted as indicating suppuration.

Agnew states that to effect a safe, speedy and radical cure of a case of hemorrhoids, it is desirable to get rid of the tumor bodily, not by shrinkage or contraction, leaving a hard or indurated prominence subject to resuscitation and a return of the old malady, nor by inflammatory destruction, but by a separation of the spongy and vascular growth from the normal tissue of the body, the same as if it were dissected from its remotest attachments. This is obtained by putting a sufficient quantity of the preparation recommended just where it is required, and such results will invariably follow. My experience with the treatment thus far leads me to endorse most heartily Dr. Agnew's strong commendation of the method which he has so successfully employed for a long time. Personally, I can not speak authoritatively regarding the permanency of the cure effected by the carbolic acid injection in hemorrhoids, for I have not had an opportunity of observing cases treated by this method for a longer period than two years, but from my observations I am inclined to believe that it is a radical procedure.

Regarding the dangerous results following this treatment—of carbolic acid poisoning, embolism, sloughing and ulceration, or their sequelæ, abscesses or fistulæ, I have not witnessed any such results and am loath to believe that they do occur if the operation be performed carefully and skilfully and with a proper observance of aseptic principles.

1610 Arch Street.

DISCUSSION.

Dr. BROWN of Indian Territory—I have operated on more than one hundred cases. Upon injecting carbolic acid I found the pain was increased, but when we used the chemically pure acid the pain was mitigated more than by any other. We also found that in this way there was no pain after the first few seconds, unless we happened to get the acid around the outside. We have much less chance of its being absorbed. By injecting one hemorrhoid the whole mass will disappear, and one application is usually sufficient. I do not know exactly from what cause these results ensue, but the disappearance of the whole amount of hemorrhoids showed that the acid had been absorbed.

Salicylate of Methyl in Rheumatic Arthropathy.—The benefits of local applications of salicylate of methyl in arthralgia accompanying infective disease have recently been proclaimed, and a similarly beneficial effect has been observed in the arthropathy of subacute or chronic rheumatism after about 3 grams have been applied to the articulation. The secret of success is to enclose the joint afterward hermetically. For this purpose it is laid on a piece of rubber tissue, the salicylate of methyl rubbed in and the rubber tissue drawn up tight around it, enclosing the whole hand or foot as the case may be. Cotton may or may not be used inside.—*Presse Médicale*, July 28.

CICATRICIAL STENOSIS AND VALVE FORMATION AS A CAUSE OF PYLORIC OBSTRUCTION, WITH A REPORT OF FIVE CASES RELIEVED BY OPERATION.

Presented to the Section on Surgery and Anatomy, at the Forty-eighth Annual Meeting of the American Medical Association, held at *Philadelphia, June 1-4, 1897.*

BY W. J. MAYO, M.D.
SURGEON TO ST. MARY'S HOSPITAL,
ROCHESTER, MINN.

Non-malignant forms of pyloric obstruction are not infrequent and have, I believe, been commonly confused with cancerous disease and, with some exceptions, allowed to die without surgical intervention. When the stenosis results from the cicatrization of an ulcer which had existed years previously the patient may be in middle life or later before the obstruction becomes marked and the cachexia of chronic starvation closely simulates that of malignant disease.

Now and then cases operated upon by such masters as Senn, Lange, Weir and others have appeared in American literature. European operators have been more advanced in this respect and have furnished many important contributions to the subject.

Stricture of the pylorus following upon the healing of gastric ulcer is the most common form of non-malignant obstruction and four out of five cases upon which I have operated have been of this variety. The site of previous ulceration in these cases was along the lesser curvature and anterior surface of the stomach, and in two the cicatrix was very extensive, a prolongation extending downward in the the pyloric region and causing great distortion of the canal. In two of the remaining cases the strictured area was narrow and circular in form, one with its origin in a cicatrix along the anterior wall and the other having no apparent cause. In these two cases the dilatation of the stomach was extreme, although the mechanical obstacles to its emptying were not so great as in the three cases in which the scar tissue was more extensive. In one of these two cases the pylorus was held up very high by a short gastrohepatic omentum, and in both cases the downward sagging of the stomach produced a well-marked kinking or valve formation at the pylorus, which evidently was obstructive in its nature.

In a case which died from chronic starvation, supposed to be due to pyloric obstruction of a cancerous form and therefore not subjected to operation, the postmortem showed a large fibrous hypertrophy, such as described by Greig Smith, with obstruction not of a malignant nature.

The pylorus was stenosed, yet not to a marked degree, the strictured portion easily admitting a lead pencil. There was no evidence of previous ulceration. Here again this valve formation was well marked.

Some observation of the two cases operated upon and experiments made with the postmortem findings just referred to leads me to believe that a pylorus somewhat rigidly held upward by a short gastrohepatic omentum, or one in which a certain amount of mechanical obstruction is present will permit sagging of the stomach and valve formation of the pylorus, with consequent obstruction.

It is possible that this condition may exist in many cases of chronic gastric catarrh and dilatation without producing sufficient trouble as to cause death or require operation.

The production of valve formation at the pylorus is similar to the valve formation of the ureter at the pelvis of the kidney as a cause of hydro- and pyonephrosis so graphically portrayed by Christian Fenger.

Enteroptosis favors such obstruction, as the greater the sagging of the intestines and the greater the downward displacement of the stomach the more perfect are the mechanical conditions which tend to valve formation.

One year ago I read a paper before this Section on a similar subject and referred to valve formation as a possible cause of the difficulty at the outlet of the stomach, and I am now still more confirmed in the belief then expressed. It certainly explains many of the changes incident to the causation of obstructive symptoms without previous local disease.

Kussmaul, on the cadaver, has been able to produce a rotation obstruction which is evidently similar in nature. A few cases of congenital stricture have been reported by Landerer and Maier.

It is altogether questionable whether movable kidney can produce mechanicel pyloric obstruction, although this conclusion has been drawn as to the relief of gastric symptoms supposed to be given by nephrorrhaphy in neurasthenic women.

The diagnosis of marked pyloric obstruction and the consequent dilation of the stomach is not difficult, in fact the vomiting of large quantities of ingested material or its removal by the stomach-tube is of itself significant. After inflating the stomach with atmospheric air, by means of an ordinary valve syringe and a stomach-tube, its outline can be rendered evident to the usual methods of physical diagnosis, inspection, palpation, percussion and auscultation. The gastroscope and the gastrodiaphanoscope have little practical value to the surgeon. The differentiation between the malignant and the non-malignant forms of obstruction is often difficult and may be impossible without exploratory incision. The examination of the stomach contents has perhaps some value. When the test meal of Ewald and Boas shows an absence of free hydrochloric acid with Gunsburg's test and at the same develops lactic acid by Uffelmann's method of examination the indications are for cancer; yet prolonged non-malignant obstruction may cause such disease of the mucous membrane as to mislead the observer. In a considerable number of such examinations made for me by Dr. Christopher Graham the conclusions of Rosenheim have usually obtained, but these tests are far from reliable in character and at best are only confirmatory.

In two of my cases of obstruction from former ulceration the cicatricial mass could be plainly felt through the abdominal walls, so much so as to lead to a fear of malignant tumor.

After all, the chief factors in the differential diagnosis will be obtained from a careful examination into the personal history of the patient, especially as to previous ulceration and from the length of time the obstruction has existed. In this respect the occasional cases wherein the scar tissue of previous ulceration has degenerated into malignancy are of interest.

I wish to call attention to the significance of enlarged glands in the greater and lesser omenta as evidence of malignancy.

I have three times seen enlarged glands having all the appearance of malignant disease in non-malignant pyloric obstruction, evidently due to chronic sepsis from the absorption into the lymphatics of decomposing stomach contents.

Fenger speaks of this septic glandular enlargement about the head of the pancreas in his writing on "The Floating Stone in the Common Duct," as nowise malignant. I have found it in one case in the axilla in a non-malignant tumor of the breast and in the deep lymphatics in a case of sloughing uterine fibroids.

Bull says that 50 per cent. of pyloric cancer cases die of starvation before glandular infection takes place.

Maylard, in his work on "The Surgery of the Alimentary Canal," speaks of the large fibrous stricture of the pylorus as having only fibrous structure, but says that if epithelial elements be found in the enlarged glands malignancy is established. I think that the accuracy of statements as to the absolute malignancy of any case in which the proof is enlarged glands, which have not been microscopically examined, can be questioned.

OPERATIONS FOR THE RELIEF OF PYLORIC OBSTRUCTION

The median abdominal incision between the ensiform cartilage and the umbilicus has proved to be the most satisfactory in giving easy access to the field of operation. This can be enlarged by a transverse cut across the rectus muscle if necessary for free exposure.

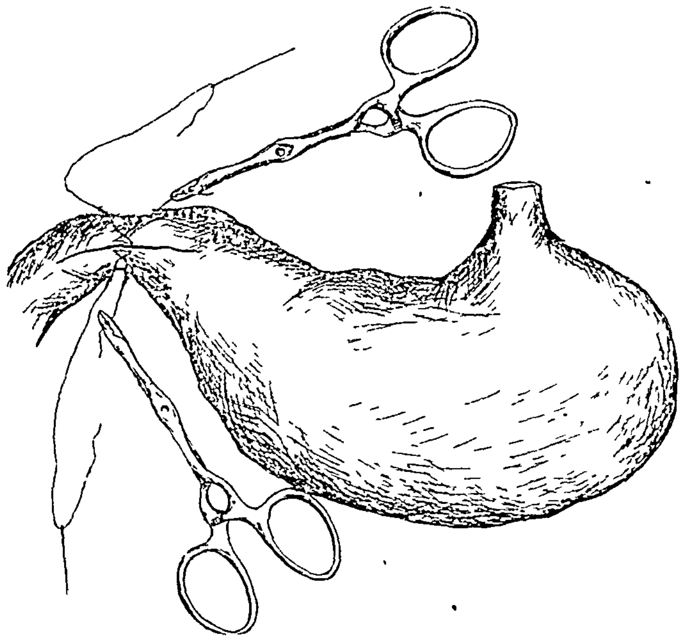

FIG. 1 shows the manner in which the first two stitches are applied. The forceps serve as retractors to hold the wound apart as shown in Fig. 2. These stitches are inserted before the incision is made.

Pyloroplasty, devised by Heineke and Mikulicz, is the operation of choice and in narrow strictures is easy and certain in its results. As much of the incision as possible should be in the healthy rather than the scar tissue, as the latter is stiff and does not nicely coapt and has the disadvantage of all scar tissue that necrosis is apt to be the result of the suture pressure. If the contracted portion is very long the duodenum can be folded or knuckled upon the stomach after the *adossement* method of the French authors. This latter plan worked admirably in the second operation on my fifth case. As pyloroplasty can not be readily performed in severe cases in which the scar tissue is very extensive or the pylorus bound down by adhesions to a degree which renders the operation hazardous, the mortality should not be great—about 10 per cent. Out of five cases I was able to do pyloroplasty in only two.

Gastrorrhapy, introduced by Bircher, may be a good operation in valve formation, but cases which are suitable to this procedure could be relieved by pyloroplasty.

Loreta's operation of divulsion has a mortality of 40 per cent. and fails in a large proportion of the cases, making a primary recovery to yield a permanent cure. Greig Smith, however, believes that it has a field in the large fibrous form of obstruction.

Pylorectomy will seldom be done for non-malignant stricture. I can understand how a surgeon could commence a pyloroplasty and finding this method unsuitable be forced to make a pylorectomy as the only way out of the difficulty, but the mortality of 50 per cent. is too high when contrasted with other methods of relief for general adoption. Weir, Meyer and others have done the operation successfully in this class of cases.

Gastro-enterostomy for non-malignant disease is an operation of expediency and not of choice. Circumstances often compel its use, however, as extensive contracture of the pylorus or the presence of tissue unsuitable for the security of suture union.

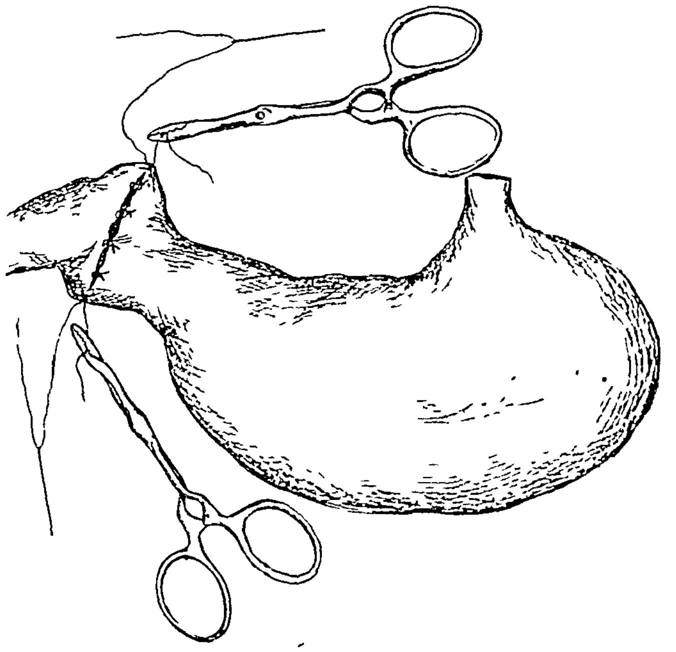

FIG. 2 shows the wound drawn transversely with a few interrupted sutures in place.

Inaccessibility of the field of operation, by reason of the presence of dense adhesions to important structures, is also an important indication. For one or more of these reasons, three of my five cases were relieved by gastro-enterostomy.

This operation by the suture methods, according to McGill, gives about 50 per cent. mortality and, with mechanical aids, about 23 per cent. The best mechanical device is, undoubtedly, the Murphy button. The greatest drawback to its use is the liability of the button dropping backward into the stomach upon separation. This happened in three out of eight gastro-enterostomies which I have made by its use. A year ago I suggested the tying of a string to the intestinal side of the button with the end in a double bow knot eight inches away, thinking that intestinal action at that distance from the site of the adhesions would act as a kite tail guide or tractor. In three cases the action was admirable. In a fourth case, I regret to say, the button had not appeared when the patient left the hospital and I presume it is in the stomach.

Great care should be exercised to secure the jejunum at its origin and form a coil as close as possible to the proximal end. Rockwitz says that the union should be made so that the intestinal and gastric peristalsis will be in the same direction to prevent impaction of the unused portion of the bowel. Braun advises entero-anastomosis to empty the duodenum more perfectly, and Kocher makes a right-angled attachment of the bowel to the stomach in order that gravity may aid the downward passage of the gastric contents. In all operations in this region the omentum can be readily fastened with a few sutures in such a position as to add greatly to the security of union. The unequal thickness of the stomach and intestine is a source of weakness in this operation.

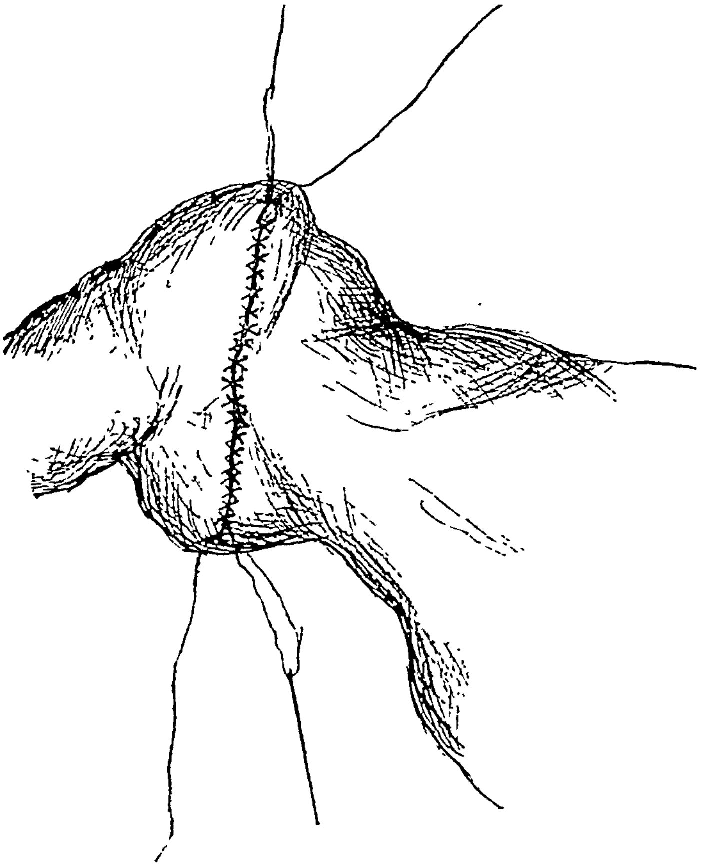

Fig. 3 shows the wound as closed by two rows of continuous Lembert sutures by means of the needles and threads used in the original sutures, the unthreaded end of the sutures having served as retractors as well as for the purpose of indicating the extent of the suturing necessary.

It should be borne in mind that a stomach with a normal capacity of three pints dilated to two or three times this extent at the time of operation, will certainly contract after relief of the obstruction, and that this contraction will effect the opening and correspondingly reduce its size to the same extent, and that such harmful contraction may not necessarily be due to the scar tissue forming the margins of the fistula. In this lies the uncertainty of gastro-enterostomy as a permanent opening.

Taking all of these facts into consideration, the suture method of Wolfler offers the fewest objections, as the opening can be of sufficient length to provide for future contraction and, with the improving technique of modern methods of suturing, the mortality will steadily diminish.

In operations on the stomach the emptying of this viscus should be carefully attended to previous to operation, to prevent contamination of the wound by escaping contents. A preliminary hypodermic of morphia with chloroform anesthesia has, in our hands, best controlled the tendency to retching so annoying in operations of this character. The after-treatment has been simple; morphia, if needed, to prevent peristalsis, and rectal feeding for three or four days, with strychnia hypodermically and stimulants per rectum as needed.

Case 1.—Stricture and valve formation. Pylorplasty.—M. M., male, aged 46, American, admitted to St. Mary's Hospital Jan. 10, 1895, with a history of gastric symptoms extending over a period of seven years. For the past two years he has vomited large quantities of partially digested or decomposing food, once or twice in twenty-four hours. He has grown weaker and lost about one hundred pounds in weight. Early in his illness he vomited blood a few times and suffered severe pain after taking food.

Physical examination.—Patient very much emaciated, heart's action feeble, with dilatation of the right ventricle. With the stomach-tube a large quantity of gastric contents was removed. Dilating the stomach with air, it was found to extend downward and to the left, to a point on a line with the anterior superior spine of the ilium. The pylorus was plainly felt on a level with, and to the right of, the umbilicus. Free hydrochloric acid was present in the test meal.

Operation.—Jan. 13, 1895. A small cicatrix was found on the anterior wall of the pylorus and from this a band encircled the pylorus producing a stenosis of about the caliber of a goose-quill. The sagging of the stomach was very marked, producing a *kinking or valve formation just at the stenosed area.* Enlarged glands were found in the mesentery, having the usual appearance of malignant disease. Pyloroplasty was done and the patient discharged February 15, cured. When seen six months later he had gained seventy pounds in weight and was doing his work on a farm.

Case 2.—Cicatricial stenosis. Gastro-enterostomy.—W. G., male, aged 53, German, admitted to St. Mary's Hospital May 26, 1896, with a history of ulcer of the stomach which had caused severe trouble for nine years. During this time he had been unable to work and was more or less constantly under treatment. For three years he had been unable to take solid food and at intervals of from eighteen to thirty hours vomited up *great quantities of material from his stomach.*

Physical examination.—Patient extremely emaciated and so weak as to be unable to walk without assistance. On dilating the stomach with air, it filled almost the whole of the left side of the abdomen. Examinations of stomach contents were contradictory and uncertain. To the right of the umbilicus a thickened area amounting almost to a tumor, could be felt.

Operation.—May 29. A very extensive board like cicatrix was found on the lesser curvature of the stomach and extending into the pyloric region. The strictured area was extensive, bound down by dense adhesions, and showed practically no tissue which would be safe to suture. Gastro-enterostomy was done with a Murphy button and string guide. Button passed on the thirteenth day; patient discharged June 19. When seen two months later he had gained thirty pounds in weight and was completely relieved of his trouble. When seen last (ten months after the operation) patient looked fat and well, but exhibited some symptoms of possible contraction of the *opening. Should these symptoms* become sufficiently marked I shall enlarge the gastro enterostomy opening, by an operation similar to pyloroplasty.

Case 3.—Cicatricial stenosis. Gastro-enterostomy.—Mrs. J. E., aged 55, Irish, admitted to St. Mary's Hospital July 6, 1896, with a history of chronic stomach trouble extending over a period of fifteen years. She had been unable to eat solid food for several years, and vomited large quantities once or twice in twenty-four hours.

Physical examination.—An enlargement felt to the right of the umbilicus. The abdomen protuberant and distended with gas. On examination this distention found to be due to an enormously dilated stomach. Examination of stomach contents shows free hydrochloric acid, but the tests were not very satisfactory. Patient very much emaciated.

Operation.—July 10, 1896. An extensive cicatrix found on the lesser curvature and in the *pyloric region.* The pylorus was contracted extensively and felt like cartilage. Enlarged glands were found in the omentum. Extensive adhesions rendered the field inaccessible, and the stiffness and extent of the stenosis made gastro-enterostomy expedient. This was readily done with the Murphy button. Imperfect preliminary removal of gastric contents made the operation difficult on account of escaping fluids after the stomach was opened. Uneventful recovery with rapid gain in both strength and weight.

Case 4.—Cicatricial stricture. Pyloroplasty.—(Three months after *adossement* for recontraction.) M. St. G., aged 50, Irish, admitted to St. Mary's Hospital Jan. 18, 1897, with a history of chronic gastric disease for twenty years. At times there would be complete relief of symptoms for some months, until about three years ago, since which time he has been in constant distress. He is unable to eat solid food and for a year has vomited a large percentage of the food taken. *Examination.* An emaciated man with a greatly dilated stomach which contained much of the food taken twenty-four hours before. Test meals show free hydrochloric acid. *Operation*, Jan. 21, 1897. A pyloric obstruction due to stricture, having its origin in an ulcer. Adhesions to the liver and gall bladder rendered elevation into the wound difficult. Pyloroplasty was done, some of the sutures being necessarily placed in the scar tissue. Patient discharged in good condition February 15. When seen April 1 he had gained twenty-five pounds in weight and said he could eat anything.

April 15. Was readmitted to hospital suffering from frequent vomiting and symptoms of acute obstruction at the pylorus, which had come on suddenly ten days previously.

April 16. The abdomen was opened in the middle line and as the pyloric mass lay to the right, the rectus muscle on this side was cut across just above the umbilicus, giving free exposure. Adhesions to the gall bladder and liver rendered inspection of the strictured area a matter of great difficulty and during the separation the pylorus at the seat of the stricture was opened widely, one wall being composed of the liver. It could now be seen that the sutures in the scar tissue had given way and adhesions to the liver had prevented leakage at the time, but these adhesions had been largely responsible for the recontraction. A long incision was made with its center at the opening in pylorus and the stomach folded over the nearly immovable duodenum after the fashion of *adossement* as described by Pilcher in his able article on "Fecal Fistula" in the Dennis System of Surgery. Over this the neighboring tissues were carefully drawn. The patient made an uninterrupted recovery.

Case 5.—Stricture and valve formation. Gastro-enterostomy.—B. K., male, aged 44, German, admitted to St. Mary's Hospital March 22, 1897, with a history of stomach trouble for five years during which time he had lost eighty pounds in weight. He does not vomit but for three years has used a stomach tube and removes by this means a large quantity of partially digested food from the stomach once or twice a day. *Examination.* On distending the stomach with air it fills the whole left side of the abdomen and extends across into the right hypochondrium. Test meals show free hpdrochloric acid. *Operation*, March 22, 1897. Pylorus held high by a short gastro-hepatic omentum. A circular stricture and marked valve formation was made out. Enlarged glands were found in the omentum. The field of operation lay well under the liver, in a situation which precluded a safe suture operation. Gastro-enterostomy was done with a Murphy button and string guide. Button had not passed when patient left the hospital April 20, otherwise he had made an uninterrupted recovery with entire relief of symptoms and steady gain in weight and strength.

DISCUSSION.

Dr. J. M. Barton of Philadelphia—Undoubtedly many patients are perishing from unrecognized pyloric obstruction. As recently as March of this year there was an article in the *Medical Record* mentioning the death of a patient from this condition. One reason for this is that the symptoms and history are misleading. The history should be a history of distinct gastric ulcer or a healed ulcer and then a history of obstruction, but such a history is quite rare. In hunting among the histories of reported cases but few of them have a distinct history of gastric ulcer, but symptoms are usually those of an ordinary dyspepsia. The headache, nausea, acid eructations after the taking of ordinary articles of food, and the sleeplessness and vomiting, which vomiting first occurs after meals and does not call attention to any obstructive symptoms. Ultimately these symptoms glide into symptoms of obstruction. We would expect, where there has been a long history of chronic catarrh, that the symptoms should be divided into two portions, those of obstruction and those associated with dyspepsia. If we operate, the symptoms of obstruction would be relieved, but the other symptoms would continue. I have been surprised to find that immediately after operation the symptoms would disappear. Where the patient is run down and continues to run down we should operate, but there are certain cases in which we should operate at all times. I agree with the reader of the paper as to technique. Owing to the contraction of the stomach the operation may not be of service. The cases in which I have performed dilatation have remained all right for many months, but I do not regard this operation as favorably as I used to. I found that some of my patients had been doing well before I operated on this case, but I have reason to believe that there is a latent obstruction in many cases. In cases where the patients are exhausted I think an operation will do very well. Where the whole ulcer is on one side of the pylorus and the folds of the mucous membrane have come together, if they be separated there is quite a possibility of the case getting well. I remember two cases, one eight years and the other two years ago. These patients had suffered many years, had lavage performed ten years ago and had symptoms of dyspepsia. After operation they made rapid recoveries and were able to eat and digest everything. One patient had no stomach symptoms for seventeen months after operation, but from that time he began to vomit and since then has vomited about ten times. He gained many pounds of flesh after operation but is now losing. His condition is such that if another operation is necessary I shall do pyloroplasty. With regard to the other case on which I operated the patient remained well without further symptoms and gained twenty-two pounds. She was able to act as station agent for four years, but recontraction has now occurred and she is losing weight. I intended to perform another operation but she declined to have it done.

Dr. Donald Maclean of Detroit—Dr. Mayo spoke of the diagnostic value of the microscope as deciding between benign and malignant growths. So far as my experience goes I have come to endorse the opinion, which I heard my old teacher express many years ago, that if you have a tumor you should cut it out, and if it does not come back it is benign, while if it does return it is malignant. I have submitted many tumors to histologists and I have had this sort of experience: "The tumor that you sent me is a round-celled sarcoma, exceedingly malignant and will soon kill your patient." The patient is still alive. On the other hand I have had just the opposite experience. I wish to ask whether there is a microscopic or a histologic standard established now by which we can judge whether a growth is malignant or benign; if so, I would like to know it. I have watched with the intense and critical observation of a father watching his son the work of my former pupil, Dr, Mayo, and I admire it very much indeed.

Dr. John B. Murphy of Chicago—Just because there is a tumor and some vomiting we are not justified in concluding that the case is one of carcinoma. Even if it kills the patient we are not justified. In a large percentage of cases occurring in people under 40 we find that this induration which is called a malignant tumor is not a carcinoma, and Dr. Mayo's paper brings this point out very well. In the class of cases where malignancy is suspected we must endeavor to make a positive diagnosis by an examination of the contents of the stomach, although even that is not sufficient to justify the diagnosis of carcinoma. The method of operating by Dr. Mayo is the best. Where a pyloroplasty is possible that is the operation to do. If a cicatrix is produced and this operation be rendered impossible we must do a gastro-enterostomy. The contraction will be in proportion to the amount of cicatricial tissue, to the entire size of the stomach and to the area of the sinus which is established. The first is the most important point. We find in anastomosis of the intestines that we have no great degree of cicatricial deposit and, therefore, less cicatricial contraction. The encouragement to operate on these cases in contrast to the very discouraging results produced in malignant disease is something to appreciate. The important point is to make a differential diagnosis. I believe that gastro-enterostomy in malignant disease is being relegated to the past as the mortality is enormous and the improvement very slight. Besides, patients who live through the operation are not benefited much. We have contractions of the stomach which make pyloroplasty impossible. If you examine a gastric ulcer at the end of the third week you will find a thickened mucous membrane in the neighborhood, and this cicatricial tissue is what you must endeavor to avoid in the operation of repair. An operation some distance from the pylorus is the more favorable I think.

Dr. Somberger of New York—It has been said that there is probably a contraction after the operation of gastro-enterostomy and I would like to ask if this has been proven. It seems to me that there is but little more probability of contraction there than in anastomosis of the bowel. The case I will refer to I saw in the Cook County Hospital and Dr. Murphy operated. It was an operation for fecal fistula. In opening the abdomen the lumen of the bowel was somewhat larger than normal instead of being smaller. If the atrophy caused by this button is such that we do not get contraction by anastomosis, why should we expect to find it?

Dr. A. J. Ochsner of Chicago—This Section is fortunate in receiving the reports of Dr. Mayo's cases, as he is situated where he can have an enormous amount of material. In many cases the cicatricial stenosis occurring in acute conditions has not been overcome and there is still a certain amount of irritation there which is the cause of considerable tenderness. Whenever there is tenderness over any point of the abdominal cavity the muscles over this point will contract and one will therefore find a distinct tumor in many cases, simply from the contraction of the muscle. In a number of instances I have seen tumors diagnosed absolutely, before the anesthetizing of the patient, which could not be distiguished after the muscles had been relaxed, notwithstanding that the technique of the examination was as perfect as possible. We should not therefore make a positive diagnosis of carcinoma.

SOME ADDITIONAL FACTS RELATING TO SKIN GRAFTING.

Read in the Section on Surgery and Anatomy at the Forty-eighth Annual Meeting of the American Medical Association held at Philadelphia, Pa., June 1-4, 1897.

BY Z. J. LUSK, M.D.
WARSAW, N. Y.

At the meeting of the New York State Medical Association, held Oct. 15 and 17, 1896, I read a paper the title of which was "The Vitality of Cutaneous Epithelium After Its Separation from the Body." Believing the subject of great surgical importance, and having additional testimony of interest, I decided to briefly submit my experience at this meeting.

The question of the "limit of vitality" of skin separated from the body has been the subject of a great deal of experimentation. The longest period of which I can find record is ninety-six hours, or four days.[1]

Experiments have been made[2] to ascertain the vitality of skin removed from the cadaver. Skin grafting has been successfully done with epidermis removed from the thigh six hours after death. Skin taken from amputated[3] limbs has been found to make good material. After numerous trials, thirty-six hours was found to be the limit of vitality. These experiments are of importance no farther than demonstrating that cutaneous epithelium possesses great vitality, but beyond this fact, they are of no practical value with "the limit of vitality" terminating at thirty-six or even ninety-six hours.

The cuticle or external layer of the skin removed so that it includes *only* the *epidermis* and *Malpighian* layer is the material used in skin grafting, and I have found that their viability depends not upon the low temperature nor confined air, but *solely* and *absolutely* upon the elimination of all moisture. This discovery renders the foregoing experiments of value, offering a source whence material could be obtained. Great care is, under these circumstances, necessary in separating the cuticle. I would prefer the epidermis obtained by vesication with cantharis to any other method, as the cuticle is more perfectly separated, requiring only from two to four hours, more often about three hours, drying quickly at ordinary temperature after its removal; and if kept free from moisture it will retain its vitality for an indefinite period, being always ready for use. I shall briefly refer to cases of which a full description can be found in various periodicals giving[4] technique, etc., considering in this paper only the dates of operating, illustrating length of time intervening between dates of removal of cuticle and their successful employment in skin-grafting.

An important change in the manner of applying grafts has been made which simplifies the operation and removes the cause which may have led to failure by applying the wrong surface of the graft. Grafts are now applied *dry* and *not moistened* before using on account of the curling up of the edges, making it difficult of planting, failure resulting from applying the wrong surface of graft to granulation. By the method above described, equally good results follow and this danger is avoided. The following cases are given without history or detail, but only to show the date of injury, skin-grafting, and of recovery.

Case 1.—E. S., saltlifter, injured by falling into a pan of boiling brine, Jan. 14, 1895. Nearly eight hundred square inches of raw granulating surface on body. I began skin-grafting February 16, using the dried epidermis, separated by vesication, adhering by one edge to body. He did nicely, whole surface healed and he was able to be up and about by April 1.

Case 2.—M. C., scalded Dec. 3, 1895. December 26 I began skin grafting, using dried skin which had been separated twenty-three days from cutis by vesication. At date of skin-grafting I removed several pieces of the dried skin, placed them between sterilized gauze and borated cotton, careful to note surface, tucked into envelope, labeled with date of separation from cutis, Dec. 3, 1895, and placed in office desk.

Case 3.—F. H., raw granulating surface two by two and one-half inches on dorsal surface of foot. Did skin-grafting with the dried skin which was removed as stated, Dec. 3, 1895; grafts took nicely and patient was up and about February 5.

Case 4.—J. O., switchman, hand crushed between drawheads April 2. Did skin-grafting May 15. There was a large granulating surface on dorsal aspect of right hand. Used same material heretofore described. Development of grafts was vigorous and rapid so that one month later the surface had a good substantial epithelium covering.

Case 5.—July 20, Mrs. S., widow, aged 52, carcinoma of left breast, which was atrophied and adherent, while nipple appeared as if pushed up; it was large and indurated. Commencing above the nipple there was an ulcerated surface extending upward and inward two and one-half inches and one and three-fourths inches. Commenced using mixed toxins with no perceptible change for three months, when she began to improve in general health, gained in flesh and spirits, and by January, 1897, the ulcerated surface appeared more like healthy granulation, and had slightly diminished in size.

On February 9, Dr. Mann assisting, I used the remainder of material separated now over one year, and skin-grafted. Did not disturb proximal dressing for ten days, at which date there was no discharge. Dressings were moistened with balsam, peru mixture and six days later all the dressings were removed. To my surprise grafts had taken well and were doing nicely, except at lower surface where no evidence of epithelium appeared; ten days later, except a surface one-fourth inch square, all was doing nicely and covered with skin, which at each examination appeared more vigorous. About the month of March she was seized with a severe attack of rheumatism and was unable to leave her bed. I was obliged to suspend treatment. Two weeks later, April 1, the lower granulating surface began to extend its boundaries, destroying the new skin.

The longest period that the cuticle has been made to live and grow after removal from the body was ninety-six hours, or four days. This was an experiment made by Georges Martin, who believed that the prolonged vitality was due to the low temperature and confined air at which it was kept. I am of the opinion that its vitality was due to its being dry, or so nearly so as to prevent molecular change.

The cases reported by me show that in case No. 1 the material used had been separated from the cutis forty-eight days. In No. 2 it was separated twenty-three days. In No. 3 the skin was taken from No. 2, separated by vesication from scalding, and sterilized on December 26, then covered with borated cotton and laid away in an office desk, when skin-grafting was done Jan. 12, 1896, forty days after separation from the cutis. No. 4 was with the same material, 164 days. No. 5 was the same as No. 3 and 4, grafts revitalized, showing as rapid and vigorous growth as in any of preceding cases, 418 days after its separation from cutis.

[4] Medical Record: Journal American Medical Association; International Journal of Surgery.

To conclude then this method should supersede all others because of the following facts:

1. The surgeon can always have an abundance of material ready for immediate use, and the artificial skin produced is more firm and elastic than that produced by any other method.
2. The cuticle when first removed should be sterilized, when it will soon become dry at ordinary temperature, care being taken to remove all folds or wrinkles and that it be kept entirely free from moisture.
3. The granulating surface should be thoroughly irrigated with warm normal salt or boric acid solution before applying grafts.
4. Grafts should not be moistened before being used, but should be dry, and great care should be taken that the proper surface be applied. Operator catching skin with common artery forceps, a piece can be clipped off one-twelfth inch wide and one inch in length, out of which twelve grafts should be made not more than one-half inch apart.
5. The grafted surface should be covered with sterilized gauze saturated with a mixture of balsam peru and castor oil, one drachm to one ounce, over which should be laid sterilized borated cotton, three to four layers.
6. Proximate dressing should not be disturbed under ten to fifteen days, unless pus is being formed, when it should be removed and carefully irrigated with boric acid solution, and new dressings applied.

DISCUSSION.

Dr. GEORGE M. STERNBERG of Washington—I would like to ask if Dr. Lusk ever used the skin from a blister produced by heat. It is very remarkable that the heat does not destroy the cuticle, and I think it would be important to determine the death point of the epithelial cells. I would suggest that if practicable some one might make this experiment.

Dr. R. H. SAYRE of New York—I am somewhat surprised at the vitality of living tissues exposed to dry hot air. In the treatment of chronic arthritis, in exposing joints to a high grade of air the skin will endure from 350 to 400 degrees F., and I did not suppose this possible. Some persons can not stand more than 180 to 220 degrees. It occasionally happens, however, that after the lapse of a few days you will find ulcerated spots on the skin which look like a blister. Apparently this intense heat will at certain spots cause sloughing of the tissues, which is very slow in regenerating.

Dr. THOMAS H. MANLEY of New York—I hope we do not understand Dr. Lusk to say that this species of grafting was recommended to supplant skin-grafting proper, as this is really epidermal grafting. I presume he intends this method for superficial destruction of the layers of the integument. He would not recommend it, I should think, in that class of cases where the skin is entirely swept away. This method is similar to the Thiersch method and the only questions that will arise are as to how durable it is and as to whether there is any tendency to the scar formation which is so common in the Thiersch method. In parts of the body covered by the garments, where there is not much motion, I can understand that the plan suggested by Dr. Lusk is probably better than any other. It is most extraordinary to conceive of the simplicity of it, and the fact that we are able to keep the tissues so long renders it one of the most valuable methods of skin-grafting that we have. How far can this layer of the epidermis supply this loss of skin is the point. In extensive injuries to limbs there are two important questions: First, what can we do in the destructiod of bone; and second, what can we do where there is not much destruction of bone, but there is much destruction of the skin. I would like to ask if, where there has been an extensive area of gangrene of the integument, this method would apply.

Dr. LUSK—Dr. Manley may be right, but his method would be called plastic surgery. In all the works that I have consulted skin grafting is the only term used. I do not know of any heat that will hurt the skin except the heat that destroys the entire skin, such as boiling in a salt solution. My own experience was with a man who had plunged head first into a bin containing boiling brine. Four weeks after the accident I decided to commence skin-grafting and it was successful in every way. Dr. Roswell Park saw it and paid me a very high compliment for the discovery. The legs, arms, and a part of the body were skinned, and from seven to eight hundred inches were necessary to do the operation. I soaked the material in a peroxid solution and then applied it. So far as cicatricial contraction is concerned there were only a few corrugated bands. There were two ulcers, due to a slough, which healed entirely.

DIAGNOSIS OF MINOR PHYSICAL INJURIES AND THEIR RELATION TO ACCIDENT INSURANCE ASSOCIATIONS (WITH ILLUSTRATIONS OF CASES).

Presented to the Section on Surgery and Anatomy, at the Forty-eighth Annual Meeting of the American Medical Association held at Philadelphia, June 1-4, 1897.

BY LISTON H. MONTGOMERY, M.D.
CHICAGO.

Accident insurance and personal injuries to policyholders, are subjects to which I have devoted some thought and attention during the past few years, and I am a staunch advocate of the former. As a rule, the reasonableness of its cost should commend itself to every worthy male adult subject who is eligible to avail himself of the privilege of procuring a certificate of membership in some one or more of the various substantial insurance associations throughout the country.

The business of accident insurance companies is mainly conducted by the secretary and a board of directors, and in the matter of claims, by the claims committee aided by the wisdom and advice of the surgeon, the medical director or medical examiner. The office that the surgeon fulfils is a most important one; one whose motive power and influence usually commands great respect from his business associates. To him is oftentimes referred questions that are more or less intricate on account of their not being understood by the board of directors or claims committee, and this, according to my experience, is much more frequently the case when, as the title of this paper suggests, the injuries appear to be trivial or insignificant in character, notwithstanding the report of the attending physician or surgeon would indicate that just the opposite is the case.

Personal injuries are as varied in kind, character and degree as the kaleidoscopic changes in a man's lifetime and the causes producing them are as innumerable as it is possible to imagine. It is not to be wondered at, therefore, if a scientific descriptive report of an injury to a patient by the attending physician should require additional explanation or elucidation by the company's surgeon. In other words, without the aid or advice of a company's medical representative, it would not be possible to adjust and dispose of all cases of bodily injury in a satisfactory manner, and diplomacy of an honorable character is necessary in some instances to achieve this much desired result.

The declaration or blank form of application which a person is required to fill out before a policy is issued, stating name in full, age, birth-place, residence, occupation, etc., to enable the board or proper officer to decide which class of risk the person shall be placed in, in most instances contains the following: That the policy-holder shall "live up to" or agree to abide by the constitution and by-laws of the association not obligating it to pay for injuries received or which may happen while the policy-holder is under the influence of intoxicating liquors or in consequence thereof; nor where there is no visible mark on his body; nor for intentional injuries inflicted by himself; not while engaged in violating the law; nor from voluntary or involuntary taking of poison or any contact with poisonous substances; nor death due to suicide, whether sane or insane, or due to mental infirmity, hernia, medical or surgical treatment (except amputation of a limb necessitated solely by injuries sustained in accident); and the acceptance of the certificate of membership further absolves the company from being made a party to legal proceedings upon the basis and provisions herein stated, and lastly, the "insured" further agrees that the company's surgeon shall be privileged to make a physical examination of his alleged injuries as often as such official may deem necessary. And yet in the face of all these, and perhaps additional declarations, the policy-holder not infrequently will assail the reputation of our best companies and threaten their extermination by instituting unwarranted legal proceedings, particularly in these days when, singularly enough, cases are known where learned judicial decisions have been handed down which, it appears to me, were either a perversion or a disregard of the contract.

I have selected a few out of the many cases that have been referred to me for examination or which have come under my surveillance during the past year, showing what basis the claimants had to recover indemnity and what some persons actually believed they were entitled to, due to an occurrence, mishap or whatever term one sees fit to name it, even to calling it an accident in all that this term implies, and in none of these cases was there a supicion of any motive of deception being practiced.

The subjoined cases are non-exaggerated instances of descriptive reports from claimants and from very excellent physicians, that I have been called upon to explain for adjustment during the past year, although I disclaim any intention of stating that they were not scientifically accurate so far as diagnosis was concerned.

Mr. D., a resident in one of the suburbs of Chicago, had the misfortune to get his levator labii superioris alæque nasi muscle lacerated by being thrown from his buggy, and as a result was totally disabled for six weeks. Upon visiting this gentleman and carefully reviewing the case, a satisfactory adjustment of ten days was agreed on, inasmuch as no cicatrix or permanent deformity remained.

It may not be devoid of interest to cite the following case for the Section to deliberate and decide whether the injury was occasioned or caused by violent, external and accidental means: A gentleman occupying a chair at his hotel, with his right leg over the left in practically an extended position, smoked and conversed with a fellow-traveler. On attempting to rise from his chair he was suddenly attacked with severe pain in his right knee and could not walk up stairs to his room. He admitted that he had not strained any of the ligaments about his joints nor otherwise injured himself, and claimed never to have had rheumatism; and yet he was totally disabled for a period of seventeen days. This gentleman having been the subject of a similar experience about six months previously I was requested to investigate his case. My diagnosis was "floating bodies in his right knee joint" and that he was not entitled to indemnity according to the rules of the association in which he was insured. He demurred at this and threatened to bring suit against the association. The result was the amount of his claim was paid and his policy was canceled. Recently this gentleman has had a similar attack, just as I expected he would.

Here is another illustration of a so-called personal injury and description of an accident as different from the preceding case as one can well imagine. A gentleman while stopping at a small city in Michigan in July, 1896, proceeded to call on his patrons. He was quite active during the day, as he subsequently stated, and concluded his day's business in apparently his usual excellent state of health. He rested over the Sabbath and attended services at one of the churches. Monday morning at about 7 o'clock, without exertion on his part, while he was arranging his toilet he suddenly began to expectorate blood. During the ensuing four days (up to the following Thursday evening) he experienced not less than five similar attacks of this kind. He returned to Chicago and did not resume traveling for four weeks. He subsequently filed a claim for this period, claiming that his loss of time and total disability was induced by his over-exertion (which he called an accident) on the Saturday previously, or thirty-six to forty hours prior to his first hemorrhage.

The following somewhat unusual case may be deemed of sufficient importance to chronicle in this report, as to the writer's mind it is unique as well as a singular illustration of how the unexpected might happen. A gentleman was ill with indigestion or he had some other form of temporary stomach difficulty. He was being treated by his physician and after three or four days, although attending to his usual vocation, he began to feel the physiologic toxic effects of the remedy he was taking and was obliged to remain at home for another week before complete convalescence was established. This gentleman filed a claim for this length of time, claiming that his total disability was the result purely and simply of an accident.

During the past winter my attention was called to a case of phlegmon or small abscess located under the chin of a gentleman and caused, as the claimant stated, by his barber cutting him while being shaved, when he had as a result, blood poisoning for ten days(?). Upon careful examination it was clearly proved that the gentleman had an inverted or ingrowing hair. A minute pustular eruption had formed, and when the barber had called the attention of his patron to this he was requested to remove the offending hair, as also to evacuate the drop of pus that had been secreted. This slight traumatism resulting in what the attending physician called "sepsis," was the cause of this claimant filing a claim for the above length of time.

Cases of trimming a corn, bunion, wart, etc., have come under my observation within the past year, wherein a form of septicemia resulting in apparent total disability lasting from one to three weeks supervened, and the insured filed their claims for these various periods.

On Monday, during one of the early fall months of last year, a gentleman while riding in a railway coach near Clinton, Iowa, was reading his newspaper, holding same in his left hand. Simultaneously he had his right hand resting on the back of the seat in front of him. Suddenly he experienced a stinging or pricking in the dorsum of the little finger of his right hand. He examined his finger, but saw nothing unusual. After vigorously rubbing the spot he again proceeded to read, but the stinging sensation remained unabated (at least for the time being). In a little while he had occasion to look over into the seat on the back of which his hand had previously been resting when he noticed a black spider. He naturally concluded that the spider had stung him, and killed it. He continued to attend to his business until the following Monday morning, one week having elapsed, when his hand began to show evidence of infection. The result was he was totally disabled for ten days.

Cases of lame back due to a strain of some of the tissues about this portion of the body are probably as frequently met with as any other form of bodily injury, and are often puzzling in character, mainly because there is nothing to indicate this, discoloration being absent. No zones of anesthesia, areas of tenderness, hyperesthesia, edema nor other signs of inflammation are present; no constitutional disturbance is present, and other subjective symptoms are normal. Frequently a congeries of symptoms arise, complex in their nature, difficult of diagnosis as well as prognosis and probable duration of disability. Only last month I was summoned to a city some one hundred and sixty-five miles from Chicago to visit a case of this kind, due to an accident which occurred January 4, and was supposed at the time to be of a most trivial character. This case had during the past five months developed through reflex disturbances and other causes of a cognate character, all manner of complications or sequelæ of a most distressing kind, in which may be enumerated dysuria and tenesmus, pleuritic complications, most obstinate constipation, gastric disturbances, paralysis, as well as other cerebral and cerebro-spinal symptoms of the meninges and cord; so that for weeks the patient's life was despaired of. In other words, a diffused traumatic neurosis had followed an apparently slight physical injury.

A case was quite recently referred to me where a sparrow was flying through the air and darted toward a gentleman's face. Its bill came in contact with his left eye resulting in a puncture of the iris. This accident was a most singular one and the traumatism has resulted in multiple neuritis, difficult to prognosticate what the final result may be.

A gentleman, 28 years of age, who had a longstanding hernia and for which he wore a truss, was carrying a box weighing between forty and fifty pounds in an unguarded moment when he omitted to have his truss adjusted. Strangulation ensued. The case was treated during the first few days by taxis, applications of hot fomentations and anodynes, with negative results, and it was found necessary to perform an operation for the radical cure of his malady. He was totally disabled for weeks and filed his claim for this period. The result in this case was a decision that his was not a case for indemnity according to the by-laws of the association in which the gentleman was insured.

Bicycle accidents.—A word in this connection regarding the so-called bicycle accidents, wherein abrasions and contusions of the cuticle and injuries to various parts of the body may occur to a greater or a minor degree. In this connection, I have seen the following case: A cyclist fell from his wheel and sustained a trivial bruise or contusion over the region of the appendix vermiformis. In five or six days active symptoms of the inflammation of the appendix supervened and the gentleman was totally disabled for fifteen days. Naturally enough he attributed his disability to the violent manner in which he was thrown from his wheel, whereas it seemed to me, technically and correctly speaking, that this was coincident or incident to it, as at the time of his mishap the weather was inclement and there was a reasonable doubt that dampness and exposure and even other causes contributed to his attack. Suppose this man had died and an autopsy failed to reveal a foreign body in his vermiform appendix, the chances are that it would have cost the accident association in which he was insured $5,000.

At Oregon, Ill., on March 14, 1897, a gentleman was hunting. The weather was inclement and he wore a pair of rubber boots larger than he was accustomed to, with the result that he produced a minute abrasion on the fourth toe of his right foot. It was proved that the boots he wore were defective and his feet became very damp. What was diagnosed by the attending physician as septicemia supervened and the claimant filed a claim for four weeks' indemnity for total disability, accompanied by an affidavit from his physician, who stated that the abrasion and consequent infection was due to an accident. The claim was rejected.

The subjoined case explains itself as being directly opposite to the foregoing, which I did not personally investigate, though my attention was called to it on account of its recent occurrence and for other reasons. I refer to the noted "sore toe case" wherein it was decided that an accident insurance policy must be paid where death resulted from wearing a tight shoe. A judge of the United States Circuit Court sitting at St. Louis handed down a decision in the case of Smith v. The Western Commercial Travelers' Association (Dec. 16, 1896), giving the benficiary a judgment for $2,165. The plaintiff was the beneficiary and widow of a member of this association holding a policy for $5,000, payable in the event of death by "external violent accidental means." Up to August, 1895, Mr. Smith appeared to have been an exceptionally strong healthy man. About this time he commenced to "break in" a new pair of shoes. The friction caused an abrasion, although, from evidence that he gave, reasonable attention was paid to the inflamed surface; it grew worse, and by September septicemia supervened, and on October 3 he died from the latter cause. According to the learned judge, as the decision was handed down, death was the direct abrasion of the toe caused by the tight shoe, and the conclusion arrived at was that death was occasioned by immediate external, violent and accidental means within the true meaning of the policy, and why a judgment for $2,165 was given instead of for the full amount does not seem to have been explained.

Rules on mosquito bite.—The following is the latest ruling regarding this little animal, handed down by a Frankfort (Ky.) court May 22: The court of appeals in the case of Mrs. S. O. v. The United Stated Mutual

Accident Association, decided that the lower court was wrong and that she was entitled to $5,000, the amount of an accident policy carried by her husband, who died from a mosquito bite which he received while he was asleep; the court holding it to be an accident in the meaning of the law.

The last case that I desire to present may not be regarded as a minor physical injury in the strict sense that is usually implied, as it was a fracture of the left fibula and at the time of its occurrence and for upward of three weeks afterward no one, not even the patient nor his physician, believed but what a perfect cure would follow. On March 4, 1897, a gentlemen, 60 years of age, fell on a slippery sidewalk and fractured his left fibula about three inches above the ankle. It was not a Pott's fracture, and a dislocation or subluxation of the tibia at the ankle joint occurred. This gentleman lived ninety miles from Chicago, whither he was removed the day following his mishap. The fracture was reduced, a substantial plaster-of-paris dressing was applied and the patient progressed favorably until Sunday evening, March 28, twenty-four days after the accident. At about 8 o'clock he was suddenly seized with dyspnea, cold perspiration, flickering pulse, anxious facies; indeed, with all the symptoms of speedy dissolution. The attending physician, who had not deemed it necessary to visit his patient during the preceding three or four days, was summoned and found his patient in collapse. So rapid was his decline that death ensued at 2 o'clock the morning of the 29th. Here is a case where an unlooked-for fatal result occurred to a man who had always been known to be well and healthful, correct in his habits and who, on the Sunday preceding his death, sat up for five or six hours, dressed, reading and conversing with members of his family. He also ate a hearty noonday meal and luncheon at tea time. There was no neurotic or rheumatic history in the case nor anything to lead one to suspect that any pathologic change had occurred in his system, and yet, without apparent cause, this man rapidly sank and died in the manner I have just described. News of his death was telegraphed to the accident association of which I am chief medical examiner, and I visited the man's home and decided that an autopsy was necessary to decide the cause of death. This was held the next morning in the presence of six physicians, the attorney for the beneficiary, the undertaker and the secretary of the association which I represented. Every organ was found to be normal, including bladder, liver, kidneys, suprarenal capsules, mesentery, stomach, gall bladder, intestines, vermiform appendix, lungs, pulmonary vessels, the cavæ, the coronary arteries, the aorta, right and left sides of the heart, including the valves and columnæ carneæ and other structures of the heart: however, when investigating the left ventricle, a white fibrinous clot six inches in length was discovered. This extended up through the ascending aorta, and it was decided by the medical gentlemen present that the cause of death was due to the antemortem clot. No infarct nor embolus within the pulmonary tissue or pulmonary vessels could be detected. We were positive that the clot was antemortem, as it adhered to the papillæ of the tissues of the left ventricle. There was no lesion or anything else pathologic about the heart, except a weakened, flabby and softened condition of the cordæ tendinæ. What relation or connection this form of injury could possibly bear toward the surgical pathologic condition found in the heart of this man, I confess I am not able to explain, unless it was due to the weakened condition of the cordæ tendinæ. The case is now pending an adjustment.

I desire to refer again to so-called floating bodies in joints. Halstead (*Annals of Surgery*, September, 1895) draws the following conclusions:

1. That the etiology of some of these bodies is not fully understood, but that the condition described by König under the name of osteochondritis desiccans explains the most of those that are otherwise found in normal joints.
2. That few, if any, are the direct result of violence.
3. That the most pronounced symptom is the sudden onset of severe pain in the joint with locking of the joint, usually in a nearly extended position; this being followed by acute inflammatory processes in the joint involved.
4. That the lengthening of the femur (in movable bodies in the knee) may occur as a result of irritation produced by the pressure of these bodies.
5. That the only treatment for this condition is their removal by direct incision, preferably under cocain anesthesia, as soon as the diagnosis is made.

In conclusion.—In submitting this imperfect report I disclaim any intention of leaving the impression that in any of these cases was there existing collusion between patient and physician, or any motive of deceptive thought by any of the claimants or on the part of the attending physicians, but I simply wish to point out a few possible errors in judgment that creep in or are likely to do so in slight physical injuries where an accident policy is carried.

DISCUSSION.

Dr. Reyburn of Washington, D. C.—I would like to say a word with regard to physicians who have suffered from septic infection. I had a confinement case and soon afterward developed symptoms of infection which disabled me for seven weeks. The accident insurance company refused remuneration, and I would ask what is the use of physicians insuring in these companies unless they can be paid for expenses of this kind. I would like to ask if accident insurance companies can not be made to pay for accidents of this kind.

Dr. William T. Bishop of Harrisburg, Pa.—I have had experience both ways. One of the most essential difficulties as to an accident policy is the fact that when you eliminate the number of exceptions there is practically no risk left on their part, and they will beat you in every way. There is in many cases an exception in which a medical man can not antagonize the medical men of the country. The company will often find a traumatism which does not exist. We want to reconstruct insurance companies and ourselves. Cases of septic infection should certainly be included, and we should not waste our money in paying for insurance policies if this can not be done. If the medical man of the company was treated more fairly in many cases by medical men it would be beneficial.

Dr. Reginald H. Sayre of New York—My experience has been similar to that of Dr. Reyburn. When taking out my policy I asked if I could recover if I should break my arm or leg, and the agent told me that would not count at all as the clause would not operate in such a case. Some time after I broke my thumb and was prevented from operating for several weeks. I suffered pecuniary loss and put in my claim for damages against the company. I received a check for the amount with a letter stating that the company did not wish to insure me in the future. It is true, these companies do not pay claims if they can avoid it.

Dr. W. W. Keen of Philadelphia—I agree that insurance companies should be liable for septic infection during operations. It is as much an accident as falling from a bicycle, and even more so sometimes by sacrificing life. I have always insisted when taking out a policy that it should cover all cases of septic infection. Sometimes the companies demand a higher rate and I have paid it, although I saw no reason why I should pay it. However, we must be just with the companies and not expect them to do more than they agree.

Some of their policies state that there must be a total disability and they base their rates on this fact. In a case of partial disability we should not expect them to pay the full amount or to hold them liable. We must be just both ways, but I think they are unjust to physicians, and especially surgeons, in demanding an extra rate.

Dr. I. N. QUIMBY—I have been insured in accident companies for some time and I know of one or two New York companies who pay for partial disability. One company paid me one-half the weekly allowance. They make the claim that the physician is guilty of contributory negligence, and this they have no right to do. When they make this claim you can do nothing, for it is practically dishonesty.

Dr. ALLEN of New York City—This question of septic infection should be more understood by the physician. I remember a case of a physician dying from septic poisoning, and the question arose whether or not he had an abrasion on his finger when he operated. There was some doubt about this, but he may have had a hang-nail on this finger; and the company would not pay. There was considerable trouble on this point and finally the man was found to have had an abrasion. If it had not been for this fact the company would have paid for the accident. They have a number of fine printed clauses which we do not always read and are therefore not aware of.

Dr. DWIGHT—I am not connected with any accident company, but I do not see why the company should pay in a case of infection. The septic poisoning might just as well have been the result of some internal disturbance and may have resulted from within the mouth. There may be no relationship between the injury and the result, and may not have been due to the operation at all. This matter should be settled in some way satisfactory to the company and the insured.

Dr. L. H. MONTGOMERY—The circumstances alter the case. If there is nothing stated in the policy regarding sepsis, perhaps some companies would succeed in avoiding paying. I know of no company who will not pay indemnity for any accident that results in blood poisoning unless there is a clause inserted against it.

STATE MEDICINE TO THE PRESENT TIME.

Presented to the Section on State Medicine, at the Forty-eighth Annual Meeting of the American Medical Association at Philadelphia, Pa., June 1-4, 1897.

BY FRANKLIN STAPLES, M.D.
WINONA, MINN.

State Medicine, the department of science and government pertaining to public sanitation and public health, is a development of modern times, is largely a product of the civilization of the latter half of the present century; yet in its rapid extension it has become nearly universal, has an important place in the state enactments of nearly all nations. Physicians were recognized by law in very early times, and were provided for in the armies and at the courts of kings. In the Middle Ages something was known of medical jurisprudence. Legal medicine is said to have been founded by one Paolo Zachias of Rome, at the beginning of the seventeenth century. What is mentioned as state medicine, taught in the German universities in the eighteenth century, was but the forensic medicine of the times relating to laws in medical jurisprudence. The establishment of state medicine in all countries follows much later than the development of medicine and surgery and the making of physicians.

The principle declared by the fathers of our nation, that life, liberty and the pursuit of happiness are the inalienable rights of all people, and the acknowledged fact that it is the province of government to ensure these rights by suitable laws, are at the foundation of what now exists in this department, as in others pertaining to the welfare of the human race.

The character of the advancement in state medicine and the standards of excellence attained are noticed as indicating the intelligence, culture and good government of a state or country. Greater difficulty has been experienced in some of our States than in others in the establishment of sanitation by law; but for contrasts in sanitary affairs and conditions, the differences between countries must be observed. The difference in government and a reason for want of progress in civilization appear in the following, which is mentioned as an illustrative case: France not long since proposed a reciprocity with Turkey for interchange of vital statistics. Blanks were sent to the heads of departments. One of these went to the Moslem magistrate of old Damascus. The information furnished by the Turk is as follows: 1. "What is the death rate of your city?" *Answer.*—"In Damascus every one must die at the command of Allah! Some die young and some die old, but every one must die." 2. "What is the rate of births?" *Answer.*—"I can not answer this question. Allah knows all that." 3. "How is the supply of drinking water?" *Answer.*—"Since time immemorial nobody died for want of water in the city of Damascus." Concerning the general sanitary condition, the learned magistrate's answer was, "Since Allah sent his prophet, Mohammed, into this world with fire and sword, things are better." This much for a defective civilization of antiquity continuing in modern times. Fortunately, not many such governments have survived to the present time.

The following concerning progress among our States is suggestive of important facts: In a certain State of the interior, the State Board of Health appealed to the legislature for the passage of a better State sanitary law, and addressed to the members a circular letter, from which the following are extracts: "There is annually lost in this State not less than $5,000,000 through unnecessary disease and unnecessary death." The State is urged to save this great annual loss by better sanitary laws properly executed. The circular, in its just and reasonable appeal, further gives the case as follows: "The major portion of the bill proposed has been drawn from the laws of Massachusetts, New York, Michigan and Pennsylvania. These States, through their health laws, have gained much wealth and power. . . . The old law of our State is not up-to-date. It does not take account of recent discoveries in sanitary science, and fails to meet many conditions necessary to accomplish thorough health work. It may be likened to an old, wheezy engine that coughs and groans as it hauls its insignificant load." It is supposed that the legislature came to time with the new law.

The question of first rank among the nations in the matter of state sanitation may be considered. State medicine in England is a little older than is that of the United States; the whole time of the former being a little more and the latter a little less than half a century. Moreover, the English system has an advantage, in that in its management and support it is national rather than local.

The English parliament became informed and interested in the subject of national sanitary improvement in 1844. Laws were passed, and state medicine became and has continued to be an important feature in the government. In the United States, state medicine properly began in the State of Massachusetts with the formation of the State Board of Health in 1869. Eight years were required for the making of the first ten boards in as many States. At the present time there are thirty-eight State boards in the forty-six

States. Laws governing these boards have been largely copied by the different States, but a want of complete uniformity in function and authority among all the States is found to exist. A more complete uniformity and its attendant advantages to the States, would result from the establishment of a National department of public health, with National enactments to which all State laws should conform. State medicine, in many of its features and functions, is necessarily National, and moreover has important relations with matters of international belonging and character. Regulations concerning seaboard notification of contagious diseases, State and seacoast quarantine, sanitation pertaining to railway transportation and laws pertaining to the pollution of streams illustrate, in small part, the many ways in which National rather than State legislation is demanded. A movement is on hand to secure, by international reciprocity, the inspection and detention by quarantine of infected vessels and passengers before the sailing, rather than before the landing on either side of the ocean. A vessel on an ocean voyage, laden with infection of disease, has come to be regarded as too much of a culture-tube for infection, to be a profitable importation to any country.

There has been a varied history in this country concerning the National supervision and control of quarantine, and concerning all that pertains to the general government in matters of public health. National legislation began in 1878. An act of Congress, approved April 29 of that year, conferred upon the Marine-Hospital Service certain duties, principally relating to quarantine against the introduction of contagious diseases into the country. The same year an epidemic of yellow fever occurred. This called general attention to the subject of a National health organization. Epidemics and the coming of pestilence have been useful in causing reforms and bringing to pass important preventive measures. It requires an occasional prevalence of smallpox to make the sale of vaccine virus profitable. At that early day i the history of its good work the American Public ealth Association, by its active interest, helped to ecure legislation. A bill was passed by Congress, and approved March 3, 1879, which created a National Board of Health. This Board consisted of seven members appointed by the President and confirmed by the Senate, and four members *ex officio*, one from each of the following departments: Medical Departments of the Army and Navy, the Marine-Hospital Service and the Department of Justice.

The Board organized, assigned work in different departments to different members. employed experts to make special investigations and studied conditions along the following lines and others: The collection of information with regard to sanitary condition of cities and towns; on methods of determining the character of organic matter in the air; on the adulteration of food and drugs; on the diseases of food-producing animals; on the flow of sewers in relation to their size and gradients; on the hygiene of the mercantile marine; on the influence of various soils upon sanitation. This was the undertaking, by the government, of practical sanitary work which, having been carried on in different States, has afforded splendid results, the benefit of which the Nation enjoys today.

In the first annual report of the National Board, together with the records of other important work, appears the following: The work of the Havana yellow fever commission; sanitary survey of Memphis, Tenn.; report of diphtheria in northern Vermont; sanitary regulations for quarantine stations, vessels, railroads, etc.

The following was written concerning the National Board in the second year of its existence:[1] "The experience of that season was of immense importance in the future efforts to protect the country from foreign pestilence. It was demonstrated, 1, that National, State and local health authorities could usefully coöperate in suppressing an epidemic, and in preventing its spread from one State into another; 2, that travel and commerce need not be seriously interfered with, provided a vigilant sanitary inspection is maintained." Other conclusions appeared concerning sanitary means for the suppression of yellow fever, in which work the efforts of the Board were largely directed at this time.

The further history of the National Board of Health is in brief as follows: In 1881 there began to be in Congress manifestations of hostility to the Board on the part of some members of the subcommittee on appropriations. The funds of the Board were diminished and made conditional. The end of the work of the Board was now approaching. The final sentence of death was pronounced when, concerning the appropriation made for the use of the Board in 1882, which was called the "epidemic fund," the President informed the Board that he had transferred his "discretion" in the use of the "fund" to the Secretary of the Treasury. An enactment had authorized such a transfer. Transactions of this kind and the necessary results of the same, led a writer in the *Sanitarian* to suggest that the country was in need of *political drainage* as a general sanitary measure.

Since the departure of the National Board, National control has been in the hands of the Marine-Hospital Service in the department of the Treasury. All matters of quarantine are in charge of this office. Reports, foreign and domestic, are made to it, including vital statistics, disease prevalence and weather reports. A weekly bulletin of public health reports is issued and distributed regularly to the health officers throughout the country. There can be no objection to what has been the service of this department in the scope of its work, but it is believed that the great enlargement of sanitary work of late years, and its extension into new fields because of modern discoveries and advances in science, call for the establishment of a National department of state medicine, which shall have for its subdivisions the different State organizations as well as that pertaining to the coast, the ocean and to foreign relations.

It has required less time to advance State medicine, to enact and maintain sanitary laws, and to find support for the same in the State, than it has in the Nation. Political obstacles in the way of what is mainly for the advantage of the whole people, are more and greater in the great country than in the smaller states, and time is required to meet the unworthy, conflicting interests in the larger field; but what is demanded in the majority of the States must eventually obtain in the Nation. There is a community of interests in what pertains to the lives as well as to the property in the common wealth of the Nation.

It is now asked that a National department of public health be established, with a secretary of the department, rather than a National board. A committee of the first and second Pan-American Congresses, held in 1893 and 1896, has urged National legislation for the establishment of this department. The AMERICAN MEDICAL ASSOCIATION, through an able committee of sanitarians, has caused a complete bill for this establishment to be placed before Congress. This bill carefully defines the province and duties of the proposed department, and covers the ground of legitimate sanitary work to be undertaken by the general government at the present time. It would seem that a proposed measure of such National importance as is the one in question, should receive the attention and support of the Nation's lawmakers and of the people. The writer desires to be understood as speaking from the standpoint of the State concerning the necessity of National unity and a National head, as an advantage to the individual States in the present of state medicine in this country. The State Board of Health which he has the honor to represent is one of the early State sanitary organizations of the country, and the experience and observation of a quarter of a century have been at least of some value.

---

[1] Dr. Stephen Smith in the Sanitarian, December, 1883.

Among the functions of a National department of health may be the employment of scientists in the work of investigation in the present advanced work of sanitary science, and to inform State boards and co-operate with the same in practical sanitary work. It may respond to the calls of State boards for special services of experts in emergencies; it may direct in the establishment of new boards in new States and Territories; it would necessarily be the center for the collection and the Nation's school for the use of vital statistics; it would have as a department the whole system of National and interstate quarantine, and from its wide observation and experience, it would be able to advise Congress from time to time as to necessary legislation.

The general outlook may be regarded as satisfactory for the times. More then twenty years ago, when state medicine in this country was younger than it is now, Dr. Henry I. Bowditch, the eminent pioneer sanitarian in Massachusetts and first president of the State Board of Health of that State, spoke in prophetic words as follows: "We stand now at the very dawn of the grandest epoch yet seen in the history of medicine. While philosophically, accurately and with the most minute skill studying, by means of physiology, pathologic anatomy, chemistry, the microscope, and above all by careful observation, the natural history of disease and the effect of remedies, our art at the present time looks still higher, viz.: to the prevention as well as the cure of disease. And this is to be done by sanitary organizations throughout each State and the Nation. The laity and the profession heartily join hands in this noble cause." In this, the year of our Lord 1897, we find ourselves advanced quite near to the fulfilment of these anticipations. A few more State and Territorial organizations and a National department of public health at the head of all, would make the great sanitary working machine of the country quite complete. The modern vantage ground for work is found, among other things, in recent great discoveries in bacteriology, the means of immunization of the body to disease, the prevention of the passage of contagion, the cleansing of life surroundings by fire and water, the abolition so far as possible of disease cause, and the higher education of all the people in the means and conditions of physical life and purity. Well directed and well supported public service along these lines and with these means, belong to the present of state medicine in the United States.

THE PROGRESS OF THE INDIVIDUAL CUP MOVEMENT, ESPECIALLY AMONG CHURCHES.

Presented in the Section on State Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, June 1-4, 1897.

BY HOWARD S. ANDERS, A.M., M.D.
LECTURER AND CLINICAL INSTRUCTOR ON PHYSICAL DIAGNOSIS, MEDICO-CHIRURGICAL COLLEGE; PHYSICIAN TO THE SAMARITAN HOSPITAL.
PHILADELPHIA.

"Prove all things; hold fast that which is good," is apostolic advice too often and incorrectly applied to good things that are old; whereas, its obvious application is to things that are new. Not, indeed, should it be inferred that beneficent things ought to be despised, neglected, or indifferently treated because they are old, but, with a growing spirit of liberty and progressiveness of thought and effort so characteristically evident, that all things should be proved, good things should be held fast, while those which are bad should be cast away. Instinct and automatism avail nothing here.

The Pauline exhortation has fittingly been followed in the approach of our theme to its present point in several ways: principles, facts and figures constitute a substantial tripod for the support of a growing sanitary triumph wherever they may be accepted and utilized for their worth and adaptability.

The promiscuous and common use of a cup or other drinking-vessel has much about it that is traditional, conventional and customary; it is seen in public and in private; in institutions both sacred and secular; at ceremonies of a solemn or sentimental, jovial, lively or boisterous nature. But, is it consistent with the preservation and improvement of personal and public health under present day conditions? We believe not.

> "The best critics in the world are they
> Who, along with that which they gainsay,
> Suggest another and a better way."

Is there "another and a better way," along with which all that is essential in spirit and symbol may still be retained undisturbed, unmixed and untainted? We believe there is. It is realized practically, now, in the individual cup idea and movement; as a movement, however, it is yet in its infancy—but a few years old. Let us prove it; weigh it; consider it; hold fast to it and push it along if it is good, efficient and valuable, or reject it if it is bad, inadequate and useless.

The individual cup idea and the individual cup movement are the logical outcome of modern sanitary science. Clear and cogent reasons have led to the conception of the one; a consistent, courageous and practical spirit, to the birth and growth of the other. In the attainment of our present knowledge of the causes, modes of spread and means of prevention of the communicable diseases, in the development of the antiseptic and aseptic era in which we live, there has arisen simultaneously, intuitively almost, a more or less general and rational condemnation of the public use of a drinking-vessel in common under any circumstances. That this custom should be discouraged and prevented as speedily and universally as possible is an idea that must have originated independently in more minds than one.

The writer can testify to a distinct and forcible impression in this regard, about nine years ago, while participating in the communion service of a church of which he was then a member, and which was the first in Philadelphia to adopt individual communion cups (September, 1894). Doubtless many have experienced similar aversions to the common cup, in secular life more than in sacred ceremony, from perfectly natural thoughts of preserving one's self from that which is manifestly unclean, unsanitary, unnecessary, unmannerly and unchristian.

Then arose the question of the feasibility of the individual cup. Was it practicable? And finally, has actual use determined the individual cup to be practical and satisfactory, safe and successful?

It would be an essay of supererogation to elaborate the scientific argument in favor of the general use of individual cups before public-spirited hygienists and medical sanitarians. The logical circle of induction and deduction, of direct bacteriologic and analogous clinical evidence, and of well-established, almost axiomatic principles of hygiene, will probably be completed in your minds before this sentence is completed.

The purpose of this paper is to show from the history, progress and present status of the individual cup movement, particularly among churches, its timeliness, reasonableness, usefulness, efficiency and urgency; also, the need of personal and, perhaps, organized or official efforts by medical practitioners and sanitarians in furthering its beneficence still more widely than now obtains, gratifying though this is.

It is but a little more than three years since the sanitary agitation for individual communion cups or chalices began to demonstrate their feasibility in churches which were not opposed to their adoption for traditional, ecclesiastic, ritualistic or other reasons. In so short a time, the truth about so important an innovation has not reached all sections of the country; discussion—free, calm, unbiased and deliberate—elicits the truth, and helps to disseminate and establish it. Hence, while we have on several previous occasions attempted to awaken local interest and activity in this matter (Phila. Co. Med. Soc., September 1894; Baptist Ministers' Conference, January 1895; Med. Soc. State of Penn., May 1895), the occasion seems opportune and fitting to present it to this representative national body of medical men devoted to the interests of the public health; and we appreciate this privilege at the same time that we recognize the duties attached to it.

Our topic suggests at once a three-fold question: 1. Should common communion cups be abolished, from a hygienic standpoint? 2. If so, would individual cups be adequate and practicable substitutes therefor? 3. Again, if so, would their adoption conflict with any essential biblical teachings or practices in the Christian churches of today?

Let us review the main features of these points *seriatim*. Let the historic reveal and develop the rational. The first and second questions have a medical bearing strictly; the last question must be settled by bible historians, exegetes and critics, and the pastors of the various churches.

1. *The progress of the individual communion cup reform does show that the common cup is unhygienic and should be avoided and abolished.* In the first place, for years, the possible and occasionally probable transmission of disease by the common use of a drinking-cup has been recognized by physicians and by intelligent and thoughtful people generally. Its uncleanliness is a matter of common sense. So far as we know, Dr. Terry of Utica, N. Y., was the first physician to advocate, publicly,[1] a change in the ordinary mode of administering the communion wine. But no actual microscopic or bacteriologic investigation of the communion wine before and after service, with common cups in use, was made until early in 1894, by Dr. Chas. Forbes (U. S. M.-H. S.) of Rochester, N. Y. He presented a report, on March 7, to "a joint meeting of the session and trustees" of the Central Presbyterian Church of that city, in which attention was called to the uncleanly and unsanitary communion cup passed from lip to lip; and in which a small individual tumbler or cup, "about sixty of which could be placed on a tray of convenient size" was recommended. In a report to the Rochester Pathologic Society in April, he stated having found in the dregs of the ordinary cup, contamination from both the mouth and clothing; from the former, epithelial cells, mucus, and various bacteria and spores; from the latter, fibrous material. Control experiments showed the unused wine to be practically sterile.

In June of the same year, in seconding here in Philadelphia the conclusions and suggestions of Dr. Forbes, my own investigations, assisted by Dr. Furbush, were fortified by the discovery of tubercle bacilli in two out of five specimens from the dregs of a common communion cup, besides some pus staphylococci, pus, and oral epithelial cells. Such facts and their inference showed the probable dangers of disease transmission, and the vital and far-reaching importance of substituting individual cups, if feasible, since millions of communicants habitually participate in this sacred, symbolic memorial of our Lord's Supper.

The fountain-head of this sanitary but not sacrilegious agitation and reform, so far as conjoint, official and energetic endeavor on the part of medical men is concerned, certainly is Rochester, N. Y., with Philadelphia a close second. Even before Dr. Forbes' scientific report and design of an individual communion cup outfit, the Rochester Pathologic Society held a meeting (Dec. 7, 1893) at which, after general discussion on the question of the "Danger Attending the Prevalent Custom of Passing the Cup," introduced by request of Rev. Dr. Stebbins and Dr. W. S. Ely, a resolution was adopted unanimously recommending "that the communion ordinance of churches should be so modified as to lessen the liability to the transmission of contagious diseases which . . . attaches to the prevalent method of observance. . ."

After a paper read by the writer,[2] in which the historic, rational and practical argument in favor of individual communion cups was outlined, the Philadelphia County Medical Society also passed a resolution recommending "an individual cup method or system of administering communion in all churches. . . ; where the common communion cup is now in use;" and believing that the individual cups would afford a clean, safe and reliable means of preventing the spread of communicable diseases "from such a source as may reside in the ordinary chalice."

Evidence is not wanting then to prove, inductively, the dangers of a communion cup in common use. By analogy, the common drinking-cup having been clearly and justly proven a menace to the general health, as in schools, railway stations and cars, public fountains, etc., it is reasonable to believe that disease may be so transmitted in churches, though less frequently perhaps. Dr. Forbes referred to an epidemic of diphtheria which occurred among twenty-four persons in Rochester, and which was traced unmistakably to a common drinking-cup which all of the sick had used. All successful reforms of true and solid merit usually pass through three stages with the public: first, that of ridicule, indifference, or blind and prejudiced opposition; then, that of free discussion and the unveiling of the truth; lastly, that of ready, progressive and widespread acceptance and adoption, with beneficent consequences. The sanitary communion cup reform is no exception to this course.

---

[1] Oneida Co. Med. Soc., N. Y., January 1887.

[2] "Prophylaxis in Churches needed by the Adoption of Individual Communion Chalices or Cups." Trans. Phila. Co. Med. Soc., 1894.

Seemingly an unwarranted invasion of a sacred Christian ordinance, the movement was regarded at first by some of the clergy and a few of the laity with mingled expressions of horror, surprise, resentment and animosity. Condemned before it was considered fairly, the individual communion cup was treated contemptuously as based upon an imaginary menace to the health of Christian communicants and, therefore, merely a sensation or "fad." Calm, alert, frank and thoughtful ministers and church members, however, soon saw that the time was opportune for this sanitary and not revolutionary, reverential and not sensational, improvement in serving the sacramental wine. The lines became drawn for a while, and scattering shots occasionally, effective volleys not at all, were directed against the reform for a year or more,[3] with good results by increasing the interest all the more widely and deeply.

In reviewing the progress of events relating to this subject for the past three years, we may see that less emphasis has come to be placed upon the necessity of obtaining veritable evidence of actual disease transmission from an infected common communion cup or cups, in order that the demand for a change should be justified. Thus, right here we have the supreme value of established sanitary principles so applicable to the question at issue, that the importance of modifying the common mode of serving the communion wine is obviously a matter of logical deduction. Two fundamental principles supporting this movement are the security to health from cleanliness, and the preventability of contagious diseases, for they are preventable. Cleanliness is *not* next to godliness in the common communion chalice; it is far from it. If there is a real danger of disease being transmitted from mouth to mouth, at a common cup's rim, what diseases and of what gravity are they? Have any cases of disease thus arisen? Early objectors to individual communion cups were quick to put these and similar, as they thought, keen and critical questions to the advocates of a sanitary communion. We know of not one *bona fide* instance of disease contracted from a common communion cup. Let it be admitted candidly that it is manifestly difficult to prove as much; though this is not true of drinking-cups used for other purposes, simply because observation has been directed more closely to the latter as sources of infection. But, in the light of what evidence we have, and especially of the basic principles of preventive medicine, it is not at all necessary to show the report of any case to prove that our position is sound and tenable.

But who will say that many an innocent person may not have acquired disease from the common communion cup? Woeful consequences are statistically unknown and untraceable. It is probable that they have been produced, and even now may exist somewhere, knowing as we do that certain affections which may be present in those able to partake of the communion wine, are mediately communicable by the common cup. But we protest, is it reasonable, is it right, is it safe, is it Christian, to expose an hundred, a score, nay, even one, to the possibilities of disease, however mild, in the celebration of the Lord's Supper? It is not nearly so safe or sensible to have hundreds of persons whose condition of health and cleanly (or uncleanly) habits of mouth are unknown, drink out of a common chalice, as to have a goblet passed from mouth to mouth at our home tables; and that is not a common or consistent custom, even without favored guests to grace our hospitality. Nor is it likely, rather the reverse, that spiritual devotion or meditation will be encouraged by diverting thoughts and fears of physical contamination. We contend further that where no aversion to a common cup exists, apathy and that blissful (?) ignorance of hygiene because of which most of the world suffers, is to blame.

Among the maladies which may be carried from mouth to mouth by a common cup are syphilis, cancer, tuberculosis, diphtheria, scarlatina, influenza, tonsillitis, whooping cough, and others; the greatest of these is tuberculosis, the "Great White Plague," which, like the poor, we have always with us, principally because, not occurring in acute and alarming epidemic form, as do smallpox, diphtheria, cholera, etc., the fact of its contagiousness in insidious ways is not recognized generally by the public. Dentists urge strongly the importance of avoiding the common cup, because so many mouths are in an uncleanly, if not an unhealthy condition; neglected teeth, vitiated oral secretions, diseased gums, alveolar abscesses, pyorrhea, may be mentioned. "Sanitas," of London, writes: "In 1894–5, when influenza was very prevalent in England, the spread of it was noticed and put down to the same cause (common communion cup), in several of the church and other papers."

Some petty objections by sentimentalists against individual communion cups have been made, based upon the fallacious idea that vinous alcohol is a germicide. But this is not true, especially of the germs of some of the most prevalent, most contagious and gravest affections, even with pure, absolute alcohol; still less is it true with wine, where the percentage of alcohol is small. Furthermore, there are thousands of churches in which unfermented wine (grape juice) is used; and this is certainly consistent with another principle of hygiene—avoiding the temptation and disease and wretchedness of alcoholism—the "Great Red Plague,"—second only to tuberculosis in its destructive ravages. We know of a case where a reformed drunkard had his latent passion for intoxicants fired by partaking of alcoholic communion wine, and he ended in the gutter.

The medical testimony for individual cups which accumulated during the past two years is copious, convincing and pointed. Throughout the whole the "ounce of prevention" principle has grown to weigh pounds of potency. In Rochester, N. Y., where the first general agitation for a sanitary communion cup was instituted (December, 1893), in a definite, scientific and effectual manner, the advisors of a change embraced the majority of local physicians. Besides Drs. Ely and Forbes, already mentioned, were Prof. Dodge, biologist of Rochester University, Drs. Darrow, Barber, Mallery, and others. The writer desires to express his gratitude for public and private encouragement received from Philadelphia physicians "too numerous to mention." Dr. E. J. Howe, of Newark, N. J., has done earnest, effective and self-sacrificing work for the individual communion cup movement in that city and vicinity, aiding his personal efforts greatly by publishing a pamphlet for gratuitous distribution, in which numerous testimonials favoring this reform are given. Among the names are such sanitary authorities as Surgeon-General Sternberg, U. S. A., John B. Hamilton, Victor C. Vaughan and W. B. Atkinson; State Board of Health officers, as Drs. Probst of Ohio, Groff of Pennsylvania, Quine of Illinois, Caverly of Vermont, Baker of Michigan, Howell of Georgia, Cokenower of Iowa, and others, besides many local health officers, sanitarians and physicians. The progress of the sanitary argument for individual communion cups is well seen in the clear and forcible statements made. Drs. Hasbrouck of Brooklyn, Butler of Boston, Borland of Pittsburg, and Law of Oakland, Cal., also deserve credit for their able and enthusiastic advocacy of clean, untainted communion wine by means of individual cups. Medical journalistic commendation has also been pretty general. One editor writes as follows: "Notwithstanding the pooh-poohing of this movement by people who can see no danger in anything that is not sure death, it is steadily gaining ground." The London *Lancet*, of March 23, 1895, dwells upon the fearlessness of the modern reformer in warring against possible sources of infection, whereas before, criticism was little less than sacrilege. It then goes on to say that avoiding historic and religious aspects, we do not neglect the latter, nor are callous regarding pain given that there is even any idea of danger in the communion cup. "Moses, that prince of health officers, would probably not have sanctioned our present ritual." We may add reverently, that still less would Jesus Christ have sanctioned it. Progressive clergymen have argued against the common cup as being opposed to common courtesy, good manners, cleanliness, healthfulness, decency and convenience, as well as scriptural and early church history.

---

[3] "Present Status of the Sanitary Movement for the Adoption of the Individual Communion Cup." Penn. State Med. Soc., May, 1895.

Let us conclude this branch of our subject with a few characteristic quotations from physicians and pastors. "It is not pleasant to take the cup after it has been used by a sufferer from catarrh, decayed teeth, sore gums or tongue, or a tobacco chewer. The condition of many men's mustaches as they touch the wine is very repulsive to think of; . . . the wine is filthy and should not be used by others." "A practice which is not for a moment tolerated in civilized households, is doubly reprehensible under the conditions of this religious rite." "Esthetically it (the common communion cup) is nasty; from a sanitary standpoint, unsafe." "To drink after those we know is distasteful and unclean; to partake of the common cup at communion is unsanitary and disgusting." "The question seems to resolve itself into two propositions: one, the ethics of religion; the other, the ethics of hygiene." "Cleanliness is not sacrilege." "We are taking measures in our health board to prevent the sputa of the infected from poisoning the air, but we view calmly the passage of the cup from the diseased to others, and fear to call a halt lest we trespass upon the traditions of the dim past." "We do not need to confess squeamishness when we say that we do not have that spiritual relish for the communion cup which has passed five hundred lips before reaching our own." "It is not fastidiousness which causes people to abhor a drinking-vessel used promiscuously. . . . This fact of uncleanliness detracts greatly from the beauty, attractiveness, solemnity and effectiveness of the communion service." In its directions for the "communion of the sick" the Protestant Episcopal Church recognizes the danger of spreading known disease by the common cup. Would it not be equally wise, sensible and prudent to guard its rectors and parishioners against unknown but often lurking disease? Candor compels us to ask whether it is a true, intelligent, wholesome or refined sentiment that is willing to swallow the breath-blown, saliva-tainted, mustache-dipped and often tobacco-fouled wine of a cup that has passed the lips of fifty or one hundred or more good people? Does it not savor rather of sentimentalism and sickness, than of sincerity, security and spirituality? Dr. Butler, of Boston, in a very judicious opinion favorable to individual communion cups, writes that even if "illustrative examples were lacking as respects the risk involved in the use of the common cup, I should still advocate its abandonment, basing my action on the principle, when of two equally appropriate and practicable courses of action one is attended with a possible, even though a remote, danger of disease transmission, and the other is absolutely devoid of such danger, it is the part of wisdom to pursue the latter rather than the former."

2. *The progress of the individual communion cup movement shows that it is practical and permanent; and that individual cups are adequate sanitary substitutes for common cups.* At the outset the demonstration that common communion cups were uncleanly, unsanitary, illogical and inappropriate to the best, broadest and most benevolent spirit of the times, was presumptive evidence of the practicability of individual communion cups. A little ingenuity, industry, enterprise and adaptability would surely accomplish the desired results; and prove that the individual, in contradistinction to the common, customary method would be satisfactory and safe. Indeed, hardly had the need of reform taken definite and rational shape before individual communion cups were put into practical operation.

So far as our knowledge extends, the first church to use individual communion cups for sanitary reasons was the First Congregational Church of Saco, Maine, in November, 1893. It may be of interest to quote from a deacon's letter to us: "Having officiated at the communion service for many years and observing the mustaches, sore and tobacco-stained lips, the idea suggested itself to me that there must be some better way. Then, too, the hurried manner in which the cup was passed from one to another took from the solemnity of the occasion and I thought if each one could have a cup of his own more time would be given for meditation and prayer and it would be of greater benefit to each communicant; and, as at our tea-table we have individual cups, why not at our communion-table! The change has been very satisfactory." But the first extensive use of individual communion cups was made in Rochester, N.Y., where on the first Sunday in May, 1894, the Central Presbyterian Church used the outfit designed by Dr. Forbes, a member, for its 1,800 communicants; although on the Sunday previous the outfit was first put to practical test in the North Baptist Church, with its 240 communicants. It seems that the Baptists and Presbyterians had the courage, liberty, adaptability and foresight to unite on this question, if not on questions of doctrine and polity. Other churches of the same and various other denominations in Rochester soon followed in adopting individual communion cups, so that within one month fourteen had them in use and six signified their intention of adopting them. In July, 1894, a Congregational Church in Lima, Ohio, adopted the individual cups invented by Rev. J. G. Thomas of that city. In September, 1894, after our study of the common cup dregs, the Fourth Baptist Church of Philadelphia, of which the able, popular and scholarly Rev. J. B. Gough Pidge, D.D., is pastor, voted in favor of the change, largely through the enlightened activity of one of its members, W. E. Tolan, Esq., editor of *The Worker*, the church paper. A half-dozen other churches, Methodist, Presbyterian, Reformed and Congregational fell into line before long, and several other Philadelphia churches are now contemplating using individual cups.

In some localities the people are more conservative than in others, prejudice is difficult to overcome and ministerial indifference and the obstinate opposition of eccentric authority retards progress. Generally speaking, the laity of the churches are quicker to see the need of sanitary communion reform and the good features of the individual cups than are the pastors. It is a matter of education in most places, and who are more competent to teach the principles and energize the facts underlying the movement to the force of penetration than the physicians, who are really very near to the hearts of the people?

Statistic accuracy in the study of the individual communion cup movement is difficult, owing to the desire of many churches to avoid a publicity which might be sensational. But the figures obtained below show that during the little more than three years of progress considerable gain has been made. Indeed, the very quietness, but steadiness of the advance is good evidence of its stability and worth and that the movement is not a "fad." Our facts have been gleaned from personal knowledge, religious and secular newspapers, individual communion cup manufacturers and jewelry firms. Perhaps the number of churches now using individual cups is greater by half a score or more than we have learned of, as replies from some sources have not been received.

We may summarize as follows: *According to denominations:* Congregational churches 65; Baptist 42; Presbyterian 33; Methodist Episcopal 20; Lutheran 5; Reformed 4; Protestant Episcopal 2; Universalist 1; Disciples of Christ 1; Welsh Calvinistic 1; unknown denominations 50. Total 224. *According to States:* New York 33 churches; Massachusetts 39; Ohio 25; Pennsylvania 23; California 23; New Jersey 18; Connecticut 11; Wisconsin 9; New Hampshire 8; Maine 7; Illinois 5; Vermont 4; Michigan 4; Indiana 3; Iowa 3; Rhode Island, North Carolina, Maryland, Colorada, Texas, New Mexico, Oregon, Nova Scotia and Japan, each 1.

The number of communicants in the various churches range from 36 to 2,000. The approximate average number of communicants is about 450 to a church; about 100,000 altogether.

One needs but to see an individual communion outfit in practical use to believe in it. It is beautiful, simple, cleanly, sanitary, easily worked and handled by both pastor and people, adds harmony, dignity, impressiveness and devotion to the service. The individual cups are made of silver, plated ware, aluminum or glass. They vary from one and one-half to two inches in height, are made with heavy bases about three-fourths of an inch in diameter, toward which the sides taper in either straight or gently curved lines from the tops, which are from one to one and one-fourth inches in diameter, so that they are somewhat beaker-shaped; while others, again, may be shorter, with handles like small teacups, or even goblet-shaped. The cups (holding about one ounce) are served on hardwood or light polished metallic racks or trays, holding from forty-eight to sixty cups; the rack may have two or three tiers of twenty cups each set in shallow, round openings; covers to exclude dust may be raised and lowered over the cups. The cups are filled, partly only, from a tankard or fountain supported over the tray. It has twenty or thirty small spouts diverging from under its bottom, each spout corresponding to the position of a cup underneath. Or there may be a half-gallon bottle, with tubing, stopcock and metal pipe, from the under side of which are a number of small, short tubes corresponding to the number of cups in the row to be filled. According to the particular custom, after the communicant has been served—at the altar or in the pew—the cup is replaced on the tray or rack (tapering cups are easily telescoped in a small pile), or in pew rings, or in small racks holding five or six cups, to be collected after the service. The cups are cleansed first in warm, soapy water, with a sponge or swab, and then being placed in wire baskets, are immersed in boiling water for a few minutes. They are then dried, replaced in the chalice holders and put away in dust-proof cabinets until the next communion service.

Rev. V. M. Law, M.D., an Episcopal rector in California for the last ten years, prior to which he was a practicing physician and analytic chemist, has devised an ingenious, single sanitary cup with scalloped rim. It was designed to meet the requirements of a "one cup" ritual, but is not so simple in arrangement or strictly sanitary as the individual cup method. The scallops are used in succession by the communicants, each scallop receiving a sufficient quantity from a reservoir holding ten ounces, fixed within the chalice and so constructed that when the latter is tipped in the act of drinking, a bubble of air enters below so as to force out another supply of wine for the next communicant. During the past fifteen months Dr. Law has made a sturdy, single-handed and successful fight for a sanitary communion in his locality (Oakland, Cal.), and many churches are now using individual cups in consequence.

Wherever individual communion cups have been adopted, the testimony of pastor and people has been expressive of the utmost satisfaction. They would not be persuaded to return to the old method. There is a sense of relief in using a clean, sanitary cup, devotion is promoted, the ceremony reverenced. Ministers say that individual cups are more convenient, and that there is less time occupied in serving them, and without any confusion, than by using common cups. Again, from nearly all churches now using the individual cups come replies stating that the number of church-members who attend communion service has increased, and in some instances greatly so; in one Reformed church in New York the number of communicants was doubled; in a Presbyterian church "about 200 more communicants," and in another church 80 per cent. instead of 40 per cent. attend the service. One pastor writes that he has found "that the sanitary safety of the individual chalice appeals to the intelligence, removes all the objections of the sensitive and makes the service of the Lord's Supper more largely attended." . . . *The Congregationalist*, Dec. 26, 1895, speaking of nearly forty congregations which at that time had introduced individual cups, says: "Not an intimation of regret has been heard by us from churches now using the individual cup." Also, in a previous issue (April 18, 1895): "Nor is it a question concerning which the opinion of this or that man, who looks at it purely from a theoretic point of view, counts as much as the conviction of those who have had a chance to watch the practical operation of the system proposed."

3. *The progress of the individual communion cup movement shows that there are no valid objections to the use of individual chalices on scriptural, historic or present practice grounds.* This is a matter for the clerical profession to decide. Many more ministers, theologians, church historians, Biblical exegetes and critics ("higher or lower") than are associated with the churches now using individual communion cups, have pronounced a favorable opinion of the latter from their respective standpoints. Until fair consideration was given to the subject, the first feelings of most clergymen were those of resentment; but, as with exceedingly few exceptions they are intelligent and benevolent men, a little dispassionate and unprejudiced examination on their part usually results in reversing their positions of opposition to those of advocacy. There is a natural and, generally, wise conservatism which checks too hasty a change in religious customs. This conservatism is transformed into an equally wise and wholesome progressiveness, when the proposed change is seen not to encroach upon the spirit or essential doctrine of the custom.

The principal objection raised against individual cups has been that Christ used but one cup when He instituted the Supper. But the reply has been from many prominent ministers and theologians of all the various denominations that this can not be proved to be true; that He may have held in His hand one of many cups; that the Jews at that time used individual cups; that it is not stated definitely that His cup was passed around; that many churches in the past and at present use more than one cup, for convenience, in large congregations; and indeed, that the early Roman Catholic church used a tube or *fistula* for suction from the cup, and that a spoon was used by the early Greek church, and that objectors are inconsistent in stickling for "arithmetical and physical identity," since they ought also to conform to the first Supper in using unleavened barley bread, reclining at the table, etc. Certainly, if more than one cup is used, as is the practice in many Protestant churches, any number more than one may be used. It is no more unscriptural to use six hundred than to use six: on the contrary, it is more sanitary, logical, cleanly and commendable. And after all, there is danger of magnifying the letter and killing the spirit of the ordinance in bickering and hair-splitting about "the cup," since this is a minor detail as to significance, if any were intended; the *wine*, and not the cup, being elemental or symbolic.

"In essentials, unity; in non-essentials, liberty; in all things, charity."

Some have objected to the individual communion cup because they thought it destroyed the "feeling of fellowship," the unity of Christian brotherhood, and that it gave a "mistaken concession to the too prevalent tendency toward cleavage on personal or class lines." This seems like an imaginary and baseless sociologic sentiment. If it is discourteous to ask guests at our home tables to use a common cup, still more so is it to do so at the Lord's table, and surely, discourtesy is not conducive to good fellow feeling. "It should not be that social custom is in advance of religious custom." "It is hardly fair to read into this movement that which does not belong there. It is not an effort to emphasize social distinctions or to cater to the whims of the ultrafastidious, any more than good manners at the family table can be charged with breeding selfishness."[4] Common cups are not in accord with common sense, common courtesy or common sympathy.

In conclusion, what as to the future of this movement? Rev. V. M. Law of California, believes that "the strong tide setting in its favor shows that it must come or we will have depopulated communion tables." He thinks (himself an Episcopalian) that Episcopal clergymen need some pronunciamento on the subject from boards of health and medical societies, since it is not likely that they would heed personal professional appeals. But it is not probable that health boards will take any action, for fear of interfering with religious matters. Our own AMERICAN MEDICAL ASSOCIATION would certainly give great impetus to this sanitary reform by giving it official sanction and recommendation.

The trend toward individualizing drinking cups in general is so apparent and positive, though not yet so prominent and pervasive as we might wish, that it may not be too extravagant to express the belief that this particular hygienic reform may prove to be a "red letter" event in the history and development of sanitary science.

It is appropriate that the church, in its work of Christian beneficence, should be a leader in the application of sanitary principle wherever indicated, as in the administration of the communion wine. Not, let us hasten to say, because the evils of uncleanliness and possible contagion are greater than in other directions, as in schools, on railways, etc.—they are probably much less—but because of the unique and exemplary influence of the church. Furthermore, the province of the church of Christ includes largely an oversight of the physical, as well as the spiritual, intellectual and social welfare of humanity. "It stands for progress, and its example should always be on the side of the highest, most refined civilization." The individual cup and the "institutional church" have large futures for good before them—respectively, we may predict; conjointly, let us hope and strive for.

Compulsory Life Insurance.—From Berlin we learn that the government is preparing bills providing for compulsory life insurance throughout the whole empire, and for old-age insurance for the laboring classes. Delegates of the central insurance bureau have been asked to advise the government in this matter.

SURGERY ONE HUNDRED YEARS AGO.

AN HISTORICAL STUDY

BY DR. GEORGE FISCHER.

DEDICATED TO THE GERMAN SURGICAL ASSOCIATION.

TRANSLATED FOR THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION BY CARL H. VON KLEIN, A.M., M.D.

(*Continued from page 745.*)

XIV.—INFLAMMATION AND WOUNDS.

German theories on inflammation; J. Hunter's teachings on the finer precedency of curing inflammation and wounds; Treatment; Lumbar abscesses; Misuse of the sound and plugging of the wounds; Lint, poultice, cold water, lead preparations, etc.; Bloody suture; Fresh air, baths in fever; Cold showers in typhoid; Arresting hemorrhage, thrombosis; Ligature of the arteries; Compression, agaric; Early attempts at subcutaneous surgery.

If one conceives inflammation as the center of all pathology, because the ideas concerning the nature of morbid processes were strongly influenced by the prevailing conception of its development, he can only timidly enter into German science. No system sprang up which did not impress a certain stamp upon the theory of inflammation. In the beginning of the century the doctrine of Boerhaave prevailed almost everywhere in Europe. It consisted in a stoppage of the blood in the smallest arteries, which came about either because the blood had become thick and viscous through causes which removed the thinner parts (diarrhea, perspiration, etc.) or because different large drops of blood entered into the vessels in which they did not belong and obstructed them. The ideas of Boerhaave were modified variously. Hoffmann considered that the blood in stagnation had a tendency to putrefy; Stahl, that a congestion precedes the obstruction, etc. Haller was the first who without entirely denying the obstruction, believed that the blood exudes directly into the cellular tissue and that the seat of inflammation is there and not in the smallest arteries. All these theories, based upon false conceptions of the composition of the blood and of the blood vessels, were buried along with the systems. German surgeons also accepted them Heister placed inflammation in the same category with cancer and white swelling, and described them as heated swellings. Among external causes belong various injuries in which the blood vessels are lacerated, squeezed or so wrenched that the blood can not flow freely through them; as internal causes, all kinds of acridity which occasion a constriction of the blood vessels, and also too plentiful and too thick blood. In short, everything which constricts the blood vessels and makes them narrower, or so thickens the blood that it can not pass into the smallest capillaries was said to cause the obstruction and inflammation. The view of many surgeons, that the souring or fermentation ("Gierung") was the exclusive or in any way the principal cause of inflammation Heister considered as entirely erroneous. As the results of inflammation, he recognized the gradual dispersion of a disease, suppuration, mortification and scirrhus. A. F. Pallas and Brambilla considered the irritation of the nerves as the cause of the obstruction of the circulation in the finer arteries. E. Platner, together with Haller, placed the seat of inflammation in the cellular tissue. Richter opposed this opinion. He clung to the theory involving the smaller arteries and argued that the causes of inflammation lay "in the cramped tension, increased constriction and oscillation of the sensitive and irritable capillaries and blood vessels, in an increased flow of the fluid and a quicker movement of the same through the inflamed part."

Enough of these worthless theories of our countrymen. Our attention is drawn to *John Hunter*, whose work on inflammation and wounds was ridiculed by his contemporaries as a whimsical innovation, but has become the starting point of modern investigations and still forms the basis of present opinions. Hunter's great intellectual strength and the ample order of his ideas appear in these researches, if anywhere. They are rich in experiments upon animals, by which, in connection with microscopic investigations, Hunter sought to explain every striking natural phenomenon unfamiliar to him. He studied the heat of inflamed parts, the development of new vessels, the prima intentio, the formation of scars, etc., and in respect to those processes accomplished everything which could be done before the discovery of cells. Let us follow him! Since inflammation is not only a cause of disease, but is often also a method of cure, it is raised by this extended circle of effects to a main principle of surgery. Hunter divided inflammations, according to their outcome, into adhesive, suppurative and ulcerative. As a rule, adhesive inflammation precedes the suppurative; in very severe cases the suppurative inflammation can begin at once and pass over the adhesive stage. *Adhesive inflammation* arises first at one point, from which it spreads gradually; it is most severe at that point and weakens as it spreads. Next it appears to be an increased activity in the smallest vessels, based upon a distension of the arteries. It forces red blood into the vessels which otherwise contain only transparent fluids, so that the inflamed part through which now a greater quantity of blood flows appears to have more vessels. The extended vessels excrete upon the inflamed surfaces a coagulable lymph in which new vessels originate, whose increase and ramification the elder Hunter often saw quite clearly. In this way the dark red color and the swelling are explained, and into the neighboring cellular tissue the lymph exudes and thus causes the hardness of the swelling. It coheres and transforms itself into an almost organic part. In the adhesive period the new vessels serve to give the newly formed substance the power of activity and in suppuration tend to prevent the formation of a vascular granulation, while in the suppurative period they help to build such a formation. Inflammation affects the blood, and its components separate very readily. While the lymph coagulates more firmly, but more slowly, the red part has time to sink, by virtue of its weight, so that the lymph appears as a white membrane on the surface.

Suppuration never arises without previous inflammation, although it is not always in consequence of severe inflammation, since very slight inflammations are sometimes transformed into not very severe suppurations. The same vessels which previously excreted coagulable lymph into the cellular tissue gradually change their contents and excrete pus; therein consists the only difference between suppuration and adhesive inflammation. Yet the pus is not present in the blood, but arises first out of it without lacerating the vessels, as a product of a secretion analogous to the other excretions in the body. Richter considered these assertions of Hunter as too absolute, and believed with B. Bell that the pus, made chiefly out of the serum, but not completely formed and removed from the blood vessels into the abscess as [illegible] said. Hunter att[illegible] to [illegible]ree ca[illegible] ties which distinguish it from other animal fluids; it consists of globules, that float in a fluid which curdles a solution of sal ammoniac, and is the result of inflammation. Although Senac first mentions the pus globules, yet they were first investigated in Hunter's school. Home calls attention to the fact that by the red globules blood is distinguished from pus which contains whitish opaque balls in a watery transparent fluid, but that chyle has small spherules, and those in milk are just as large as in pus but more numerous. Everywhere people took great pains to distinguish pus from mucus; they found that the pus sinks to the bottom in spirits of vitriol and water, but that mucus floats; the former gives the water a cloudy, pale color, the latter generates in it floating filaments (Darwin), etc. Another discarded that distinction (Michaelis) and considered it of no practical value (Ford). When an absorption is combined with suppuration it is called by Hunter *ulceration.* The lymphatic vessels absorb either single constituents (chyle, fat and earthy substances of the bones) or actual parts of the body by which a wasting or a complete decay of the part follows. The latter is more apt to be the case with ulcers. In this absorption the principal effect occurs, probably from out the mouths of the absorbing vessels. Hunter denied that pus had the capacity to disintegrate the solid parts and transform them into pus. One effect of suppuration is *granulation.* This does not always presuppose a separation of the parts; only when internal surfaces are involved in suppuration must such be the case if they become granulated. Usually the contact of the outer air is a necessary condition, hence abscesses seldom granulate before they are opened. Granulation arises from the coagulable lymph which exudes and is transformed into a new substance; in it not only the old vessels extend themselves, but new ones arise. The granulations continue to excrete pus and have a tendency to unite with one another probably in the same manner as in the case of adhesive inflammation. When they approach each other the orifices of their absorbing vessels come in contact and coalesce. Like plants, which always grow from the center of the earth toward the surface, they strive to approach the skin. By another party the cell matter was regarded as the basis of granulation (Bichat: "Zellige Bläschen") and the formation of new substance was denied (Fabre, Louis). *Cicatrization* follows granulation. The hitherto separated parts are drawn together, especially at the edges, and it is a certain evidence of imminent healing when the skin in the region of the ulcer becomes smooth and white. At the surfaces of the granulations arises the epidermis, which one can regard as a new substance or as an altered surface of a granulation. Usually the new skin develops almost as an extension from the edge of the old, but not always. As in old ulcers, the new skin at first looks like small islands. While the new skin is not so flexible and elastic as the old, the parts around the ulcer thicken and harden in consequence of the exuded lymph. The German surgeons knew nothing of all these finer processes of the formation of granulations and cicatrization.

The effect of suppurative inflammation on the constitution Hunter designated as *symptomatic fever.* He said, "it is to be noticed that every local disease of any importance, or every disease which consists of a considerable and ready activity, even if it covers no great surface, affects the constitution more or less and produces appearances which, taken together, are generally called syptomatic fever. The symptoms of this are the expression of the sympathy of the constitution with a local disease or injury, and in consequence a number of conditions differ among themselves. They vary according to the nature of the constitution, which occasions very great differences. The modifications which age causes are included among these. They vary according to the tendency of the part in a diseased condition, and from this also arise great diversities: They vary according to the amount and kind of pain suffered, the way in which it was produced in the body; according as it is of a nature that immediately produces inflammation, as in cases of wounds, or less directly as when a part has become mortified; they vary in similar parts according to the situation of the diseased parts of the body; they vary according to the period of the disease." These views were shared by most surgeons till recently without receiving any actual accessions. The typical course of inflammatory processes and of the fever connected with them, was also announced by Hunter: "I will remark that every local or constitutional disease which possesses the power of bringing itself to a close usually shows a regular course and definite periods. . . . Since the regularity in the method of action of diseases leads to a final issue, it is something very desirable when the variations in the action of a disease show a repression of it either for a little time or permanently." Pyemic fevers had also become known. A. Paré had mentioned this fever which, dependent on the absorption of pus, is indicated by a shivering chill from twelve to fourteen days after the injury; he even saw the metastatic pus particles in the spleen, the lungs and other internal organs. F. Würtz likewise represented it as a "great vulnerary disease, vulnerary gall, and condition of unrest, which we now describe as pyemia." Hunter opposed the view, so very popular in the last century, that "hectic fever" is to be ascribed to pus absorbed from an abscess or ulcer, since he could not concede the admission of pus into the circulation as the cause of so great mischief as is usually attributed to it. Many surgeons deduced wound fever from absorption. Richter also admitted the absorption of pus, but said that healthy pus did little harm by its presence in the blood, while unhealthy pus, on the contrary, gave rise to very serious results. He distinguished inflammatory fever from wound fever, which follows injuries and operations and is not only inflammatory but also of a bilious nature. The German investigations in wound fevers have begun in our time at the point where Hunter left off.

The German surgeons held the same low point of view in the theory of *wounds* as in inflammation. The actual process of the healing of wounds was entirely unknown to them, and if they spoke of the rapid union and taught means to that end, yet no one knew in what it actually consisted. Into this darkness Hunter first brought light. He knew that there are a great number of injuries which need no treatment at all; for while diseases induce a defective action, injuries on the contrary always have a tendency toward restoration. He divided injuries into those which do not communicate with the outer world and the reverse. In the latter and in extravasations the escaping blood first coagulates and the coagulum becomes, as it were, the basis of restoration. Either vessels are formed in this, or they push out the originally contiguous surfaces of the severed parts and form extensions as in granulations. Hunter thought it possible to produce by injection the beginning of a new formation of vessels in the coagulum, where no vessels whatever could be drawn from the surrounding parts. Nerves also appear to generate in the coagulum. The second point in the healing of the extravasation is the closing of the lacerated vessels, whereupon, after a little time, the absorption of the superfluous discharged blood follows. It becomes a band between the severed parts so that the one does not unite directly with the other, but each with the blood on its own side. The healing *per primam intentionem* then consists in the organization of extravasated blood. By this the junction usually follows so closely after the injury that one could note it momentarily; when the blood has coagulated it adheres to the two severed surfaces, which it holds together; then the *prima intentio* has actually begun. The rapidity depends in part upon the amount of escaped blood. If it is great, then the blood does not become vascular in its entire extent, but only at the surface which is in contact with the surroundings, and the rest is absorbed. On the contrary, if the amount is small, as in slight wounds without laceration, and if all the parts are brought into absolute contact, the junction by *prima intentio* can be fixed after twenty-four hours. One sees this in head wounds and after the operation for harelip, although in the latter perhaps forty-eight hours are necessary to be sure of a perfect junction. Wounds often heal just as lesions which do not communicate with the outer air. Also simple wounds, as many resulting from operations, admit a *prima intentio*, but no bruises or wounds containing foreign bodies. This kind of cure was hardly known among the German barbers, but with the better surgeons soon came into extensive use. If one has such a method in view, it is in many cases not necessary to remove with great care the blood which covers both the wound surfaces for the purpose of bringing them into perfect contact, since the blood itself already establishes the connection. The orifices of the vessels soon close, the red part of the blood is absorbed, the coagulated lymph remains behind, becomes the actual means of holding the parts together, and later receives vessels and nerves. If *prima intentio* is impossible, inflammation ensues as a secondary action, and if this also fails granulations form. If the severed parts are left to themselves inflammation inevitably follows, which effects the exudation of lymph. This Hunter called "adhesive inflammation," and maintained that the adhesion comes about through the plastic lymph, which he considered necessary in every organic tissue. This inflammation requires about the same time for a junction as the *prima intentio*, which he distinguished from the former, while today they are regarded as essentially one and the same process. If the parts remain separated too long, suppuration is unavoidable. The old principle that a wound with loss of substance through granulation heals by "young flesh," came to be much doubted until, by experiments on animals, the old truth was again established. Hunter taught still another kind of healing, to which James Moore had already called attention in his prize essay on the healing of wounds (1789), that through *scab formation*. Nature effects this process without the aid of art, when the edges of the wound which are not in contact, so that *prima intentio* is impossible, become connected by means of a scab. The blood which flows from the separated parts coagulates in part and dries up of itself, or is absorbed by dry lint into a scab which covers the whole wound, and thus prevents suppuration. Formerly too little attention was given to this process, because the surgeons imagined themselves in possession of more powerful remedies than nature has, transformed every simple wound into a suppurating wound, and endeavored to prevent the formation of barks and crusts. Since the scab always needs a surface, it can form only on superficial wounds and on the surfaces of deep wounds, and therefore it must be prevented in gunshot wounds and wounds in which foreign bodies have penetrated. If such a cure does not take place the wound suppurates and no further harm is done. In many deep wounds the union beneath is more successful if a scab forms over the surface; hence many complicated fractures should be so treated, especially if the external wound is very small. How far one can carry these methods is not yet determined, but an everyday experience teaches that small wounds heal very well in this way, and in large ones there is no danger in making the attempt. If a slight suppuration follows, the scab can be opened a little so that the pus can flow out and all is well. If, in the meantime, the inflammation makes progress, the scab must be softened with poultices in order to loosen it. For burns by fire or boiling liquids this is the best method of treatment. While in English surgery the theory of scab formation was transmitted traditionally, Hunter's observations were so little regarded in Germany, where people were still submerged in their salves and plasters, that the literature of the first half of this century has almost nothing concerning them, and only after seventy years has the present generation taken them up actively (Volkmann, 1862)! We will leave Hunter's investigations, which are so similar to those of the present time that one could regard the one as the direct continuation of the other.

In the *treatment of inflammation* bloodletting, especially locally, stood foremost in Germany. Next to this, opium, which Richter considered the greatest antiphlogistic remedy, was given in England in large doses and preferably with calomel (Hamilton) or with ipecacuanha as a Dover's powder; then neutral salts, emetics and purgatives. Among the latter, castor oil was much less known to the German physicians than to the English; even in the year 1777 Theden knew nothing of it. In respect to external remedies Heister made a distinction between ardent and phlegmatic temperament, using poultices of vinegar for the former and for the latter brandy or spirits of camphor, always some heating agency. Richter determined accurate indications for irritant and emollient remedies according as to whether the inflammation was occasioned by weakness or irritation. He also made the assertion that by means of the application of the tourniquet to the extremities he could prevent or moderate a congestion of the fluids and the consequent inflammation ("Chir. Bibl.," i, c. 135). This idea, which as it appears he later abandoned, first gave rise to a practical result when Vanzetti in the year 1858 introduced indirect digital compression to the arteries for the treatment of inflammation. The *abscess* was opened in the middle by incision or, in case of patients who were afraid of the knife, by a corrosive (lunar caustic); if they opened spontaneously they were covered with a poultice. They were treated with lint covered with oil. In case of bubo, Sharp preferred caustic and taught that the abscess should neither be obstructed with plugs, syringed nor should be probed with the fingers nor probes; wounds should not be too scrupulously cleaned; the sore should never be wiped, but should only be dried with fine lint. He did not consider the influence of the air so injurious as was usually supposed, since large abscesses in the bodies of animals were observed to heal very well. As opposed to him, Richter insisted that the opening should never be made unnecessarily large, aside from the slanting sides of depressions; and then it were better to make counter-openings or to open the abscess by means of a seton recommended by B. Bell for preventing the admission of air. For enlarging he invented his curved scissors. The doctrine that all abscesses without distinction should be opened was already recognized as dangerous and it was recommended that those on the breast as well as suppurating bubo should be allowed to open spontaneously (Ford). Only on the most important parts of the body should they be opened early, and there is no surgical operation which demands a more accurate anatomic knowledge, since the abscess may arise anywhere on the body. For exactly this reason Richter had earnestly taught the young surgeons to be able to feel fluctuations, since nothing better revealed the skilled surgeon than the readiness with which he recognized deep-lying secretions of fluids, and a false diagnosis of this kind easily shook confidence in a surgeon. Up to this time the lancing of the little-understood renal abscesses had always proven fatal. Previous to 1780 David in Rouen make the observation that after their opening the pus which had at first been healthy soon became noxious, and he ascribed this change to the large incisions and the admission of air. He therefore pierced the abscess with a trocar and immediately applied a bandage. This method had only once proved successful and failed many times in his later experience. (Incidentally it should be noted that the trocar in its present form came into general use from France, after Petit had fashioned the feathered canula. Since then the name troisquart arose, *parce que sa pointe est triangulaire,* as La Faye says.) B. Bell also used the trocar for piercing, introduced a tube and employed a syringe; if the festering did not diminish after a few weeks he introduced a lead solution or lime-water. Abernethy first made the theory of the renal abscesses and their treatment generally known in surgery, through his work ("Surgical Essays," 1793), founded on several observations. According to him, if this abscess, which seldom has its seat in vertebral caries (frequently according to Ford), is opened and immediately closed, no inflammation ensues; the opening contracts and becomes perceptibly smaller. He did not believe that the admitted air was the cause of inflammation if all pus were carried away, any more than the absorption of pus caused fever. He recommended that the swelling be opened as soon as possible and he exchanged the trocar for the lancet, extracted in every case all of its pus and drew the opening together with adhesive plaster. He made a second puncture before the abscess had again reached its former extent, for the most part fourteen days after the first opening, and on one occasion cured a patient after five punctures.

In the *treatment of wounds* there prevailed, until the end of the eighteenth century, the dogma of the injurious effect of atmospheric air. According to Heister it was said to constrict and dessicate the small veins and to prevent the growth of the flesh; according to le Cat, it was said to cause suppuration in the obstructed blood vessels, the callous hardening of the wall of the wound, sores and the re-entrance of the pus into the blood. Heister recommended, therefore, that the air be excluded as much as possible by means of quick bandaging and that the wound should not be exposed before the bandage material lay ready and in shape. But instead of securing to the patient the advantages of fresh and pure air, he had the rooms fumigated several times each day with frankincense, mastich and the like. He knew nothing of ventilation. Pringle's views were adopted by Schaarschmidt, who also placed the wounded as far apart as possible and diligently attended to airing the wards. B. Bell also considered it of the highest importance in bandaging to avoid the evil and dreaded consequences of admitted air and therefore recommended, as did Richter, that every bandage be applied as quickly as possible and changed as seldom as cleanliness would permit. The frequent prize essays of the Académie de Chirurgie, already mentioned, show what value was attached to the treatment of wounds in the first half of the century. Richter adhered to the principle that nature alone accomplished the healing and the surgeon had nothing else to do but to remove accidental obstacles to the process and to moderate inflammation and suppuration. For simple knife wounds and cuts he recommended speedy conjunction. If among the great crowd of German surgeons there had ever insinuated itself a cardinal sin it was the *maltreatment of fresh wounds by probing them and filling them with lint.* How it is possible that for centuries the fundamental principles of surgery have been so ignored by the great mass and its eternal truths entirely forgotten it is difficult to conceive. Who will look down contemptuously upon literary studies, knowing that millions of human beings might have been spared so much pain and so much misery if the best teachings of our forefathers had been regarded. The abuse of sounding and the filling up of wounds can not be better described to German surgeons than by Felix Würtz in Basel in the year 1576! "With the explorer they probe, poke and stir in the wounds as if they had lost something there. . . . (Several physicians are present.) It is not enough that one should display his mercilessness with the probe, but after the first another also, and after him a third must seek for his lost penny and stir around in the wound, each one as rough and boisterous as the other. . . . But I do not know in the least how to characterize that practice, which is much in use, of filling all wounds, without distinction, with shreds, rags and other similar things and forcibly pressing them in. Medicines belong in the wounds and not such rags. . . . The pus is thereby obstructed and can not come out through the bolted door as it tends to do and as nature eagerly forces it." These abuses were not only thoroughly implanted among the Germans but in other nations also; they were handed down from one generation to another, although the best physicians of the time always protested against them. C. C. von Siebold wrote to Baldinger concerning the delicacy in probing and bandaging "without this quality in surgeons, surgery is beastliness." In the bandage-pouch which the German surgeon of Heister's time carried with him, were found in the case or "Sächlein" the following instruments: Small and large lances, straight and curved scissors, corn-tongues, razors, a straight, a curved and a two-edged knife, various probes ("Sucher"), a spatula, straight and curved needles. Besides these, a metal case contained several salves, plasters, vitriol, nitrate of silver, lint, ("carpey"), puff-ball and bandages. That in our day every evil has not been entirely eradicated is shown by the fact that only twenty years ago Stromeyer, in investigations of gunshot wounds, recommended the military physicians to throw away their probes; in the last Franco-Prussian war I myself heard, as an excuse for the squeezing out and filling of wounds, that they could not give the patients clean shirts every day. Ravaton spoke of the horrible manipulation of probes with which the breast and abdomen were torn up in cases of gunshot wounds, and he allowed them only for piercing a wound or to determine the presence of a foreign body. Bilguer also protested against much pressing and probing in gunshot wounds: "The indecisive and slow surgeons make an altogether superfluous and unnecessary use of the probe, which must be discontinued first of all; ten, even twenty. times they stick the probe into a wound, lay it away and use it just so again without reflecting that this probing is quite superfluous and injurious." Bilguer as well as Richter preferred to investigate with the finger in the region in which the part was injured because he could feel more nicely and irritated the wound less than with a probe, and he would rather widen the wound somewhat for the finger than to brobe it. J. Bell and J. Hunter likewise considered the finger the best sound for gunshot wounds. Bilguer had little need for a probe and thought it never should be used except in a few cases to determine the extent of the injury or to ascertain whether one touched a bone or a bullet. B. Bell insisted on the great importance of a free and unobstructed flow of pus and to that end recommended for deep wounds the adjustment of lead tubes instead of the easily obstructing pledget; this was drainage a hundred years ago! Silver tubes already applied to this purpose, which are resurrected in our own time by Hueter, he considered not so good because the lead ones were softer and more pliable. At that time the abuses were just as great in France, where in severe injuries blood-letting, recommended especially by Ravaton, and neglect of purgatives were practiced.

They applied pledgets with digestive salves to fresh wounds after the blood was stanched. Lint, and indeed dry, they used only at the beginning of suppuration; Hunter approved of it for the formation of scabs. At the end of the century, in France as well as in England, it was very much misused. Brambilla and the Frenchman Terras protested vigorously against it, and the latter recommended the curly lint above the long-fibered kind. In Desault's school it was applied very loosely; Wardenburg had learned that, and he said that whoever saves lint wastes the life of his patient. Pouteau recognized in it a frequent medium of contagion, when scraped by people who were impregnated with hospital air, and on that account he ordered that all the lint used in hospitals be prepared outside of them, and recommended, for the sake of economy, pledget paper instead of lint (It is well known that recently Roser endeavored to introduce blotting paper as a substitute for lint). Pelletan also attributed the rise of hospital gangrene to the fact that they had bound the wounds with lint which had for several years been stored in the Hôtel Dieu in the vicinity of the wards. For poultices they used all possible herbs, blossoms and roots boiled in water or milk. Indeed, it is interesting to know that our everyday cataplasm of linseed meal found its greatest advocate in J. Hunter; yet, every excellent gentleman who looks with contempt upon minor surgery, must remember that the greatest genius did not feel it beneath his dignity to give directions for the preparation of a poultice. Hunter thought the usual poultices too fluid and not thick enough to retain a proper form, and he considered the mixture of bread and milk too unstable. He recommended pouring on linseed meal a quantity of boiling water sufficient to make a paste of the right consistency, and adding some mild oil to a quantity of this mixture. He considered the poultice as the best means of bandaging in gunshot wounds and in most lacerated wounds. Later, that deep thinker, Abernethy, took the pains to instruct his countrymen in the preparation of poultices, and for thanks was derided as the "poultice crank." In France, where in the last decade of the century wounds were often so assiduously washed out that not a drop of pus remained, poultices were more in use than any other remedy. At the entrance of the hospital the attention was arrested by great tables with pans full of linseed meal and marshmallow water. Their frequent use was based upon the idea, very general in France, of a so-called "depot." If a little redness and swelling was formed, they did not inquire whether pus was already present, but whether it were yet formed, and they endeavored to soften the swelling.

Cold water must needs be discovered anew. In the seventeenth century it seemed too simple a remedy, they applied only salves and plasters to wounds. Although in the first half of the eighteenth century the Englishman Smith and the Frenchmen Lamorier and Chirac brought forward cold water again, still the methods seem to have been forgotten. Our Schmucker has the great honor of bringing it again into use in injuries and inflammations. In accordance with the physiologic views of the time he wished to have, for his patients with head injuries, a remedy "which would contract and strengthen the relaxed vessels, especially the tender lymphatic and serous ones, besides preventing a further exudation of lymph and hastening the absorption of that already discharged." He took cold water, since he could get no ice, which he would have decidedly preferred, and to increase its effectiveness made a mixture of forty pounds of water, four pounds of vinegar, sixteen ounces of saltpeter and eight ounces of sal ammoniac; he called this his fomentatio frigida. Theden followed him, and the Frenchmen Lombard and Percy. Richter had little to say of cold applications, nothing at all of ice; but Hunter, who valued it highly for inflammations, thought it was not so generally applicable as other remedies.

The *lead preparations*, introduced in 1760 by Goulard of Montpellier, made considerable sensation, especially acetate of lead. Without any indication the barbers and bathers applied lead preparations to most surgical diseases, insomuch that all other remedies were forced into the background. This enthusiasm lasted some twenty years, till Aitken in England, and then Hecker with us, assigned narrower limits to these remedies and taught a more guarded application of them. Desault, and B. Bell, who injected a weak solution of lead into wounds but as for the rest protested against powerful injections, and also Theden, were very partial to these remedies. In the second half of the century, in all countries, a reaction against the excessive use of salves and plasters began to prevail. Würtz had said in this connection, "that they cleansed wounds with rags saturated with oil and salve in the same way that a guard cleans out the barrel after he has shot off a gun, and the practice of treating all wounds with the same salves and plasters is just as senseless as it would be to fit all feet with the same shoes." The German surgeons in Heister's time bound small wounds with brandy or honey, oil of turpentine, Johannis oil; Peruvian or some other wound balsam; they preferred balsam and spirituous poultices for incisions because they dried the wound more quickly; oil and digestive salve for bruises because they hastened suppuration. When one reflects upon the simple, almost dry treatment of wounds of antiquity, he is disgusted with the enormous amount of salve-smearing of this time, which began with the decadence of medicine. Instead of the usual *bandages* of linen, B. Bell preferred flannel because it is elastic, fits firmly and yields to the swelling of the part. His countryman, Gooch, recommended laying a fresh *wax sheath* on the compress to protect the bandages from pus.

The *bloody suture* in wounds was almost entirely discarded during the eighteenth century. That was the same stand which F. Würtz took, who condemned the suture on account of the scar it leaves, of the tearing up of the filaments in a growing tumor and of the seizure by the suture of nerves in general. They preferred a ligature with adhesive plaster (or English plaster) in most cases. J. L. Petit and Hunter gave adhesive plaster the preference over bandages; the former because the bandage covers the whole wound, obstructs excretion and is adjusted sometimes too loose, sometimes too tight; the latter because the adhesive plaster induces neither inflammation, suppuration nor ulceration, which the bloody suture always does. Adhesive or English court-plaster is therefore best adapted to amputations, operations for harelip and the extirpation of tumors. Sharp, on the contrary, sutured all fresh incisions and found that sutures on the head were less injurious if they were carefully made. In Germany Heister preferred the so-called dry union and only when necessary, especially in large oblique and angular wounds, would they resort to the bloody suture, because it caused pain and new scars. Richter restricted the use of sutures as far as possible on account of irritation and inflammation, and gave the dry method preference without actually discarding the other. He made the suture with a curved needle and a thread which was composed of separate single strands, was waxed and resembled a small bandage. He had the stitches lie, for the most part, a thumb's breadth apart and two or three lines from the edge, and pass through the base of the wound; the threads were fastened with a simple knot and a noose.

Concerning the *treatment of fevers* we will select only one point which has special interest for our time. While from Hippocrates down heat was considered the pathognomonic symptom of fever, in the eighteenth century they laid the greatest stress upon the acceleration of the *pulse*. According to Hunter the regularity, irregularity and rapidity of the pulsations depend only on the heart, while the strength, the undulation, the fulness and weakness, the beating in two throbs pertains only to the arteries. He believed that the condition of the pulse is not easy to determine and that one can only learn to judge its weakness, strength and tremor with accuracy by experience. Many physicians never learn this, as for axample, William Hunter who could not feel the fine differences of the pulse. These can be perceived only through the soul, and it is just as in music, when much sounds inharmonious and unpleasant to the more sensitive ear which is not so to another. In England the use of a pulse-watch was highly esteemed as the only sure method of judging of the pulse, since even the most experienced practitioner deceives himself without such an instrument (Fordyce). Ignorant braggarts, on the contrary, sneered at the use of a second-watch, as Brambilla, for example. In this connection it must be remembered that in Germany, even in the middle of the century, the possession of a watch was frequently dispensed with. It is known, that Semler only obtained his silver watch when he was a professor, while about the year 1780 every master and student required one. Influenced by Pringle's ideas the English physicians laid great stress on *pure and cool air* in the treatment of fevers. Everywhere the ordinary man desired for the fever patient a narrow, hot, sometimes ill-smelling chamber. The patient lay buried in bed and was given special drinks to promote perspiration as much as possible; change of bed linen and shirt was strictly forbidden. Gregory in Edinburgh (1772), opposed these abuses sharply, let cool fresh air into the sick room, constrained the fever patient not to eat and drink, but allowed him as a drink all the cold water or thin beer that he would take. He also let the patient stretch his hands and feet out of bed at pleasure, and had the bed linen changed daily. Fordyce in London (1773), knew that the human body can be more quickly cooled by air cooler than itself than by internal medicines. He desired cool moist air, large rooms with fireplaces, roomy beds and a frequent change of bed linen and shirts. It surprised him very much that his German colleagues had their patients lie in rooms where the air was so extraordinarily hot and bad. And yet de Haën had already taught (1757) that excessive heat aggravates diseases and therefore a moderate temperature is necessary; he had his fever patients lie on the outside of the bed for a few hours, which refreshed them greatly and induced a gentle sleep afterward. By the misdirected care of stupid nurses, who avoided every draught, the disease was newly aggravated, indeed sometimes fatally. Hunter also valued fresh air as of the utmost importance in guarding against the so-called hospital fever, which arises chiefly through the abode of many persons in narrow rooms (as in prisons, ships and small dwellings of the poor), by which the air becomes infected (1785). Before all things he desired to create pure fresh air by ventilation in hospitals and dwellings, and on the other hand to banish all fumigations, since they only conceal the bad odor but do not improve the air. It was known that general *bathing* was of great use in fevers. Le Cat had patients who had been operated on for stone placed in a half bath after the operation. Boucher extolled baths for gunshot wounds; le Dran, after all surgical operations. Even in the field-hospitals Bilguer made baths possible, and in Nimes, where he had forty-one patients with putrid fever and dysentery under treatment, he had each one given a daily tub-bath with infusions of chamomile and other things. Incidentally let us notice internal medicine. In England they began to make use of cold water as an antipyretic remedy, especially *cold baths in typhoid.* The merit of having energetically developed this method belongs decidedly to the Prussian physicians, Siegmund Hahn, father and son, who used cold water extensively for both internal and external ailments. (J. S. Hahn Sohn, "Unterricht von Krafft und Würkung des Frischen Wassers in die Leiber der Menschen," u. s. w., 1738.) Currie first used baths in typhoid methodically. Wright showered his typhoid patients with cold water, the earlier the better (1799), while Gregory had his bathed in it twice a day, after which he observed a reduction of the fever and a decrease in the pulse from 110 to 80 beats. Baths were recommended by Scott, who had his typhoid patients afterward rubbed with rough flannel, put in bed and given warm wine; likewise Dimsdale, who inserted a thermometer under the tongue of the patient to ascertain the degrees of fever. Even during the first days after the baths, which he considered more effective than bathing with a sponge, he observed an abatement of the fever and headache, and discontinued them only in case of great exhaustion. (In intermittent fever the Englishman Kellie observed the chill to be relieved in a few minutes when a tourniquet was applied to the right arm and the left thigh; he found that the tourniquet, applied to himself in a healthy condition, at first increased the number of pulse-beats and then continually decreased it (1794).

We will pass to the *arrest of hemorrhages.* The question as to how nature can stop the flow of blood was first answered by J. L. Petit (1731), by the evidence of a thrombus, and he thereby gave occasion for much investigation and contention. His thrombus consisted of an external coagulum adhering to the orifice of the artery (*couvercle*) and an internal coagulum arising at the end of the blood vessel itself (*bouchon*). Morand agreed with this view in part and first demonstrated that the inner and middle coats of the arteries constrict themselves, and thus retain the thrombus. He attached the greatest importance to the fact that the severed vessels recoil and shorten, and thus the force of the blood flow is diminished and finally the opening of the artery contracts and at last closes. Other surgeons, as Aikin and Gooch, who thought the formation of a coagulum at the natural heat of the body impossible, regarded the obstruction which they found in the arteries upon dissection, as a product of death. Again, others maintained that the arrest of blood by an obstruction is untrue, because after a little time one finds the end of a severed artery entirely closed up to a certain length and changed into a ligament (B. Bell and Theden). A chief role was allowed to be played by the coagulation of the blood extravasated into the cellular tissue, which exerts a pressure upon the arteries and by the inflammation induced by the ligature, which results in the withering of the constricted part and the adhesive cicatrization of the end of the artery (J. Bell). White even considered the obstruction as an impediment to the closing of the artery, because it held the passage open, and he advised removing it with a sponge. Kirkland also regarded the coagulation of the blood as injurious and rejected Petit's views, because in many cases a swoon will very quickly staunch a hemorrhage of even the large arteries. Pouteau occupied a middle ground, in that he admitted the formation of an obstruction, but considered as the best means of closing the artery the swelling of its end and of the cellular tissue surrounding it, by which it is compressed; for he sometimes found the obstruction, sometimes not, and in the latter case observed that the end of the artery was closed by a solid callous scab; he therefore denied the necessity of the formation of a thrombus and declared against the retrocession of the blood vessels, because he often saw them extend beyond the surface of the wound. Richter also adhered to the double process, but at the same time to the retrocession; he maintained that opened arteries were closed either by a blood obstruction or by complete cicatrization, which usually extends to the next branch of the artery, in the latter way always in transverse incisions and *vice versa.* The demonstration of this double kind of arrest of hemorrhage he found in the fact that when the opening of the artery was closed by some external means, the blood behind stagnated and coagulated; but if close above the compressed or constricted point, a branch opened, the blood flowed there and consequently could not stagnate and form an obstruction. He doubted if this alone, in the first days after an injury, would contribute to the arrest of the hemorrhage of a large artery, because its force would soon expel the obstruction. Yet he did not doubt the existence of the thrombus, in general, and he added, as further evidence, the observation that in gunshot wounds one sometimes sees clots of blood float in the pus, which one must handle very carefully, because at its removal an excessive hemorrhage often arises. The dispute in regard to thrombosis entered upon a new stage when it was demonstrated that the thrombus organizes itself, and Jones published an excellent work in the year 1805, with the results of some fifty experiments on horses and dogs.

Surgeons were not united as to the various means of arresting hemorrhage, although the ablest of their time preferred the ligature, if in any way applicable, to compression or styptics. In flaming letters history teaches us how, in an inconceivable manner, one of the noblest treasures of surgery, *the ligature of blood vessels*, could lie buried for centuries; how, again brought to light, it was again forgotten for centuries; how, discovered for the third time, but bitterly contested, it was not forgotten from this time forward, but only after a long time was it accepted as one of the most precious gems belonging to surgery. The first period lay in antiquity; Hippocrates, Galen and Paul of Ægina used the ligature. The operation for aneurysm by the ancients, shows that they also bound up the main vessels with the needles. The Greek, Archigenes, is considered the discoverer of the ligature in amputation (97 A. D.); he said that the surgeon before amputating should bind up (*i. e.*, with strings) the blood vessels leading to the limb, and should then make them fast (*i.e.*, ligate them with the needle). If the ancients almost never employed the ligature in amputations it was not from ignorance of its manipulations, but because of the rarity of those operations at that time. They amputated only in cases of gangrene, and made it a principle in clean fresh wounds to bind up the blood vessels, but in putrescent wounds they arrested the flow of blood by cauterization. The ligature was forgotten and only in the twelfth century discovered by the Arabians, Albucasis and Avenzoar, and again used. By the former it was called "ligetur cum filo ligatione forti," by the latter, "ut primum liges extringendo caput ipsius venae quae est versus cor et postea incides," (Ullersberger).[1] And the Arabians were no further thought of.

For centuries the hot iron triumphed in general practice until, for the third time, Ambroise Paré, the surgeon of King Henry II., Francis II., Charles IX. and Henry III., in the sixteenth century, again brought the ligature to light. His great service consisted in defending ligature as the only safe method, in opposition to the barbarous method of his time, for stopping hemorrhage, the cruel burning of the amputated stump with a hot iron, amputating with redhot knives and inserting the stump into seething pitch and oil. As thanks for his operation, which, for a long time, was looked upon as a new discovery, it was decried and disparaged by the adherents of the hot iron. A contemporary, the envious Gourmellin, thus wrote of him: "An ignorant and at the same time rash man has lately, out of ignorance and pride. ventured to condemn the cauterization of the blood vessels with a hot iron after the amputation of limbs, a method which has been recommended by all the ancients without exception and has always been approved, and in its place has to introduce a new expedient, namely, the ligature of the blood vessels, something contrary to all the teachings of the ancient physicians, to all first principles, to all experience and to all sound reasoning. . . . Truly everyone who undergoes this butcher-like operation has reason to praise God if he comes out alive after this cruel and inquisitorial torture." Paré followed two principal methods. Most frequently he had his assistant draw out the arteries with his pincers (*bec de corbin*) and tie a thread around them, or he secured them with needle and thread if he could not readily isolate them. Some flesh was always bound in with the artery. It was no light task for Paré to abolish the hot iron, whereupon for justification of the ligature he based his claim upon Hippocrates, Galen and Avicenna. At the same time F. Würtz felt that the hot iron must be abandoned, when he said: "It is, in my opinion, such a horrible expedient that it should again be given over to murderers only. For I can readily believe that such an expedient was learned by hangmen's children." He had seen much pain and misery from the hot iron and permitted it for the most part only in thigh amputations, and in other cases he arrested the bleeding with alum. It must be admitted that Paré exacted a great deal of faith from his contemporaries, for he possessed but crude experience and was not in a position to demonstrate the effect of the ligature upon the blood vessels nor to establish its superiority over other methods; his technique itself was imperfect. Therefore, for a long time, general confidence was withheld and and the most celebrated surgeons of that time, such as Severin and Nuck, considered the ligature as very dangerous. Indeed, more than a hundred years must pass before it won the sovereignty over all other methods in surgery. The Germans learned to know its value earlier than did Paré's countrymen. Scultet and Fabricius of Hilden used it, the latter, however, only upon young and strong men. In France, Guillemeau, the pupil and friend of Paré, and Dionis were the only ones who, up to the end of the seventeenth century, knew how to appreciate it, and they did so only in a limited way, that is, they preferred it to the hot iron in amputating injured limbs. Wiseman performed the same service for English surgery. Nevertheless, during the first half of the eighteenth century in France, cauterization still prevailed and, in the Hôtel Dieu in Paris, was used exclusively in hemorrhages attending amputations.

(*To be continued.*)

Synopsis of the Report of the Surgeon-General.

War Department, Surgeon-General's Office,
Washington, D. C., Sept. 22, 1897.

Sir:—I have the honor to submit the following report of my administration of the duties pertaining to the office of the Surgeon-General of the Army.

Among the expenditures authorized by Congress for the fiscal year ended June 30, were those for artificial limbs, for surgical appliances and for trusses for persons disabled in the line of duty, for the Army Medical Museum, for the library of the Surgeon-General's Office, for the support and treatment of destitute patients in the city of Washington, D. C., for the construction and repair of army hospitals and for the support of the Medical Department of the Army.

Artificial limbs.—During the year ended June 30, 1897, there were furnished under the laws relating to artificial limbs 301 artificial legs, 7 arms, 4 feet and 1 apparatus; and the commuted value of an artificial leg was paid in 2,856 cases of amputated leg, of an artificial arm in 2,993 cases of amputated arm, and of an artificial foot in 69 cases of amputated foot. Commutation was paid also in 3,297 cases in which the use of a limb was lost. The money expended amounted to $555,347.51, of which $552,854.46 was from the current appropriation, $2,452.35 from the appropriation for 1896, and $40.70 from that for 1895.

Appliances.—The number of appliances issued during the year was 176, for which was disbursed the sum of $1,015.27 from the appropriation approved June 11, 1896, and 136.50 from that approved March 2, 1895, a total of $1,181.77.

Trusses.—There was expended in furnishing and fitting trusses to disabled soldiers under Sections 1176-78, Revised Statutes of the United States, and the Act of March 3, 1879, the sum of $7,268.80. The number of trusses issued and fitted during the year was 1,043.

The hospital corps.—The loss to the Corps during the year amounted to 273 men, but this was more than offset by a gain of 276 men by enlistment, re-enlistment, transfer, etc. The Act of March 16, 1896, reduced the number of hospital stewards, and fixed it thereafter at 100. There remained in service June 30, 1897, 98 hospital stewards, 99 acting hospital stewards and 513 privates, a total of 710 men.

The Hospital Company of Instruction at Washington Barracks and the smaller detachments in the Western departments contribute materially to the training of the men in their important duties, and serve also as depots from which vacancies in the respective departments are filled. The instruction given them includes nursing, cooking, first aid to the sick, litter and ambulance drill, pharmacy, assisting in operations and disinfection, taught both theoretically and practically, with field work as far as possible. The company at Washington Barracks received 46 men during the year, and from it 42 trained men were sent to other posts.

The appropriation for the support of the Corps for the fiscal year 1896 7 was $206,280. As this was more than sufficient, the appropriation for 1897-8 was reduced to $202,800.

Medical and hospital supplies.—The disbursements during the year ending June 30, 1897, from the appropriations made by Act of Congress approved March 16, 1896, for the expenses of the Medical Department of the Army, and from the balances of previous appropriations on hand at the beginning of the said fiscal year, amounted to $108,709.38.

Recently issued medical works and improved appliances of various kinds have been supplied to the hospitals during the year. A few of the principal posts have been provided with the Roentgen ray apparatus.

Therapeutic value of medicinal tablets.—During the year an investigation was made into the efficiency of the medicinal tablets issued from the medical supply depots. The results showed that the tablets do not suffer any more from deteriorating influences than other preparations of the same medicines. They are valuable in presenting to the medical officer accurately divided doses while occupying little space in the medical chests; but they are not in every instance to be regarded as pharmaceutic preparations ready for administration. Tablets of bromids, iodids, etc., would be highly irritant to the gastric mucous membrane if swallowed without previous solution and dilution, and those containing more or less insoluble substances such as phenacetin, salol, sulphonal, etc., would be slow to act or even inert unless thoroughly disintegrated before administration. The necessity for suitable preparation for use in each case should always be held in mind.

---

[1] When Ullersberger made the reproach against our time (*Deutsche Zeitsch. f. Chir.*, II, S. 260, 1873) that it falsely ascribes priority in ligature to Paré, while it is exclusively the fully authorized property of those two Spanish Moors, by whom he maintains this precious jewel was discovered, he overlooked the fact that, in the previous century, the position of Albucasis as regards ligature was cited by E Platner ("Zusätze," I, 1776, S. 255) and this Arab is also mentioned by Sharp. Further, the accounts of Hippocrates and Archigenes were as well known to E. Platner as to Cocchius ("Graec. chir. libr.," 1754, p. 157), therefore the former does not ascribe the discovery of the ligature to the Frenchman Paré, but the great merit of reintroducing it. These things are not forgotten to the present time.

Hospitals at military posts.—Great improvement has been made during the past few years in the hospital accommodations at many of our military posts. At the present time new hospitals are in process of construction at six posts: Forts Hamilton and Wadsworth, N. Y., Fort Hancock, N. J., Fort Monroe, Va., Fort Custer, Mont., and Fort Spokane, Wash. In 1896 a hospital was completed at Fort Logan H. Roots, Ark. In 1895 new hospitals were erected at Fort Myer, Va., Fort McHenry, Md., Plattsburg Barracks, N. Y., Fort Meade, S. Dak., and Fort Harrison, Mont., and in 1894 at Washington Barracks, D.C.

These hospitals are of brick, with a two inch air space in the exterior and no furring on the inside, the plaster being applied direct to the brick work and finished with soapstone. Pressed steel ceilings are used on each floor above the basement. Each building is heated by hot water and ventilated through galvanized iron ducts and brick flues by direct-indirect radiation. The basement is concreted, well ventilated, and usually contains a boiler room, coal room, several store rooms, a vegetable cellar and a large room under the ward wing which is used as a drill room for the detachment of the hospital corps in bad weather.

Providence Hospital.—The Act of Congress approved June 11, 1896, appropriated $19,000 for the support and medical treatment of destitute patients in the city of Washington, D. C., under a contract to be made with the Providence Hospital by the Surgeon-General of the Army. The amount of relief afforded under this appropriation was equivalent to the treatment of 113 patients throughout the year.

Army and Navy General Hospital, Hot Springs, Ark.—Twenty-five officers and 106 enlisted men were treated in this hospital during the calendar year 1896. Of the former 19, and of the latter 56 were returned to duty or left the hospital very much improved. Reports received from the surgeons of the various posts six months after the 56 men had been returned to duty, showed that 39 were doing full duty with their companies, 5 had been discharged on expiration of term of service but were in good health at the time of their discharge, 2 had deserted and 10 had been discharged on account of a recurrence of their disease.

Almost every case sent to this hospital is a case for discharge on certificate of disability at a post. All the benefits to be derived from the treatment there have been unavailing, and but for the special facilities afforded for treating such cases at the Hot Springs many men who are now returned to duty would become pensioners of the Government for years.

On my recommendation, in May last, the President directed the amendment of the regulations governing admission to this hospital so as to admit to its benefits honorably discharged soldiers and sailors of the regular and volunteer Army and Navy of the United States when there are vacant beds in the hospital for their occupancy. Circular No. 1, May 8, 1897, from this office, published full information for the guidance of applicants for admission. Since then 13 individuals belonging to the classes mentioned have taken advantage of the privilege. When the authority for their admission for treatment becomes generally known there is no doubt that many veterans of the war disabled by rheumatism and other diseases which the waters of the Hot Springs have an established reputation in benefiting will become applicants for admission.

Army Medical Museum.—The amount expended during the year on behalf of the Army Medical Museum was $4,882.76. The number of specimens added to the Museum during the year was 3,156, making the number on hand June 30, 1897. 36,897.

Library of the Surgeon-General's office.—The amount expended during the year on behalf of the Library was $10,000. There are now in the Library 123,924 volumes and 210,152 medical theses and pamphlets, the additions during the year having consisted of 3,580 bound volumes and 11,612 pamphlets. Volume ii, second series, of the Index-Catalogue, includes the letter "B" and forms a volume of 954 pages. It will be ready for distribution at the regular time. The appropriation for Volume iii, second series, having been made, the manuscript is in course of preparation for the printer.

Medical officers.—There were 108 medical officers reported to this office as having been on duty with scouting parties and on other field service during the year.

Deaths. Two surgeons with the rank of major.

Retirements. On request, after thirty years' service, one assistant surgeon-general with the rank of colonel; one surgeon with the rank of major. For disability, two assistant surgeons with the rank of captain. By operation of law, one assistant surgeon-general with the rank of colonel; one surgeon with the rank of major.

Promotions. Two deputy surgeons general with the rank of lieutenant-colonel to be assistant surgeons general with the rank of colonel; two surgeons with the rank of major to be deputy surgeons-general with the rank of lieutenant-colonel; six assistant surgeons with the rank of captain to be surgeons with the rank of major; eleven assistant surgeons with the rank of first lieutenant to be assistant surgeons with the rank of captain.

Appointments. Eight assistant surgeons with the rank of first lieutenant. These were selected by a board convened in Washington, D. C., Sept. 23, 1896. Forty-seven candidates were invited to appear before the board; six failed to appear; twelve were rejected for physical disability; fourteen were found disqualified professionally; three were rejected at preliminary examination; four withdrew after partial examination. Eight were found qualified and were recommended for appointment.

Vacancies. There are now, June 30, 1897, five vacancies in the Medical Department.

The Army Medical School.—The report of the President of the Army Medical School on the work of the past year shows the earnest endeavors of the members of the Faculty to make the course of study one of the best of its kind with the facilities at command. The practical instruction in operative surgery is a valuable preparation for the responsibilities of service in the Army, where the surgeon has frequently to act for himself in cases which in civil life would be treated only after professional consultation. The laboratory work in bacteriology and sanitary chemistry is also of great importance. The teachers of these branches have reported as the result of their experience during the past three sessions that a course of four months does not give them time to deal with their subjects in a thorough and satisfactory manner. To enable them to do this G. O. 43, War Department, A. G. O., Washington, D. C., July 6, 1897, extended the course of instruction from four to five months, the session beginning as heretofore, on the first Monday in November.

The student officers during the past year are credited with having pursued the course with an interest which gave satisfaction to the Faculty. Nevertheless, it appears to me that better results would be obtained if the class standing of the students at the end of the session were to have weight in determining their relative rank. The work of a student whether good or bad, during the course of instruction, has no effect upon his relative rank, which is at present determined by competitive examination before entering the school. The passage of an Act of Congress giving weight to the course of instruction in determining the lineal rank of officers appointed on the same date would be of such benefit to the School and to the Medical Department of the Army.

Recruiting.—The total number of men examined for enlistment during the calender year was 14,659, of whom 8,654 or 590.35 per 1,000 were accepted, 5,448 or 371.65 per 1,000 were rejected on primary examination and 557 or 38.00 per 1,000 subsequently declined enlistment. The ratio of accepted men per 1,000 of those examined is considerably larger that the rates of previous years. In 1893 the rate was 433.35; in 1894, 451.04; and in 1895, 489.83. This must be regarded as meaning that better men physically are coming up as candidates for enlistment for examination. The rejections among the colored men were relatively somewhat more numerous than among the white candidates for enlistment; 379.00 as compared with 371.04 per 1,000 respectively. The report contains some interesting anthropometric data, showing that although the foreign born recruit has the advantage over the native white in weight and chest measurement, the latter is taller by half an inch.

Physical examination of cadets, United States' Military Academy.—The report of a medical examining board convened at West Point, N. Y., Aug. 20, 1894, indicated that ten cadets had become affected with heart disease while at the Military Academy. The usual character of the disease as reported was said to be aortic obstruction. The board found these cadets "physically disqualified," but recommendation was made that they be continued at the Academy on probation for six months, and Major George H. Torney was directed to make a careful investigation of the cases. As a result of continued observation the conclusion was reached "that in all except one case the murmur heard in each individual at the time of the examination of these cadets in 1894 was due to temporary irritability of the heart caused by the nervous excitement attending the ordeal of examination.

Identification of deserters and other undesirable men.—This system continues to be an excellent safeguard to the Army. There are now in the files of this office data sufficient for the identification of 12,640 men whose records show them to be undesirable associates for honorable young men serving in the ranks and who can be denied enlistment as soon as their cards are received from the recruiting office.

Medical Department of the National Guard.—No medical officer of the Army was on duty during the year with troops of the National Guard, but the meeting of the Association of Military Surgeons in Columbus, Ohio, afforded an opportunity to many of our medical officers of forming a professional and social acquaintance with delegates and others belonging to the Medical Staff of the National Guard of many of the States.

The second Pan-American Medical Congress was held in the City of Mexico, Nov. 16-19, 1896. Colonel Charles H. Alden, Assistant Surgeon-General, in his report of the meeting, gives a general view of the proceedings of this important medical congress and of the advantages derived from it. He pays a graceful tribute to the high standard of the medical profession in Mexico and makes brief but suggestive mention of the great sanitary improvement in progress and of the excellent condition and advanced equipment of its hospitals, schools, laboratories, etc.

Uniformity in medico-military statistics.—Embodied in the report are the data concerning recruiting and the movements of sick in our army, tabulated on the forms suggested by the International Commission which met at Buda-Pesth in 1894.

Health of the Army.—The health of the Army has been excellent during the calendar year 1896, the medical statistics of which are embodied in the present report. In the previous year all the rates that are usually considered by statisticians and health officers as throwing light on the physical condition of a community were lower than any former year of the history of our Army. Practically the rates of 1895 and 1896 are the same, but when accurate expression is given to them in figures those of 1895 continue to be the standard of comparison as the lowest recorded rates.

The admissions to sick report per 1,000 of strength were 1,110.39 as compared with 1,110.22 in the previous year, and with 1,037.73 in 1894, which was the lowest recorded admission rate for all causes; but it is to be observed that an excess of injuries in the past two years raised the total rate, while the admission rate for disease in both years was lower than in 1894, 65 during the past year, 837.53 in 1895 and 845.52 in 1894. average length of time each case was under treatment was 9 days, as compared with 11.14 in 1895 and 11.69 as the rage of the previous decade. The number of days lost on ount of sickness for each man in the Army was 12.43 days, compared with 12.37 in the previous year and 14.93 the average of the previous decade. The number constantly non-effective per 1,000 of strength was 33.97 as compared with 33.89 in 1895. The non-effective rate during the decade prior to 1895 averaged 40.92 per 1,000 of strength. The discharge rate for disability was 10.15 per 1,000 of strength, as against 9.15 the previous year; but that the lessened non-efficiency of recent years does not result from discharging men for disability is easily recognized when we observe that the discharge rate of the decade prior to 1895 was 21.77 per 1,000 of strength. In those ten years a higher non-efficient rate prevailed, notwithstanding the considerably larger number of men discharged from the ranks on account of persisting disability. The death rate from all causes constituted 5.44 per 1,000 of the strength, not much higher than that of the previous year and much lower than the average annual rate, 7.5 of the previous ten years. The corresponding rates from disease were 3.83, 3.55 and 5.10: from injury 1.62, 1.61 and 2.41.

It may be well to notice the great improvement that has taken place in the past few years in the sanitary condition of the colored troops, as manifested by their lessened rates of sickness, disability and death. The white troops have participated in the improvement, although their rates have not fallen so rapidly as those of the colored men. There was no doubt greater room for improvement in the sanitary status of the colored troops and the men may have responded with more earnestness to efforts in this direction. During the past year the total admission rate *for all causes among the colored troops* was 868.88 per 1,000 of strength, as compared with 1,132.49 among the whites for the same year, and as compared with 915.88 among themselves in the previous year, and with 1,368.61 their own annual average for the previous decade, the annual average of the white troops having been 1,284.95. The non-efficiency from all causes among the colored troops during the year was 25.75 per 1,000 of strength, as compared with 34.72 among the white troops. The colored soldier lost 9.42 days from disability during the year, the white soldier 12.71; and the average time of treatment of each case was among the colored troops 10.84 days, among the white 11.22 days. The causes of disability from which the colored men suffered less than the white troops were malarial fevers, venereal diseases, alcoholism, diarrhea and injuries; those from which they suffered more were neuralgia, rheumatism and myalgia, tonsillitis, colic and constipation, conjunctivitis and pneumonia.

Health of the Military Departments.—The admission rate varied in the different Military Departments from 1,246.37 per 1,000 of strength in the Department of the East to 762.18 in the Department of California. It was above the Army average in the Departments of the East, Texas and the Platte, the Colorado and the Missouri; but this was offset by lessened rates in the Departments of the Columbia, Dakota and California.

The rate of non-efficiency or constant disability was above the Army average of 33.97 per 1,000 of strength in three of the departments, the Missouri, Texas and the Platte, but the highest rate, that of the Department of the Missouri, was only 37.23. The rates in the Departments of the East and the Colorado were below the average, but above 30 per 1,000 of each command. Those of the Departments of Dakota, the Columbia and California were below 30 per 1,000, that of California, the lowest, being only 24.02.

The death rate in the Department of Texas, 9.28 per 1,000 of strength, was considerably higher than the average of the Army, 5.44. This rate in the Departments of the Missouri, the Colorado and the Platte was slightly above the average, while in the Departments of Dakota, the East, California and the Columbia it was below the average, the rate of the last mentioned department being only 2.01 per 1,000 of strength.

The rates of discharge for disability varied from 12.29 per 1,000 of strength in the Department of Dakota to 7.15 in the Department of California, as compared with the Army average of 10 15. In three of the other Departments, Texas, the Colorado and the Missouri, the rates were above the average; in the Departments of the Platte, the East and Columbia they were below the average.

Considering all the rates for the calendar year the Department of Texas had probably the worst record and the Department of California the best record among the military departments.

The highest and lowest rates at individual posts.—The largest admission rates for the year were reported from Washington Barracks, D. C., and Fort Myer, Va., 2,250.71 and 2,250.00 respectively per 1,000 of strength. These two posts have had high rates for a number of years. Malarial infection was the principal cause of these high rates. An investigation was made during the past year by Surgeon W. Reed, who concluded that the fevers at both posts were to be attributed to the marsh lands of the Potomac valley. His report was published in my last annual report, page 66. The malarial rate continued high at Washington Barracks during the past year, but the cases at Fort Myer were relatively not so numerous. These two posts, although heading the list of sickness as represented by frequency of admissions, take only the twelfth and fifteenth place respectively when the posts are arranged in order of non efficiency from sickness. Following Fort Myer in frequency of entries on the sick report are Fort Clark and Camp Eagle Pass, Texas, each with over 1,900 entries per 1,000 of strength; Fort Slocum, N. Y., and Fort D. A. Russell, Wyo., with over 1,600, and Fort Riley, Kansas, Fort Monroe, Va., Jefferson Barracks, Mo., Fort Wingate, N. M., and Fort Barrancas, Fla., with over 1,500. The causation of these rates are stated in discussing the health of the Departments. Jefferson Barracks, Mo., had the highest rate, 67.23, of constant sickness, although only ninth in frequency of admissions. This was owing to the prolonged duration of its fever cases, malarial and typhoid. Two other posts, Camp Eagle Pass and Fort McIntosh, Texas, had a constant sickness of over 60 per 1,000 of strength. *Three posts, Fort Barrancas, Fla., Fort Thomas,* Ky., and San Diego Barracks, Cal., had each over 5 per cent of constant non-efficiency. Following these in the order of diminishing rates, are Forts Clark and Brown, Texas, Fort Wingate, N. M., Fort Crook, Neb., Fort Monroe, Va., and Washington Barracks, D. C., the last with a rate of 41.51 for the year. Fort Yellowstone, Wyo., had the best medical record during the year, it having had the lowest admission and non-efficient rates, with no death and no discharge. Its admission rate was 393.15, with less than 1 per cent. of constant sickness, 9.59 per 1,000. Including this garrison there were eight posts which had an admission rate of less than 600: Alcatraz Island, Cal., 477.61, Fort Porter, N. Y., 586.96, Angel Island, Cal., 523.44, Fort Assiniboine, Mont., 540.60, Benicia Barracks, Cal., 540.67, Fort Trumbull, Conn., 558.82, and Fort Wayne, Michigan, 568.00. Sandy Hook Proving Ground, N. J., had less than 1 per cent. of constant sickness, 9.71 per 1,000; Benicia Barracks, Cal., had 13.96, and the large post, Fort Assiniboine, Mont., 1812.

Typhoid fever.—The admission rate for typhoid fever, 5.89 per 1,000 of strength, with a non-efficiency of .85, is an increase over the rates of the previous year, which were 4.32 and .67. The absolute number of cases was 148, of which 17 were fatal. The largest number of cases occurred at Fort Brady, Mich., 15, with 1 sent in from the field; 12 were reported from Fort Logan, Colo., 11 from Fort Sam Houston, Texas, 10 from Jefferson Barracks, Mo., 8 from Fort Sill, Okla., and 7 from Fort Custer, Mont. The remaining cases were scattered, one, two or more at each of forty-two different posts.

With the view of aiding in the diagnosis of doubtful febrile cases, and of determining at the same time the diagnostic value of the changes in the bacilli of typhoid fever when mixed with the blood of a typhoid fever patient, medical officers were requested to forward to this office samples of blood from cases of fever, together with a clinical record of each case to date, and to follow these with a special report of the further progress of the case on its completion. Microscopic slides in slide boxes were sent to each of the posts, with directions for obtaining and mailing the samples of blood. On the arrival of each sample at this office it was sent for examination to Dr. Walter Reed at the bacteriologic laboratory of the Army Medical Museum. The clinical records were not submitted to Dr. Reed, but were retained in this office for consideration in connection with the laboratory results reported. The diagnostic method adopted was that brought into practical use by Dr. Wyatt Johnston of the Provincial Board of Health of Quebec. This method depends on the action of a weak aqueous solution of the suspected dried blood upon a culture of the typhoid bacillus grown in a liquid medium. Observtions were made on the blood of 71 cases of disease. In 27 well-defined cases of typhoid fever positive results were obtained in 25. A negative result was furnished by one case, which gave positive results with serum of a blister. In one case incomplete were followed by negative reactions. In 19 cases of well defined diseases, not fevers, negative results were obtained. From the results in these 46 cases a positive reaction would be strongly suggestive of the presence of typhoid, while a negative reaction would require to be sustained and verified at a later date to show that typhoid was probably not present. There remained 25 febrile cases in which observations were made. In 19 of these the symptoms were not characteristic of typhoid fever. These were, with one exception, cases of so-called Florida fever and Texas fever; but each of these cases gave positive reactions in the laboratory, and it is extremely probable that they were in fact cases of typhoid infection. In 4 of the remaining cases the reactions were negative, but the clinical records were indefinite. The single remaining case, regarded clinically as a remittent fever, was the only case of fever probably not typhoid in which a doubtful reaction was obtained.

Malarial infections.—The admission rate for malarial infections for the year was 83.08 and the rate of nonefficiency 1.65, as compared with 82.56 and 1.70 in 1895, and with 96.67 and 2.48 as the average of the decade 1885-94. The total number of cases was 2,087, of which 1,771 were intermittents, 297 remittents and continued malarial fevers, 1 pernicious and 18 registered as malarial cachexia. One death and one discharge were occasioned by these diseases. The admission rate for the colored troops was 16.63, for the white troops 89.16.

The posts which had high rates were mostly Eastern posts, Washington Barracks, D. C., and Fort Myer, Va., being at the head of the list with 1,071.22 and 644.37 respectively, giving 9.82 and 5.83 of nonefficiency. Jefferson Barracks, Mo., followed with 356.52 and the high nonefficient rate of 16.05. Fort Sill was the only Western post that had a rate, 290.64, approaching those found at these Eastern stations. Forts Clark and McIntosh, Texas, which formerly had large rates, reported during the year only 13.48 and 16.81 admissions respectively per 1,000 of strength. Even Fort Brown had only 90.09 and Fort Ringgold 103.17.

Diarrheal diseases.—The admission rate for diarrheal diseases was 80.02, as compared with 85.14 during the previous year, and with 121.64 the annual average of the preceding decade. The colored troops have participated in this progressive relief from diarrheal attacks to a greater extent than the white troops, their rate for the past year having been only 48.93. Fifty-four cases of acute dysentery with no death, and three of chronic dysentery with one discharge for disability, are included in these diarrheal cases.

Venereal diseases.—The admission rate for these diseases, 78.08, was higher than in 1895, when it was 73.72, while the rate for the previous decade was 76.92. As the rates have been practically stationary for more than a dozen years, we may infer that the minimum prevalence of these diseases under existing conditions has been reached. The slight increase during the past year affected the white troops only. The rates for the colored troops fell from an average annual rate of 80.64 for the decade to 56.53 for the year.

Alcoholism.—The admission rate for alcoholism was 29.06 for the Army as a whole: 31.20 among the white, and 5.70 among the colored troops. Seven deaths among the whites were due directly to this cause. This is a slight improvement on the record of 1895, which shows 30.11 as the rate for the Army, with 32.16 and 6.47 for the white and colored respectively.

Rheumatic affections.—The admission rate for these affections, including rheumatic fever, muscular rheumatism and myalgia, and chronic rheumatic arthritis, was 59.68 per 1,000 of strength; the rate for the colored troops being 71.26, and for the white troops 58.61. The Army rate for 1895 was 61.08, and the average annual rate of the preceding decade 79.33, so that the past year compares favorably in this respect with former records.

Tuberculosis of the lungs.—During the year there were 40 cases of tuberculosis of the lung, resulting in 34 discharges for disability and 6 deaths. These gave an admission rate of 1.59. Among the white troops this rate was 1.52; among the colored troops 2.38, while the respective discharge rates were 1.08 and 3.17, and the death rates .20 and .45. This is an improvement on the previous year, when the admission rate was 2.42, and on the annual average of the previous ten years when it was 3.24.

Pneumonia and pleurisy.—Fifty cases of croupous pneumonia, 7 fatal, were admitted to sick report during the year, the average duration of each case being 29.1 days. Sixteen cases of catarrhal pneumonia, 2 fatal, were also recorded, their average duration 45.1 days. Thirty-seven cases of pleurisy, 2 of which resulted in discharge for disability were recorded during the year. This was a great improvement on the previous year, when 71 cases with 2 deaths and 2 discharges were reported.

Injuries.—The admissions for injuries during the year were equivalent to 279.75 per 1,000 of strength with 8.73 constantly disabled, 1.62 deaths and 2.02 discharges on account of permanent disability. These differed but little from the rates of the previous year. Admission 272.69; nonefficient 8.46; death 1.61; discharge 2.34.

More than one-half of the injuries consisted of contusions and sprains, giving a constant disability of 3.32 per 1,000 men. Ninety dislocations were reported and 193 fractures not gunshot; 7 of the latter were fatal and 8 were discharged for permanent disability. Fifty-three cases of gunshot wounds were reported, 14 of which died and 10 were discharged on surgeons' certificates. There were 93 cases of exhaustion from fatigue or exposure, 23 of sunstroke and 47 of frostbite; none of these were fatal. Seventy-six hernial cases occurred during the year, 16 of which were discharged for disability. Only 12 cases of suicide were reported as having occurred during the year as compared with 19 during the previous year.

Influence of age, arm of service, nativity and length of service on susceptibility to disease.—Table xvii of the report consolidates the medical statistics of the army for the past seven years 1890-96 inclusive, and gives under the various headings the mean annual rates for that period. The ratios are those of admission, constant sickness, discharge and death for officers and enlisted men separately. They are arranged for various diseases and classes of disabling causes, according 1st, to corps or arm of service; 2d, to age by periods of five years; 3d, to nativity, and 4th, to length of service. Many interesting points connected with the prevalence of disease are brought out by the study of this table.

Medical and surgical reports and operations.—The report gives lists of special reports on medical and surgical subjects, with extracts from some of those that are of general professional interest. Many valuable reports of surgical cases and operations are also submitted.

Radical cure of hernia.—During the past two years 79 cases have been operated on by army surgeons. The history of each case has been followed as far as possible to date with the development so far of three instances of recurrence. In one a second operation was performed with success; in the two others the men declined further operation and were discharged for disability. In both instances the phlebitis affected the left leg, the operation having been performed on the opposite side. In one the disease was mild and did not delay convalescence: in the other the phlebitis became developed afterward in the right internal saphenous vein and the man was discharged for disability about six months after the operation.

SANITARY CONDITION OF THE ARMY.

Quarters.—The quarters provided for the enlisted men of our Army at posts recently built are excellent in their sanitary arrangements. At some of the old posts the buildings are more or less in want of repair, some times over crowded, with inadequate ventilation and primitive methods for the removal of wastes. Every year, however, shows some improvement in the condition of these posts. It is to the credit of those concerned that when attention is called to remediable sanitary faults by the monthly reports of the medical officer, immediate action is taken by the commanding officer if it lies within his power, or by an allotment of money for the purpose by the Quartermaster's Department.

On account of the insanitary condition of the quarters occupied by married soldiers at many of our posts, I recommend a return so far to former methods as to provide public quarters for a limited number of married men in each organization, all others being strictly prohibited from having their families at the post. A provision of this kind would be regarded as a privilege awarded to deserving soldiers, and would permit the whole of the huts and shanties now occupied to be destroyed.

Drainage and sewerage.—Local defects in drainage with increase of malarial fevers, tonsillitis and catarrhal affections of the air passages, were reported from several posts. In most instances remedial measures were promptly instituted. Privy pits still continue in existence. Dry earth closets are being substituted for them at Fort Keogh, Mont. The dry earth system gives satisfaction at military posts, but the utmost care is needful in carrying out the details. Some faults in plumbing were discovered and remedied. Improvements in the systems of sewerage have been effected at many posts.

Water supplies.—The water supplies of our military posts have been carefully studied by medical officers with the view of preventing the occurrence of typhoid fever. It is not possible to indicate in a synopsis the many points of interest upon which reports have been submitted. Commanding officers have favorably endorsed the recommendations in the reports of their local medical officers, and the Quartermaster's Department has carried into effect many suggestions for improvement.

Food.—The rations of the men have been reported during the year as ample in quantity, well cooked and of excellent quality. The milk supply of two posts was criticised adversely, and the reports in these instances are suggestive of the possibility of similar conditions at other stations. The Emergency ration was tested by Surgeon Charles Smart on field service with Troop E, First Cavalry, in Oklahoma. A full report on the subject was submitted, showing the success of the expedition in proving the value of the ration in sustaining the men under conditions of emergency and recommending that troops should be accustomed to its use when out from their permanent stations on practice marches and field maneuvers.

Clothing.—The clothing issued appears to give general satisfaction. Greater care is suggested by one medical officer in fitting the men with shoes. His recommendation is that on the enlistment of a man the company shoemaker should measure the man's foot, that a record should be kept of this measurement and that on drawing shoes this measurement should be adhered to.

Personal cleanliness.—Much has been done in the past few years to improve the facilities of the men for bathing, so that during the past year only one post, Fort Du Chesne, Utah, has attracted attention in this regard. Respectfully submitted,

GEORGE M. STERNBERG,
HON. RUSSELL A. ALGER, Surgeon-General U. S. Army.
Secretary of War.

PRACTICAL NOTES.

Formalin in Herpes Tonsurans.—Vidal of Barcelona observed the commencement of a new growth of normal hair in a week with five local treatments with 40 per cent. formalin.—*Wien. Klin. Woch.*, August 5.

Ovarian Extract in Basedow's Disease.—Three cases of Basedow's disease evidently connected with ovarian atrophy or hypoplasia, rapidly improved by the ingestion of ovarian extract, are reported by L. Seeligmann, *Semaine Méd.*, August 4.

Effective Sterilization of Catgut and Silk with Sublimate and Ether.—A French army surgeon, Dr. Merlin, announces that a 1 per cent. solution of sublimate and ether renders catgut, silk and silkworm guts absolutely aseptic, while not detracting in the least from their flexibility or strength.—*Dauphine Méd.*, No. 7.

Iodized Peptone, Substitute for Iodoform.—The action of metallic iodin on peptone produces a brown soluble powder, powerful odorless antiseptic, and an efficient substitute for iodoform, according to V. P. Garmachew. It sterilizes pus in fifteen minutes, and kills anthrax cultures in an hour at the proportion of a tenth; favors cicatrization, etc.—*Semaine Méd.*, August 4.

Prevention and Curability of Deafnesss and Dumbness.—If the ear troubles of infants are not attended to promptly they may become chronic and terminate in total deafness, not recognized for a long while, as the infant is too young to talk. This is the etiology of many cases of deafness and dumbness, according to Verdos, which could have been prevented by local treatment in time.—*Archivos Latinos de Rhin.*, etc., No. 73, 1897, in *Presse Méd.*, August 12.

Iodoformed Ether in Hydrocele.—The technique of the injections of 10 per cent. iodoformed ether, with which Reclus has been so successful in hydrocele, is very simple. The hydrocele is first punctured or lanced and the serosity allowed to escape, after which he injects 3 to 8 c.c., with a Pravaz syringe of corresponding size. There is no pain and the patient can resume his usual life and occupations the same day.—*Presse Méd.* July 31.

Nutritive Value of Subcutaneous Injections of Oil.—It is reported from Turin that 30 to 200 grams of olive oil injected into the subcutaneous tissues are absorbed rapidly and effectively, serving as nutriment, as evidenced by the increase in weight and general well being. This method of alimentation is therefore recommended whenever rectal alimentation is necessary. It reduces the amount of nitrogen eliminated, and has proved especially effective in two cases of diabetes.—*Semaine Méd.* July 28.

Alkalines Required to Destroy the Pneumococcus.—The danger of infection of the meninges from ocular affections due to the pneumococcus is shown once more by a case reported by de Lapersonne, in which fatal meningitis followed enucleation of an eye on account of traumatism in a child. The pneumococcus is not destroyed by most antiseptics; sublimate, for instance, does not dissolve its capsule. He has found most effective a solution of chlorinated lime, 1 to 60, which he recommends for the purpose.—*Nord Méd.*, August 1.

Gastro-Jejunostomy for the Relief of Gastrectasis.—In a communication presented to the Missouri State Medical Society, Cordier (*Medical Record*, Sept. 25, 1897, p. 441) offers the following conclusions: 1, carcinoma of the pylorus, even though removed, returns quickly and always kills; 2, pylorectomy is attended with a high mortality and is not a justifiable surgical procedure in cases of advanced carcinoma of the pylorus; 3, gastrectatis due to malignant closure of the pylorus is best treated by gastro jejunostomy; 4, the operation advised by von Hacker best meets the indications; 5, it is not necessary to twist the bowel in making an anastomosis to prevent bile from entering the stomach; 6, the anastomotic opening in the stomach should be at the most dependent point of the dilated organ; 7, the operation is attended with a low mortality; 8, in all cases in which marked dilatation of the stomach exists and is accompanied by emaciation, pain and invalidity, the operation of gastro jejunostomy should be performed; 9, the relief of pain due to the effort of the stomach to relieve itself follows this procedure at once, the patient gains rapidly in weight, and if non-malignant disease be present his former good health is restored.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the *Editor*, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, OCTOBER 16, 1897.

THE INFLUENCE OF THE SANITARIAN IN THE EXPLORATION AND COLONIZATION OF TROPICAL COUNTRIES.

The important rôle played by bacteriology and hygiene in the successful exploration, development and colonization of the tropic countries is a subject sometimes neglected in the literature from these regions. Side by side with the bold navigator, the intrepid explorer, and the persistent engineer, the sanitarian has worked to rescue the riches of the unknown tropics for the overcrowded and overworked inhabitants of civilization.

Reviewing the subject of colonization from its earliest times, we are struck with the comparative ease and freedom from danger with which the emigrant of today accustoms himself to his new surroundings. Before the dawn of scientific medicine the frightful mortality among the early colonists forbade all but those of the most reckless natures to leave their homes to face what seemed almost certain death. The substantial, purposeful emigrant, the true backbone of a successful colony, turned from the tropics to less profitable but more salubrious climates. There has been a recent disposition to credit the pioneers in engineering and road-building with the glory of having opened the dark continents to commerce and colonization, but without the knowledge and practical advice of the sanitarians they would have all been gathered to their fathers long before their plans were beginning actualities.

In the early days the few foreigners who were spared to live in the tropics were supposed to have undergone an especial adaptation or acclimatization; and it is interesting to study to what extent such immunity is possible. The atmospheric element of danger in the tropics can be partly overcome by prudence in early exposure and certain protective measures, and the system may become gradually habituated to its new physical environments by a species of adaptation in which the whole physiologic organization is modified. But with the first generation at least this acclimatization is very superficial and ephemeral, as any marked indiscretion or fatigue destroys the new equilibrium.

Turning to the consideration of the early means of protection against the pathologic elements of danger, we find that the only immunity was that acquired by recovery from a first attack of certain infections, such as yellow fever; but this immunity does not hold good for the great majority of tropical diseases; in fact the more common diseases are of a distinctly relapsing type. It is thus easy to see the shortcomings of the natural protection by acclimatization. It was only after frightful mortalities through several generations that a race was evolved adapted to its surroundings.

With our modern bacteriologic and hygienic knowledge we are supplied with the means of what, for all practical purposes, is the equivalent of an immediate adaptation. By observing the prophylactic laws of living evolved from a patient study of tropical hygiene, and by bacteriologic examination of the aliments and soils, the colonist is protected against a great number of tropical diseases. The mortality from dysentery has greatly diminished among colonists furnished with potable water. Defective alimentation is the cause of many colonists' diseases, such as scurvy and beri-beri, both of which may be prevented by dietary regulation. With modern means of transport insufficiency of the necessary variety of food is inexcusable. The first instructions of the tropical emigrant of today are in personal and public sanitation and the advice and services of the scientific sanitarian are the most valuable in the establishment of a tropical colony.

The struggle against malarial infections is the most difficult; but here again the sanitarian and therapeutist are slowly depriving this plague of its horrors. More healthful building sites are chosen, pure water supplied, stringent prophylactic measures instituted and abundant medicaments furnished. Extra care and intervals of rest are given to men working in recent excavations and in the malarious lowlands.

To one unfamiliar with the recent sanitary reforms in the tropics the good results therefrom are astonishing. According to statements made by M. FIRKET of Liége in the discussion of the colonization of the Congo Country, before the International Congress of Hygiene and Climatology, in Brussels, August, 1897, by the application of vigorous sanitary measures, the mortality in certain African colonies has fallen from 85 in 1,000 for the English and 170 in 1,000 for the

the University of St. Andrews. The Medical Departments of these Universities, St. Mungo's College, Glasgow. Anderson's College Medical School, Glasgow, and the University College, Dundee, are alone entitled to confer degrees in Scotland to men.

So far as the general statement that a patient with retention of the urine had a diagnosis made by somebody—of carcinoma of the stomach—and that the said patient was subsequently relieved by the passage of a catheter, is no particular argument in favor of osteopathy, because it is wholly irrelevant to the subject matter. We never denied it. We regard osteopathy as an unmitigated humbug and its practitioners as obtaining money under false pretenses. That is our opinion.

CORRESPONDENCE.

Pyrethrum.

Key West, Fla., Sept. 20, 1897.

To the Editor:—Will some reader of the Journal having the facilities, administer to dogs, etc., different doses of insect powder and report results? Through an accident to a child it was found to possess probably anthelmintic properties, and I would like to gain some idea of its dosage for *homo sapiens*, from trials on the lower animals. Insect powder consists of the flowers of Pyrethrum carneum and P. roseum, indigenous to the Caucasian Mountains, but now extensively cultivated in California. It is frequently adulterated and I would ask whoever undertakes this investigation to get a perfectly pure article. The fumes of the burning powder are not poisonous to man, though it causes some confusion of the head in those who sleep in closed rooms where it is used, and the writer has seen in the case of a man sleeping in an apartment completely closed and filled with the smoke considerable intoxication, numbness and severe itching in the upper and lower extremities, which persisted for several hours. In a patient who contracted the mange or acarus scabiei from a horse, dry insect powder applied to the skin afforded more relief and limited the spread of the insects better than a dozen other remedies previously employed.

In the dry state it destroys insects infecting man, beast, bedding, etc., and is used as a dressing for ulcers and wounds. According to the "U. S. D." the powder exhausted by alcohol is harmless to insects, its activity is therefore dependent on some principle whose nature has not positively been determined. Professor Riley, in a series of experiments, found the fumes of the burning powder very poisonous to insects and for certain purposes (mosquitoes, midges, sand flies, etc.) afforded a ready mode of application, but that generally a watery infusion was the best and cheapest preparation. Twenty-five grains stirred up in two quarts of water was sufficient to kill young cotton worms. The tincture (one part to four) has been especially recommended, diluted with ten times its bulk of water, by F. Jager to keep off vermin from the human body. According to Professor Maisch, it is capable of causing a vesicular eruption like that produced by poisoning. Pyrethrum is certainly a blessing in the tropics in combating the mosquito (sometimes written mosquita) a Spanish word signifying "little fly." G. R. Plummer, M.D.

Severe Epistaxis.

Thurber, Texas, Oct. 6, 1897.

To the Editor:—I wish to report in brief a severe case of epistaxis that occurred in my practice last week. I was called to see a young man aged 26, at 10 p.m., to stop a very severe nose-bleed from the right nostril. He has a large polypus in that nostril, which I judge to be the cause of the hemorrhage. With Dr. Chas. Binney, who was also called, I soon plugged the nose anteriorly and posteriorly with cotton, also insufflated tannic acid into the bleeding nostril and left, feeling satisfied that he would not be troubled any more that night. Dr. Binney sent for me at six in the morning and informed me that he had been with the patient nearly all night. He could stop the bleeding, but in a short time it would commence again by the blood flowing into the throat. During the day we used Monsel's solution, antipyrin, etc., but could not check the flow. At 3 o'clock in the afternoon, seventeen hours after the epistaxis commenced, our patient was pulseless and almost moribund. We decided at that time to try an oil on the cotton to prevent the oozing of blood through the cotton. We removed the plug, and supplied plugs posteriorly and anteriorly that had been previously saturated in liquid albolene and the hemorrhage stopped never to return. This idea at the time was entirely original with me. It may be known and practiced, but I am confident it is not generally known. I know of two deaths from epistaxis in which a specialist officiated and in neither was oil applied to the plugs. I have also examined eleven text-books on the subject and find only one mentions the use of an oil in the treatment of epistaxis. In the "System of Surgery," by Dennis, I find, "a tampon of cotton, lint, or sponge, saturated with vaselin, should have previously been prepared, etc." He does not say for what the vaselin is used and one would imagine it was merely to lubricate the tampon to facilitate its introduction. I think it important to saturate the cotton with albolene, vaselin or any light oil to prevent the blood from oozing through the tampon.

I do not write this with the idea of presenting anything new, but merely to impress it on those members of the profession who do not know, that they may not be so unfortunate as to lose a patient from nosebleed. T. M. Baird, M.D.

Underground Zoology and Legal Medicine.

Washington, D. C., Sept. 28, 1897.

To the Editor:—Will you allow me to correct, in several important particulars, the rather mixed report on page 616 of the current issue of the Journal of my paper on "Underground Zoology and Legal Medicine," read before the public medicine section of the British Medical Association on the 1st inst. The facts that "the subject is a new one and medicolegally interesting," if not important, warrant me, I feel, in seeking a correct statement of my observations.

1. I found the same species of mites, beetles and flies on cadavers buried for periods varying from two to ten and even twenty years. Thus showing that *under the conditions here observed*, these scavengers do not seek the buried cadaver in distinct "squads" nor at definite periods.

2. I found certain species of flies (other than the phoridæ) on cadavers buried in midwinter, as well as on those buried in midsummer. The conclusion, therefore, that the finding of dipterous remains on a cadaver is proof of burial during the summer months is not in all cases a safe one.

3. My studies made primarily to test for this locality, Megnin's application of entomology to legal medicine had little to do with the persistent vitality of pathogenic organisms. In one case of tetanus, however, the cadaver having been buried for ten years and seven months, a guinea pig inoculated with material from the coffin died, but *without* showing any symptoms of tetanus or any trace of the tetanus bacillus.

The main point to be noted is that the entomologic chronology of cadaveric history has not yet been clearly established; nor can it be without further extensive observations and comparison of results in different localities. This caution was well uttered by Johnston and Villeneuve in the *Montreal Medical Journal*, August, 1897.

Murray Galt Motter.

Suppressio Veri; Suggestio Falsi.

St. Louis, Mo., Oct. 9, 1897.

To the Editor:—In consideration of the above and the correspondence between Drs. Woodbridge and Upshur, I propose to give a brief sketch of my experience in typhoid fever in Missouri for over forty years.

In the fall of 1853 I had charge of a family of seventeen persons, in age ranging from 1 to 20 years (Dr. C's. family). Called in consultation Dr. McD., a graduate of a Philadelphia medical college. We diagnosed typhoid fever in case one. The patient was about 20 years of age, of sanguine temperament and good health up to that time. Treatment began with a purgative dose of calomel, hot turpentine stupes over the bowels (right iliac region), aromatic sulph. acid as a drink, and Dover's powder at night. The diarrhea was kept within reasonable bounds by the two latter, increasing or lessening the amount according to circumstances. After his bowels were moved from the first purgative, we gave from ½ to 2 grs. calomel every six hours. About the ninth day his tongue had cleaned and become moist. Tympanites and some pain subsided over bowels and he was convalescing rapidly, but contrary to orders he got up, dressed, and persisted in walking about his room. In the afternoon he was seized with a severe hemorrhage and within a period of about three hours died from perforation of the bowels (supposed). There is nothing out of the ordinary in this case. The unexpected termination, and the alarming condition of the remaining sixteen called for the most deliberate and philosophic consideration. All had diarrhea, some were in bed, others preparing to go, and all without exception presented unmistakable evidences of type with the case above.

I proposed calomel in small doses as a curative and prophylactic. It was opposed on the ground of its constitutional effects. I referred the other two doctors to the old axiom, "Abusus non tollit risum" and began by giving calomel ¼ to 2 grs. every four, six and eight hours, alternately with permanganate of pot. in similar doses. This treatment was given, with some variations, to the entire family of sixteen. All made good recoveries and in about three weeks were discharged.

In summing up the treatment which I have invariably practiced, I wish to emphasize calomel and permanganate potass. (or if preferred as a matter of choice, bichlorid hydr.) in minute doses as a preventive, abortive or curative. Of course the many adjuncts, such a turpentine, arom. sulph. acid, etc., should and ought to be considered in many cases. The constitutional effects of the first named agent should always be sought for as speedily as possible and held there until the patient is beyond all danger of relapse.

In all cases where the stools are particularly offensive (and all are) the permanganate potass. should be continued until the fetor, etc., are corrected and this change is evidence of the destruction of the germs, poison, in other words, typhoid bacillus. In diet: Liquid food, buttermilk, sweet milk, raw eggs beat up with spts. frumenti, soups, etc.

My success in typhoid fever has been so completely satisfactory that I am not disposed to change this described treatment of it for any other.

In this article I wish to place myself on record as endorsing the several articles in the Journal favorable to blood-letting (notably Dr.Todd, San Francisco) in pneumonia, puerpural convulsions, certain conditions of the brain and stomach, etc.

J. M. Foreman, M.D.

Wants the Discussion Continued.

Milton, Del., Oct. 9, 1897.

To the Editor:—We have been watching the controversy which has been going on between Drs. Woodbridge and Upshur, yet it has not been interesting or edifying to your readers for we have been looking for them to say something to confirm the abortive treatment of typhoid fever or *vice versa*. While we have not been able to indorse all that Dr. Woodbridge claims, yet we have reason to believe that there is some good in it and the antiseptics which he uses. We have ever believed in antisepticising of the alimentary canal in every disease, and purging out the accumulation of the ages, following this with some antiseptic remedy. There can never any harm occur from this course, but many, many times great good. But let the doctors comment and criticise each other as they may about the abortive treatment of Dr. W., however good or bad it may be, it will have a tendency to revolutionize the treatment of typhoid fever and that of all others. The agitation of this by Dr. W., if it does nothing else, will cause the subject to be ventilated as perhaps no other has been since my debut into the profession. And whatever subject is gotten up for discussion in any direction will be beneficial and bring out and develop the truth. We say go on Doctors, but let us have less of your spleen and more of the cause and treatment of typhoid fever.

James A. Hopkins, M.D.

Hospital Interneships.

Chicago, Sept. 30, 1897.

To the Editor:—I read with interest your editorial, "The Advantages of Hospital Interneship," in the last number of the Journal.

My opinion is that all agree in acknowledging the benefit of hospital training. Why do more students not secure to themselves the advantages of such a training? Is it a want of appreciation on the part of the prospective physician? I think not.

The average student, yes, 95 per cent., are anxious to secure a place in some good hospital, in fact in any hospital. Place the blame where it belongs. The fact is that there are too few places of this kind to be filled. The case you cite illustrates my point very nicely. You say fourteen students came up for examination to fill twelve vacancies. Out of that fourteen twelve got hospital positions and two were disappointed. Had there been forty come up for the same examination twelve would have gotten places and twenty-eight would have been counted out. That is one reason why more do not make the effort. Another will be found in the fact that those who anticipate taking the examination for hospital interneship devote their last year to "bucking" for examination, as they call it, to the exclusion of hospital and dispensary clinical work. Instruction under the tuition of their teachers is ignored entirely. What then happens to the unfortunate candidate? He finds himself, on graduation day, decidedly short in clinical experience, with but little prospect of getting more before entering active practice, unless he should be so fortunate as to have more money than many of them possess.

This can be remedied to some extent by shortening the period of interneship. If the term was made twelve months instead of eighteen months, just one-half as many more would receive the benefit of a hospital training. There are always more candidates than there are places.

The physicians who control our hospitals are responsible for this and to them should an appeal be made for more internes and shorter service. Yours truly,

A Subscriber.

Death from Carbolic Acid.

Weaverville, N. C., Sept. 23, 1897.

To the Editor:—I report this case as I have not been able to find one in which death took place so soon after taking so small a quantity of carbolic acid.

Mrs. Miles, aged 28, mother of two children, youngest 5 years old, was in the third week of typhoid fever, about the sixteenth day with temperature ranging from 100 degrees in the morning to 101.4 in the afternoon, when the nurse gave her one teaspoonful of carbolic acid (red) in one-fourth glass of water.

In three minutes she was unconscious, her lips and face livid, and muscles rigid.

The nurse gave mustard and warm water without effect, then she was given magnesia, lime-water, sweet oil and raw eggs. In fifteen minutes she was profoundly comatose and would have died of heart failure, but was given, hypodermically, morphin and strychnia, and death took place from the lungs. She was dead in less than forty minutes. W. L. Reagan, M.D.

A Query on Serum Treatment.

Jackson, Tenn., Sept. 9, 1897.

To the Editor:—Since it appears that the serum of the blood taken from those who have typhoid fever will destroy the typhoid bacillus, is it not reasonable to suppose that serum taken from those who have just recovered from the disease and inserted into the blood or tissues of those who have it, may prove a remedy for the disease?

Or, for fear of contamination from the blood of those who had it, may not the typhoid bacillus be injected into the horse or cow and the serum taken from those animals and injected into the blood or tissues of typhoid patients prove to be an antitoxin to the disease? J. A. Crook, M.D.

SOCIETY NEWS.

The American Academy of Railway Surgeons elected the following officers; President, Dr. R. Harvey Reed, Columbus, Ohio; first vice president, Dr. W. J. Mayo, Rochester, Minn.; second vice president, Dr. Arthur D. Bevan, Chicago; secretary, Dr. C. D. Bryant, Omaha. Place of meeting, Chicago, 1898.

The International Congress of Pharmacy, Brussels, August 14 to 19, recommended the institution of a superior council of legal chemistry; also that the usual denomination given to a chemic product cease to be a trade mark or private property after it has fallen into the public domain (referring to products with well-defined formulæ, antipyrin for example). An international committee was appointed to prepare a codex of methods of analyzing for the titration of drugs and Galenic preparations containing definite principles. Professor Remington of Philadelphia delivered an address on "Revision of the Pharmacopeia," with an appeal for concerted action on the part of physicians and druggists, the former agreeing not to prescribe secret formula remedies and the latter agreeing not to manufacture them. Denayer concluded his report on "Organ Extracts," by urging the importance of absolute sterility in the liquid form and absolute freedom from moisture in the powder, tablet, etc., form, kept preferably in dessicators *à la chaux* (lime). All the European countries, the United States and Mexico were well represented. The next congress will convene in Paris in 1900.

Newport (R. I.) Medical Society.—Newport, R. I., Sept. 11, 1897. Dear Doctor:—As chairman of a committee of the Newport Medical Society I am directed to call the attention of all Medical Societies and Journals to the following letter:

At a regular meeting of the Newport Medical Society, held Wednesday, May 19, 1897, the following resolutions were unanimously passed:

Resolved, That it is the opinion of this Society that Congress should change the existing laws regarding the employment of physicians on steamships and other vessels and, with a view to the attainment of that end, the Society deems it advisable that the words "other than ferry boats" be inserted between the words "vessels" and "carrying," which are on the eighth line on the forty-ninth page in Section 5, Chapter 6, Title forty-eight of the "Laws Governing the Steamboat Inspection Service, Revised Statutes of the United States as amended by various Acts of Congress, printed 1896." Also that the word "immigrant" on the ninth line of the same page be erased. Also that the words "or passengers or other than cabin passengers" on the ninth and tenth lines of the same page (forty-ninth) be erased and the words "lying between one inspector's district and another or going foreign" be inserted instead. Also that the word "fifty" be erased and the word "thirty-five" be substituted for it on the tenth line of the forty-ninth page. Also that on the twelfth line between the words "articles" and "and" should be inserted the words "and not required to do other duties that those usually required of a ship's surgeon on government vessels." Also that after the word "dollars" on the twenty-second line on the forty-ninth page should be inserted the words "for each trip or voyage."

Resolved, That the President and Secretary of the Newport Medical Society forward to the President (Dr. Nicholas Senn) of the American Medical Association a copy of these resolutions, and urge in their communication to him the expediency of urgent action on the part of the delegates to the American Medical Association, and also that each delegate shall use all influence with his individual Congressman to attain this very desirable result.

A copy of these resolutions was forwarded to the President of the American Medical Association, with two copies of the "Laws governing the steamboat inspection service," one for the President and one for the Secretary, Dr. W. B. Atkinson, both marked. Our delegate, Dr. Mary E. Baldwin, delivered the resolutions to the Secretary, who informs us that, owing to great pressure of business, they were not brought before the Association by him, expecting that our delegate would present them; and as our delegate expected that they would be presented by the Secretary they were, unfortunately, not presented at all.

At the regular meeting of the Society held the 21st of July, a committee of five was appointed to draw up a letter containing the above resolutions and also to give some data concerning this important matter and to forward them to all medical societies and journals. We can only say (what our Society has often said before) if this great event be brought about that it will give employment to hundreds of competent physicians, open new paths to the younger members of the profession and prove of great practical usefulness and benefit to the traveling public.

On the steamboats between Fall River, Mass., and New York City there are sometimes as many as a thousand passengers on the boat. Although the trip lasts, as a rule, only nine hours, still there are times when the boats are delayed for hours and it seems that it would be more in keeping with the humanity of the times to have a physician on the boat than to have the expense of canary birds and brass bands and that the money would be much better expended if such were the case. All the steamboats on the Sound, on the Great Lakes, on the long rivers where passengers are often for days without medical aid, practice the same economy. Our seagoing steamers running South, as a rule have no physician on board. Some employ the device of employing the purser as surgeon and when he is pressed, owing to his numerous duties, appoint at times a man who is not any more qualified than the purser to act as a surgeon's assistant. Such steamers as those running from Philadelphia to Portland carry often thirty or forty passengers and a crew of twenty or more and being often out three days should have a physician on board. A passenger on one of the lines running South was obliged to act for the company, as a man had a severe injury and could not be put ashore for three days. The passenger was, fortunately, a surgeon. Again, it is very common on all the steamboats to rely upon traveling physicians to care for sick seamen and passengers. They receive no compensation for their services and are not even returned their passage money. Such conduct is inexcusable besides being a great wrong to the public. Invalid physicians, traveling for their health, have been called up to attend to cases and have suffered greatly in consequence of being disturbed of their night's rest. Cases of childbirth on steamers are not infrequent, and the chairman of this committee had a case of childbirth and was up all night, and on another occasion passed a whole afternoon and night with a patient (one of the waiters) who was suffering from a nearly fatal attack of edema of the glottis. In neither case was any remunération given nor was the passage money returned. Another member of this committee has often had to perform duties not only of a medical character, but those of a surgeon. The profession is injured in this way, and it is absurd as well as injurious to the profession to have pursers act as surgeons or surgeons perform duties of a clerkly character, and none of which belong to the duties of a ship's surgeon.

We, therefore, protest against the existence of this abuse any longer, and we call upon our medical brothers throughout the land to aid us in any and all ways to abolish this abuse, to call upon their senators and representatives to aid them in so changing the laws that such abuses shall be abolished and that the long-suffering traveling public and the crews of our vessels shall have at least as much protection as the whalemen have on British ships.

The chairman of this committee called attention to this fact in an article published in the *Newport Daily News*, in 1885. The importance of having a regularly educated physician on board in case of an epidemic of cholera, yellow fever or other plague is beyond dispute to any intelligent mind and should be looked upon as an absolute hygienic requirement.

Dr. V. Mott Francis,
Dr. H. R. Storer,
Dr. F. J. Davis, *Committee.*
Dr. C. W. Stewart,
Dr. Mary E. Baldwin.

V. Mott Francis,
President of the Newport Medical Society.

Mary E. Baldwin, *Secretary.*

August 17, 1897.

Kindly send me a copy of any action that you may decide to take, in print or otherwise, in furtherance of the object indicated. Yours sincerely, V. M. F.

The Twenty-Third Annual Meeting of the Mississippi Valley Medical Association was held in Louisville, October 5 to 8 inclusive. The features of this meeting were excellent and timely papers, lively discussions, liberal entertainment and lovely weather, the whole being enhanced by the prevailing sentiment of Kentucky good fellowship and hospitality. The Association has never been so lavishly entertained as at Louisville, and this city has added another lustrous star to the constellation with which the local profession is already adorned. Many prominent and able men were present, among whom may be mentioned, Senn, Bishop, Goldspohn, Ochsner, Sanger Brown and Murphy of Chicago; Shoemaker and Price of Philadelphia; Morris and Foster of New York. The officers elected for the ensuing year were: John Young Brown, M.D., St. Louis, President; A. P. Buchman, M.D., Fort Wayne, Ind., First Vice-President; A. J. Ochsner, M.D., Chicago, Second Vice-President; Henry E. Tuley, M.D., Louisville, Secretary. A more extended report of the proceedings will appear in a later issue. The next meeting of the Association will be held on the second Tuesday in November, 1898, at Nashville. The most attractive feature of the Medical Exhibit Hall of the Mississippi Valley Medical Association is the Medical Press Bureau, conducted by Charles Wood Fassett, whose long connection with medical journalism and medical society meetings makes him capable of managing an enterprise of this kind. In this bureau were represented a number of the leading medical journals of the country, and a system of sampling and distribution has been inaugurated which is certainly most beneficial to those publishers who are fortunate enough to secure membership. Among the journals represented we notice the following: Journal of the American Medical Association, Chicago; *Annals of Gynecology and Pediatry*, Boston; *Mathews' Quarterly Journal of Rectal and Gastro-intestinal Diseases*, Louisville; *Medical Fortnightly*, St. Louis; *Medical Herald*, St. Joseph; *North Carolina Medical and Surgical Journal*, Wilmington; *Medical Review of Reviews*, New York; *Philadelphia Polyclinic*, Philadelphia; *Virginia Medical Semi-Monthly*, Richmond; *American Medical Journalist*, St. Joseph; *Journal of Eye, Ear and Throat Diseases*, Baltimore; *Daily Lancet*, New York City.

PUBLIC HEALTH.

The Lock-step as a Possible Menace for the spread of contagion has been abolished in the Detroit House of Correction.

False Economy.—The town authorities of Maidstone, Kent, England, are held responsible for the typhoid fever outbreak, owing to their refusal to renew the appointment of a watchman for the water supply at an annual salary of $200.

Health in Michigan.—Reports for September show the five diseases causing most sickness in Michigan for the five weeks ending October 2, to be: rheumatism, diarrhea, neuralgia, bronchitis and influenza. Consumption appears tenth on the list.

Results of Sanitation.—According to the New York Health Board reports for the first eight months of the present year the death rate has been 20.2 to the thousand. This means, in round numbers, 14,200 fewer deaths this year than there were under conditions five years ago; a gain, therefore, of 14,200 in actual population. Naturally much self-complacency may be read between the lines.

Typhoid Fever from a Disused Well.—The *Medical News*, October 2, has an item stating that water drawn from an abandoned well has given rise to several cases of typhoid fever near Rye Beach, N. Y. A party consisting of half a dozen persons went into camp near that place and drank water from an old abandoned well. The whole party immediately became ill, and two of the members have since died.

Yellow Fever in the Havana Hospitals.—According to a report in *La Medicina Militar Española*, during May there were in the yellow fever hospitals of Havana, admitted 814; discharged 406; died 226. During June, admitted 677; died 170; remaining 331. In the general hospitals during May there were admitted 38,692; discharged 33,739; dead 523. During June there were admitted 9,931; discharged 8,798; died 270; remaining July 1 5,512. These are the statistics of the Spanish army of invasion.

Health in Chicago.—During September the total deaths in Chicago were 1,679 or 1.04 per 1,000, as compared to 1.02 per 1,000 for the same period in 1896. Of these, 464 were under 1 year of age, 219 between 1 and 5 years. The leading causes were: Diseases of nervous system, 203; consumption, 175; infantile diarrhea, 152; other acute intestinal diseases, 163; heart diseases, 92; cancer, 76; pneumonia, 67; diphtheria and membranous croup, 53; typhoid fever, 48; bronchitis, 37 (*vide* Journal, September 18, for August report).

Sanitary Inspection Company.—In 1883 a successful company was instituted in London under the name of the London and Surburban Sanitary Survey Association. Last summer a similar corporation was formed in New York, under the title of the Building and Sanitary Inspection Company. It is prepared to make sanitary inspections of buildings and premises, to issue sanitary certificates where the conditions warrant it, to take yearly supervision of buildings, to draw plans for and take charge of all sorts of sanitation work and to make structural examinations of all kinds of property, thus offering services which are of value to owners, occupants, mortgagees, prospective buyers, lessees and investors.

"Silver Wedding" Celebration of the Michigan State Board of Health.—The members of the legislature of Michigan have consented to have Dr. Baker celebrate the twenty-fifth anniversary of the establishment of the State Board of Health on July 30, 1898. They request the State Board to prepare comparative statements of the conditions affecting the public health, and of the actual conditions of health in Michigan before and since its establishment, exhibiting, if it be true, that there is a very marked improvement in the healthfulness of the State in recent years, and statements of the principal dangers to life and health at the present time, and a program for a public meeting for the discussion of measures for the further promotion of the public health in Michigan. They invite the National Conference of State Boards of Health to hold its next annual meeting in Michigan in the summer of 1898, and also invite the Surgeons-General of the Army, Navy, the Bureau of Animal Industry and the Boards of Health of all the principal cities to assist. The Railroad Commissioner and the State Board of Health are asked to act with the citizens to facilitate the attendance of excursionists from other States; to place before the visitors the beauties of the summer resorts on the shores of the Great Lakes and to exhibit Michigan as a summer resort State. Sanitarians will take pleasure in doing their utmost to spread the light and lend a hand, because Michigan has done so much through its Board to show the value of such organizations, and through its honored Secretary has done so much to prove how much can be done by a wide-awake board backed up by a not illiberal legislature.

Disposal of Condemned Meat in London.—In the city of London during 1896 Dr. Saunders, the Medical Officer of Health, had to deal with 915 tons of meat which had been condemned as bad and which, had it not been seized, would have been sold. Contractors paid the commissioners of sewers £2,352 for the evil-smelling stuff. Dr. Saunders, in explaining what is done with it, said that first of all it is hacked and slashed about with knives to render its appearance unlike meat for market, and then it is thrown into a chemic bath to soak for some time. These baths were introduced by Dr. Saunders in 1874. The meat is treated with chlorid of calcium and soda and afterward with sulphate of iron, which renders it black, unsightly and nauseous. It is by this time a pulpy mass of decomposed tissue almost beyond recognition. It is now treated with picric acid, which turns it a bright yellow. At this point the city authorities have done with it and it is given over to the contractors, who remove it to some works at Bow, where in steam-jacketed pans it is boiled down for the fat, which is sold to candle- and soap-makers. The bones are collected and sorted, the smaller and worthless ones are reduced to powder which is sold for phosphates. The residual liquor, which is a thick yellowish-brown fluid, is used as a fertilizer.

Public Health Work in Vermont.—The *Burlington Free Press* quotes from an article by Dr. Ashbel P. Grinnell, in "The New England States," published by Hurd of Boston, the conclusions as to the status of preventive medicine in Vermont. It says: Dr. Grinnell in his discriminating record finds the Green Mountain State deficient in laws relating to the public health, but is hopeful that the State Board of Health with the aid of the local boards and the registration law of 1896, placing the vital statistics of the State in the hands of the State Board and requiring reports of births and deaths from physicians and the safeguards against the disposition of dead bodies, will in no long time remedy the deficiencies. "The Board," he says, "aims to keep the laws of the State in harmony with the recent important discoveries in preventive medicine, to secure their observance by intimate co-operation with local boards throughout the State and relies on the medical profession to give it at all times its hearty support." We are deeply interested in the work of Drs. Grinnell and Lewis and doubt not it will add real value to the great work for which it is prepared. We esteem the doctors of Vermont, with whom we have had long and large acquaintance, not only for their learning and skill in administering medicine, but more for their sympathy and success in mitigating pain and encouraging endurance to overcome distress. They are diligent by day and by night, in sunshine and storm, to overcome the calamities and weaknesses that fall upon their brethren. It is the spirit that is in them, as well as and more than the doses they dole out, that give confidence and lengthened life to the community.

Street Sprinkling with Disinfectants.—For some time the municipal authorities of the city of Brussels have endeavored to find a system for watering the public streets with a disinfectant. Mr. Van Hersten, the director of the Brussels slaughter house, has for the past four years used an apparatus of his invention for cleaning out the piggeries, stables, market and courts of said establishment. On February 23 an experiment made with said apparatus for street sprinkling proved so successful that the city of Brussels is disposed to definitely adopt the system. The apparatus, which is very simple, is composed of a cylindric reservoir which is filled with an antiseptic substance, creolin preferred. A pump system is applied to the reservoir, which produces when the city water is introduced into the apparatus an aspiration more or less strong, which is regulated at will. The antiseptic matter mixes with the city water and thus changed acts as an efficacious disinfectant. This apparatus was especially useful a few years ago during the aphthous stomatitis epidemic in Belgium. While a few sporadic cases are reported in this country, an epidemic of the disease now exists in the neighboring kingdom of Holland. During the month of January, 1897, the aphthous stomatitis was reported in 380 cattle stables in Holland, distributed over 110 communes. The number of cattle infected was over eleven thousand. In one locality in the province of Drenthe, sixty-two stables, numbering nearly three thousand animals, were contaminated, and the epidemic up to this writing is still prevailing. Although the disease, aphthous stomatitis, is reported as decreasing, it has appeared during the past fifteen days in seventy-nine cattle stables, principally in the provinces of Brabant and Hainaut, and also among the cattle in the provinces of Liége and East Flanders.—"Consular Reports," June.

Yellow Fever.—Since our last week's record, which closed October 5, yellow fever has slowly but surely been gaining ground. The record is as follows: October 6.—New Orleans 5 deaths, 46 new cases, 2 of the latter being in Algiers, making the total number of cases in Algiers 7; Mobile 4 new cases, Edwards 16 new cases. Nitta Youma 1 new case. October 7.—New Orleans 37 new cases, 2 deaths; Clinton, Miss., 1 new case, Biloxi 10 new cases, Edwards 10 new cases, Mobile 4 new cases, Henderson's Point, Miss., 3 cases. October 8.—New Orleans 47 new cases, 5 deaths; Mobile 6 new cases, Edwards 13 new cases, 4 deaths. On this date a "suspicious" case at Aleo, Ala., was declared genuine yellow fever. October 9.—New Orleans 6 deaths, 35 new cases; Biloxi 15 new cases, Edwards 17 new cases, 1 death; Mobile 3 deaths, 6 new cases. On this date 2 cases were reported at Magazine Point. October 10.—New Orleans 5 deaths, 37 new cases; Mobile 7 new cases, 4 deaths; Edwards 9 new cases, 1 death. On this date Dr. Guiteras declared 4 of the "suspicious" cases at Galveston genuine yellow fever. October 11.—New Orleans 39 new cases, 4 deaths, bringing the total cases in that city to 616, with 65 deaths and 257 total recoveries. Mobile 5 new cases with no deaths, bringing the total cases in that city to 126, with 20 deaths and 67 total recoveries. On this date Bluefields, Nicaragua, announced a nine-day quarantine against Mobile. At Galveston 2 more "suspicious" cases were reported. Many physicians, however, refuse to believe that yellow fever exists in Galveston, although Dr. Guiteras' diagnosis has been confirmed by Drs. Randall and West. As we go to press dispatches of the 12th announce 34 new cases at New Orleans, with 2 deaths; 3 new cases at Mobile. Galveston reports the eleven cases there as convalescing.

Decline of Mortality in Prussia.—Dr. W. Kruse, in *Zeitschrift für Hygiene und In. Krankh.*, has shown for Northern Germany the remarkable decline in the mortality from enteric fever and diarrhea, from smallpox and in the deaths after surgical operations in hospitals (doubtless influenced by antiseptic methods and by new and sanitary buildings), which has been observed in Prussia, and in Germany generally, since the sanitary awakening of twenty years ago. In the successive quinquennia, from 1875 to 1894, the death rates per 10,000 living from enteric fever were 6.17, 4.99, 2.78 and 1.86, and those from diarrhea, 1.63, 1.59, 0.45 and 0.3. Scarlatinal mortality has also declined, the mean mortality from 1875 to 1886 having been between 5 and 6, and from 1887 to 1894 2 and 3 per 10,000. In the periods 1877-79 and 1889-91, the percentage of deaths after operations on bones and joints were respectively 1.4 and

2.7 and for strangulated hernia 21 and 15. The percentage mortality from erysipelas has decreased from 18 to 11.7, and that from consumption from 52 to 36 per 10,000. The death rate from smallpox is full of instruction, showing a very moderate rate during the long period of single vaccination with only a small amount of infection, a period of excessive mortality when a severe infection was introduced by the French prisoners of war into a population only partially protected, and with the primary vaccination generally deferred to the second year, often, indeed, till school age; and lastly, the period of compulsory vaccination and revaccination, the former still, fortunately, not being required till the second year of life, the latter enforced in the fourteenth, there being no means of evading this or the further revaccination of all men passing through the army. The cholera rates are also highly ineteresting. With the exception of the one great outburst at Hamburg, Germany, though from her central position in Europe and her proximity to Russia, for more exposed than this country, has for the same period escaped almost entirely the epidemics that raged in France, Holland and Italy, as well as in Russia and on the Danube.

Death Rates in Brooklyn Reduced by the Use of Pasteurized Milk.—Dr. George E. West, Secretary of the Department of Health of Brooklyn, at the request of the Hon. Nathan Straus of New York City has, under date of September 20, prepared a statement as to the lowered mortality in thirty-eight weeks in children under two years of age in recent years. Dr. West says: "In reply to your request for statistics demonstrating the utility of Pasteurized milk for the purpose of diminishing deaths from diarrheal diseases, I take pleasure in supplying you with the following table, which, it seems to me, is quite eloquent:

Year.	Population.	Deaths.	Rate per 100,000.
1890	854,000	1,331	156
1891	890,000	1,320	148
1892	928,000	1,512	163
1893	973,000	1,492	153
1894	1,045,000	1,382	132
1895	1,100,000	1,507	137
1896	1,125,000	1,338	119
1897	1,160,000	1,170	101

"As the use of Pasteurized milk is confined principally to infants under two years of age, I have used the number of deaths from diarrheal diseases of those infants as a basis of comparison. Further, as only thirty-eight weeks of the present year have expired, I have confined myself for purpose of comparison to the first thirty-eight weeks of each of the other years, which period practically covers the season during which diarrheal diseases occur in large numbers. The last column of my table is obtained by dividing the number of deaths from diarrheal diseases of children under 2 years, as shown in the third column, by the estimated population of the city for the corresponding year, which I consider the fairest basis of comparison possible. The experiment of using Pasteurized milk was begun in this city about the middle of the summer of 1896, and was followed up during the present summer more vigorously and commenced at an earlier date." The New York City Board of Health has, it is said, been antagonistic to Mr. Straus' work, and have endeavored to refer the improved death-rate in New York City to the system of cleaning streets that is peculiar to that city, namely, the "white wings" system. Now this system has not been operated in Brooklyn, so that the explanation that may be desired to be made to that Board does not hold good on the opposite side of the East River.

BOOK NOTICES.

Transactions of the American Climatological Association for the year 1897. Vol. XIII. Cloth, 250 pages. Philadelphia: 1897.

The book is well bound, printed on good paper and shows excellent workmanship throughout. Besides lists of officers and members, and minutes there are twenty-two papers, a series invaluable to the physician or student of the climatic conditions and their relation to the various diseases known to the practitioner. The discussion follows many of the papers.

Proceedings of the Nineteenth Annual Meeting of the Missouri Pharmaceutical Association, held at Meramec Highlands, June 8–12, 1897. Paper. 128 pages. St. Louis: Nixon Jones Printing Co. 1897.

Among reports, etc., the following papers of interest to physicians are noted: "Acids"; "Benzoinated Lard"; "Calcium Hypophosphate"; "Pharmaceutic Chips"; "Glycerin"; "A Pleasant Laxative"; "Metric System in Prescriptions"; "Powdered Opium"; "Quinin Sulphate," and "A So-called Tasteless Quinin," the latter being an exposé of Flora-China, by G. H. Chas. Klie, Ph.G., M.D.

Transactions of the Rhode Island Medical Society, Vol. V, Part III, 1896. Paper. Providence: 1897.

This volume contains the proceedings of the annual meeting, obituary notices, lists of Fellows, etc., and the following papers: "Anesthesia"; "Compulsory Vaccination"; "Report of a Case of Tubercular Peritonitis"; "Case of Retention of Urine from Enlarged Prostate"; "Only Nervousness"; "Posture in Disease"; "Two Cases of Gastric Ulcer"; "Remarks on a Case of Syphiloderma Gummatosum"; "A Case of Myxedema"; "Remarks on Myxedema."

The Ophthalmoscope. A Manual for Students. By GUSTAVUS HARTRIDGE, F.R.C.S. Third Edition. Philadelphia: Blakiston, Son & Co. 1897.

This little book of 150 small octavo pages is equally useful to the student as well as to instructors of ophthalmology; to the former, because the subject is presented in so simple language and rendered so clear by numerous illustrations that the student can easily understand it. And to the instructor it may serve as a good example of teaching ophthalmology successfully to medical students.

Missouri Botanical Garden; Eighth Annual Report. St. Louis, Mo.: Published by the Board of Trustees. 1897.

This volume contains scientific papers on the mosses of the Azores by J. Cardot; on some mosses collected in Madeira by William Trelease in June, 1896. Botanic observations on the Azores by William Trelease. The volume also contains a list of books and papers published by the Garden or its employes for the last seven years and the report of the officers of the board. The report of Director Trelease is extremely interesting and the illustrations are excellent. All botanists and persons engaged in the study of botany will be interested in the volume.

Transactions of the State Medical Society of Wisconsin for the year 1897. Vol. XXXI. Cloth, pp. 667. Madison: 1897.

The report includes the Constitution and By Laws, lists of members, officers and committees, proceedings of the fifty-first annual meeting, reports of the various officers and an obituary list. The papers are arranged according to their section, there being ten treating of surgical topics, eight on laryngology and rhinology, twelve on practice of medicine, seven on gynecology, eight on obstetrics, six on state medicine and hygiene, seven on materia medica and therapeutics and three each on ophthalmology, otology and pediatrics. The work is on good paper and in clear type, a valuable addition to literature of this field.

The Normal and Pathological Circulation in the Central Nervous System. Original studies by WILLIAM BROWNING, PH.B., M.D. Pages 171, with two plates. Price $1.50 Philadelphia: J. B. Lippincott Company. 1897.

This work consists of certain special articles on the intercranial circulation. It is not intended as a comprehensive treatise on the subject, but it covers considerable original work. There is much to commend in the book, especially the original experimentation of the pathologists, and the work is a rebuke to howling antivivisectionists for the practical experiments made on dogs and monkeys. Most of the chapters in the work consist of papers read by the author before various societies, extended in some cases and in all revised.

It is a work of interest to all physiologists and pathologists, and practitioners desiring to increase their knowledge on anatomy and physiology of the central circulatory system.

Convergent Strabismus and Its Treatment. An Essay by Edwin Holthouse, M.A., F.R.C.S., Surgeon to the Western Ophthalmic Hospital. London: J. and A. Churchill. 1897.

This essay is the result of a careful study of 144 cases of convergent strabismus. As the majority of these cases were under observation during a period varying from nineteen months to four years, the author was in the position of collecting very precise information of the ultimate results of his treatment, and of summing up his experience in certain general principles which should be followed in dealing with convergent strabismus.

He strongly insists upon the early use of correcting glasses and most emphatically warns against early operations. "At the outset," he says, "we hold it to be a matter of primary importance that in every case in which their regular use can be depended on, fully correcting lenses should be prescribed as soon as possible after squint has made its appearance." During the first three years the prescription of spectacles is, for obvious reasons, out of question; if the squint is slight and stationary, it is better not to interfere at all until spectacles can be worn, but when the squint is progressive atropin should be used to check its progress. Anything in the way of operations, however, he regards as positively inadmissible in children of this tender age. "Whoever has seen the disastrous results which may follow a tenotomy performed at this early age can have no hesitation in pronouncing any such procedure unjustifiable." The spectacle treatment brought about a permanent reduction of the convergence in more than 60 per cent., diminished the squint as long as the glasses were used in about 30 per cent., and only in 8 per cent. no improvement whatever was noted. When glasses have accomplished all they can do or when they have no effect upon the convergence, operative procedures are in order. These are then discussed in details which are very interesting to the ophthalmic surgeons, to whom this book can not be too highly recommended for its wealth of valuable information.

The Origin of Disease, especially of disease resulting from intrinsic as opposed to extrinsic causes. With chapters on Diagnosis, Prognosis and Treatment. By Arthur V. Meigs, M.D., Physician of the Pennsylvania Hospital. With One Hundred and Thirty-seven Original Illustrations. Philadelphia: J. B. Lippincott Company; London: 6 Henrietta St., Covent Garden, 1897.

The author as he says, impressed by the separation of clinical medicine from pathology has endeavored to bring them nearer together. It is a pleasure to examine a book made up as this is of the result of original work. The illustrations, which are numerous and well executed, are drawings from actual specimens to the author's work in the pathologic department in the Pennsylvania Hospital and have never before been published. There is certainly no book published in this country that will compare with this for precision or accuracy and wealth of illustrations. There is no padding in the book, no attempt at fine writing, but plain, straight-forward statements of the conditions found in the specimens examined. The author makes a plea for the systematic examinations of postmortem cases that die in the hospital, and we fully concur in the author's conviction "that many diseases usually considered as confined to one organ are seldom so confined, for at the postmortem it has been found that there are lesions of other organs as definite as those of the part considered to be the seat of origin. At the same time many of the lesions are of such nature as to render it certain that they existed before the onset of the fatal attack." The author considers that practically all diseases may be divided into two general classes, those of extrinsic and of intrinsic origin. The work is creditable alike to the author and the publisher.

NECROLOGY.

Luke Robinson, M.D., suddenly of heart disease, on a Southern Pacific train near Lathrop, in the San Joaquin Valley, October 10. He was a member of the Royal College of Physicians and Surgeons, and an ex-president of the State Medical Society of California, besides being connected with the State University and other public institutions.

John K. Eshleman, M.D., Jefferson, 1835, died in his 88th year in Lancaster, Pa., October 7. He was well known as a contributor to the magazines and newspapers on horticultural subjects.

Peter Y. Frye, M.D., Dartmouth, 1846, born in Candia, N. H., died at his home in Oyster Bay, L. I., New York, October 9, aged 80 years. He was at one time president of the Queens County Medical Society and also officially connected with the Oyster Bay Bank.

James J. Moore, M.D., Syracuse, N. Y., October 3. Dr. Moore was born Oct. 21, 1861, at Stittsville. He received his early education in the West Winfield academy, from which he was graduated in 1875. He entered the medical department of the University of New York and was graduated in 1882. In politics Dr. Moore was a Republican and took considerable interest in municipal affairs. He served four years as school commissioner, representing the Sixth and Eighteenth wards, 1892-5 inclusive. He was a charter member of the Academy of Medicine and a prominent member of the Onondaga County society.

Dr. Welcker, who was for a great number of years professor of anatomy in the University of Halle, died in August at Winterstein. He was born in 1822 in Giessen, and studied in that university and in Bonn, taking his degree in 1851. It was not long before he began to give evidence of his ability by writing important papers on physical and physiologic subjects, many of which were connected with optics. Subsequently he made some valuable researches on the blood, the anatomy of the ventricles of the brain, and the development of the skeleton. He did not entirely confine himself to medical science, for he found time to publish a work on German poetic dialects. His first chair was in Giessen, where he taught anatomy both as *privat docent* and then as professor. In 1859 he accepted an invitation to teach anatomy in Halle, from which chair he only retired in 1894. In 1876 he was appointed to succeed Professor Volckmann as director of the Halle Anatomical Institute.——Dr. R. Berlin, professor of ophthalmology in the University of Rostock.——Dr. Surmay, corresponding member of the Paris Academy of Medicine.—*Lancet*, September 25.

Joseph M. Lovell, M.D., the first medical martyr to the yellow fever in New Orleans, September 22. He attended one of the earliest cases and was stricken soon after. He was chief of clinic to one of the Polyclinic professors.

John H. Bemiss, M.D., died September 2, aged 41 years and not of yellow fever (*Vide* Journal September 25, p. 660); our data were taken from the press dispatches which seemed to be verified by their number.

Scott Helm, M.D., Phœnix, Ari., October 8, aged 35 years. He was graduated from Rush Medical College in 1883, eventually locating in Phœnix, where he was Surgeon-General of the Territory for seven years. Dr. Helm died from injuries received by being thrown from his horse.

Ira L. Moore, M.D., Jefferson, 1851, died at the Parker House, Boston, October 2, aged 73 years. He was born in Candia, N. H., and was graduated from Amherst College at the head of a class of 227, carrying off the honors in all branches of study. After his graduation he formed a copartnership in Lowell, Mass., with Dr. Graves, a former instructor. In 1856 he was elected to the State Legislature from Lowell. In 1858 he ran for the State Senate against General B. F. Butler, and was defeated by a small majority. In 1860 he went to Boston, and in 1861 was elected to the School Committee for three years. He was elected to the legislature, where he served in the years 1865, 1866, 1870 and 1871. To Dr. Moore was given the credit of having the Back Bay district of Boston changed from a tide marsh to a beautiful residence district, which has added $100 000,000 to the assessed valuation of the city.

Edward Grether, M.D., of Brooklyn, September 22, aged 57 years. He was a native of Germany and a graduate from the University of Würzburg in 1869. Soon after graduating he emigrated to this country and about twenty years ago took up his permanent residence in Brooklyn. He was a practitioner greatly respected among his fellow-countymen living in his section of that city. His death was due to myocarditis complicated with hydrothorax.

Henry E. Branin, M.D., Jefferson, Philadelphia, 1858, died suddenly from paralysis October 6, at the Camden County Insane Asylum, Blackwood, N. J. With this institution he was connected for about twenty years. Until their separation five years ago the almshouse and asylum were one. He remained with the asylum.

Samuel McNutt Ross, M.D., Jefferson, 1850, died September 13 at Altoona, Pa., where he had been a practitioner since 1875. He was a member of the American Medical Association, State and Blair County (Pa.) Medical Societies, once a Censor of the Western Reserve University Medical Department, Cleveland, Ohio, and also a consulting physician of the Altoona Hospital. His death at the age of 73 years was in consequence of injuries from being knocked down by a wagon.

Robert R. Ball, M.D., Assistant Surgeon U. S. A., commissioned November, 1896, died in Washington, D. C., October 4, after a week's illness. He was recently stationed at Fort Adams, Newport, R. I.

Charles T. Roy, M.D., according to a London dispatch of October 5, is dead. He was born in 1854, was a surgeon in the Turkish army during the Servian War, professor, superintendent of the Brown Institution, professor of pathology at the University of Cambridge since 1884, and a contributor to several medical journals.

T. F. Fulton, M.D., Beatrice, Neb., at Union City, Pa., September 29, aged 74 years.——J. W. Norris, M.D., Palmyra, Mo., October 4.——E. v. Hofmann, aged 60 years; Professor Legal Medicine, Vienna; Director Medico-Legal Institute, etc.——J. T. de Sousa Martens, Professor General Pathology, Lisbon.——Joseph J. Sweet, Jr., M.D., Albany, N. Y., 1894, died in the City Hospital, Albany, October 3, aged 29 years.

MISCELLANY.

Change in Name.—Dr. H. Davison Scharschild of New York, by virtue of granted permission of the supreme court has taken the name Dr. H. Davison Saril.

Needle in Epiplocele.—Tuffier confirmed his diagnosis with a radiograph, which showed the large needle distinctly.—*Presse Méd.*, August 12.

Journal du XII Congres International de Medecine.—These daily bulletins, Nos. 2 to 8, have been received through the courtesy of Dr. B. F. Whitmore, with the firm of Parke, Davis & Co.

American Medical Books in England.—The only medical lexicon that receives mention in the students' number of the London *Lancet*, August 21, is Dr. G. M. Gould's large work. Among other American books that are recommended to the English student of medicine are the works of Pepper, H. C. Wood, Osler and Da Costa; also those of Senn, W. W. Keen and Lusk. Of the late Dr. Lusk's book on midwifery the *Lancet* says that it is without doubt in many ways the best text-book in the English language on the subject.

Ninety Centigrams of Calomel in Six Days were taken by mistake, by a patient being treated for malignant syphilis in Turin. The general reaction was what might be expected from such an amount, but after recovery from this the syphilis had disappeared and there have not been the slightest manifestations of it since.—*Gaz. d. Osp. e. d. Clin.*, August 15.

Roentgen Ray in the Study of Anatomy.—Diakonoff usually injects the vessels with mercury, but as this is heavy and tends to alter the shape, he has found the following mixture preferable for certain cases: Plaster of Paris, cinnabar and minium āā 20 parts; flour 10 parts: water to make a liquid paste.—*Presse Med.*, August 12.

The Library of Sir Morell Mackenzie has been advertised for sale in a London auction room. Besides a large number of general works there are many recognized authorities on his specialties. Among his own contributions to medical literature there were many copies of his "Growths in the Larynx" and "The Laryngoscope," both published in 1871, also of "Leprosy of the Air Passages."

International Congress for the Study of Tuberculosis will be held at Paris next July, with Nocard, president, and G. Masson, treasurer, 120 Boulevard St. Germain. *Themata* announced: 1. "Sanitaria in the prevention and treatment of tuberculosis." 2. "Serum and antitoxin treatment of tuberculosis." 3. "Value of the Roentgen ray in recognition and treatment of tuberculosis." 4. "Prophylaxis of tuberculosis in animals." Membership fee, 20 francs.

Rule Made That Medical Schools Must Teach in English.—The quarterly meeting of the State Board of Health was held at the Great Northern Hotel, Chicago, October 5. A resolution was adopted that after May, 1901, no school of medicine or midwifery would be recognized unless its instruction was given in the English language. A number of schools of midwifery in Chicago will be affected. After May 1, 1898, no candidate for license to practice medicine in the State will be examined unless he gives documentary evidence of a preliminary or basis education equivalent to that of a high school course.

Two-fold Effect of Alcohol on the Muscles.—H. Frey's communication on this subject is based on numerous and comprehensive experiments and tests, principally with Mosso's ergograph. He found that alcohol stimulated fatigued muscles to an increased amount of work, but produced the opposite effect on non-fatigued muscles. It also deadens the sensation of fatigue. He explains its two-fold action as: 1, a paralyzing action (central) deadening the sensation of fatigue, and (peripheral) diminishing the work accomplished by the muscles; 2, a nutritive effect, supplying new fuel to fatigued muscles.—*Deutsche Med. Woch.*, August 19.

Extensive Drainage.—The extent to which Ewald carries drainage in all kinds of hydrops and accumulations of fluid with edema, is shown by a recent case he describes in the *Berl. Klin. Woch.*, No. 25. A man 33 years old presented uremic manifestations and ascites in connection with inflammation of the kidneys. He was helped along past the critical period by punctures whenever the fluid accumulated enough to annoy him, the case terminating in recovery after 161 liters of fluid had been withdrawn in the course of six months. The pleural cavity was punctured five times, the abdomen forty-five times and the legs on one or both sides as required.

Radical Cure of Inguinal Hernia.—Nélaton has been practicing a method of radical cure with orchidopexy, which he describes in the *Presse Méd.* of July 31, recommending it for all cases in which the tissues are thin and weak, with consequent difficulty in securing solidity with the usual Bassini operation. The innovation is the cutting out of a round disc the size of a centime in the body of the pubis, 8 millimeters below the edge, with Collins' punch forceps. The thin strip of bone left above it is then sawed through and raised on its hinge of periosteum, to allow the cord to be placed in the hole left by the removal of the disc. The bridge of bone is then replaced and sutured, and the abdominal wall restored in two layers. He concludes by expressing his conviction that time will confirm the effectiveness of this transpubian passage of the cord, which retains its mobility; the testicles also cease to rise up in ectopic cases, while the course traveled by the cord is shortened at least a centimeter.

Blasucci's Hypogastric Syphon for drainage of the bladder after epicystotomy has been used for some time in the Galozzi clinic with brilliant results; the wound entirely healed in twelve days. It prevents the passage of any urine through the abdomino cystic wound, and can also be used for lavages when desired. It consists of a rubber tube in two branches, connected by a T-shaped glass tube. The short branch has four large holes at the farther end, with a bulb, blown up through a smaller tube adherent to the principal tube but not communicating with it. The long branch reaches below the bed, the end terminating in a glass ampulla, with a hole in the side, hanging in an antiseptic solution.—*Gaz. degli Osp. e delle Clin.* August 15.

A Juvenile Mistake.—One of our readers sends us the following: A bright little eight-year old boy was sent to the family physician's house one evening, he being a near neighbor, to have diagnosed several eruptive areas of "vesicles clustered on erythematous bases arranged in the course of the terminal twigs of the intercostal nerves and forming a semigirdle round the trunk" (Fox); he was informed that he had "shingles" and that he was to tell this to his parents. When he arrived home his mother asked him: "What did the doctor say was the matter with you?" When the little fellow promptly replied: "The doctor said I had the *slats*."

Dr. Bates is Surgeon-General.—Newton L. Bates, M.D., has been appointed by the President as Surgeon-General of the Navy and Chief of the bureau of medicine and surgery of the Navy. He succeeds Surgeon-General J. Rufus Tryon. Dr. Bates is a native of New York and now in his 59th year. He entered the Navy as an assistant surgeon in July, 1861, and saw considerable active service on blockading squadrons during the War for the Union. He reached the rank of surgeon in September, 1865, that of medical inspector in January, 1881, and medical director in September, 1888. After the war Dr. Bates saw service on every quarter of the globe, his last cruise having been on the flagship Pensacola in 1888. Since then he has been on duty successively at the Mare Island (Cal.) Naval Hospital as a member of the Medical Examining Board, and at the Naval Museum of Hygiene in Chicago, to which last position he was assigned in May, 1895.

An Application of the Neuron Theory to the electric treatment of hemiplegia was communicated by V. Seletzki recently to the Kiew Medical Association, with which he has been very successful. It is based on the idea that in cerebral lesions, when the focus heals, the compressed portion of the pyramidal tracts will resume their normal condition and functions if the neurons have been kept from atrophy and the muscles from losing their habit of functional activity from lack of use in the mean while. He attains this by electric treatment, which exercises the neurons (galvanization) and the muscles (faradization). He first galvanizes the head by placing the cathode on the hemisphere involved in the lesion, with the anode at the back of the neck. Then the hand is placed in salted water with the anode; the cathode at the back of the neck, after which the foot is galvanized in the same manner. The currents must be very weak and of brief duration. Muscular contractions are induced at the same time with an interrupter applied to the muscle, while the patient assists, by raising the hand, for example, when the deltoid is being treated. With this treatment he has restored motion to groups of muscles that had been paralyzed from seven to fourteen months, which ordinary electrization could never have accomplished. In one case of eruptive trophoneurosis of five years' standing, in which the pruritus rendered sleep often impossible, improvement was observed after the first séance, also in three cases of polyneuritis.—*Presse Méd.*, July 24.

Personal.—Dr. John S. Billings, now of New York City, is engrossed with the congenial work of cataloguing the literary treasures of the public library, the consolidated successor of the Astor, Lenox and Tilden collections. He has improved if not perfected the card system. When his new system of classification is finished it is his intention, as the responsible librarian, to have a shelf-list made by which the books may be checked off from time to time. In making up the groups already practically complete, some of the books mentioned in the earlier catalogues have not been found. Dr. Billings does not say that they have been stolen, but thinks it possible that they have been mislaid or shoved back out of sight. With such a list it will be easy to determine whether or not any books have disappeared.——Dr. Newborn, U. S. M.-H.S., who for the last seven years has been detailed as medical examiner of immigrants at the port of New York, has resigned with the intention of studying in Europe.

The "Dover Cliff" Case of Prolonged Unconsciousness.—Considerable attention has been given in England to a peculiar case, known as the "Dover Cliff Mystery." On August 5 a young girl aged 17 years was found unconscious and bruised, on the beach near St. Margaret's at the foot of a cliff 200 feet high, and was removed to the Dover Hospital. The character of her injuries (a severe bruise on the right side of the forehead and slighter contusions on the occiput and left ankle) makes it seem most improbable that she had fallen over the cliff, as was at first supposed, and it has been suggested that she was sunstruck while walking on the beach and received the bruises in falling to the ground. The possibility of the case being one of typhoid fever arises when it is remembered that long periods of unconsciousness, lasting more than four weeks, have been known to occur in this disease. The temperature curve, also, is not unlike that of typhoid. The principal treatment has been the use of the cold pack whenever the temperature rose above 102 F. Bromid of ammonium and iodid of potassium were given internally, with a diet consisting of milk and beef tea. The systematic use of the ice-pack and close attention to nutrition has kept the girl alive, but her unconsciousness persists.—*Medical News*, October 2.

Acute Ascending Paralysis as a Complication of Pasteur's Treatment; Recovery.—Rendu reports a case in which acute ascending paralysis supervened on Pasteur's treatment. The patient pricked his finger while assisting at a necropsy on a man who had died of hydrophobia. As a prophylactic measure he was treated at the Pasteur Institute and received sixteen injections between March 22 and April 1. On the latter date he felt cold and the following day was ill, with a feeling of heaviness in the legs so that he could hardly walk. There was also some pain in the loins like lumbago. The temperature was only slightly raised and there was some general hyperesthesia. On April 3 there was marked paresis of the lower limbs, with muscular pains and almost complete anesthesia of abdomen, lumbar region and lower limbs; there was also paralysis of the bladder. On April 4 paraplegia was almost absolute and involuntary defecation occurred about this time. There was no difficulty in respiration or in swallowing. On April 6 some weakness of the upper limbs came on and the heart became rapid. During this time the injections had been continued, as it was considered important to complete the immunization. On April 7 improvement began; the arms were no longer weak, and there was some return of power and sensation in the legs. Progress was rapid and within three weeks the patient was quite convalescent. That the case was one of paralytic rabies seems unlikely, as the incubation was too short and the clinical course unlike it. It seems more likely that an acute ascending myelitis was caused by some toxin in the emulsion of spinal cord which was injected, and that though usually harmless, the toxin proved virulent in this case owing to the receptive soil produced by the unhealthy surroundings to which a postmortem room attendant is continually exposed.—*British Medical Journal.*

Hypnotism Before the Court.—A witness was called on behalf of the defendant in the murder case of People v. Ebanks, and an offer was made to prove by him that he was an expert hypnotist, that he had hypnotized the defendant and that when hypnotized the defendant had made a statement to him in regard to his knowledge of the affair, from which statement the witness was ready to testify that the defendant was not guilty and that the defendant denied his guilt while in that condition. The trial judge sustained an objection to the testimony. He said: "The law of the United States does not recognize hypnotism. It would be an illegal defense and I can not admit it." Mr. Commissioner Searls, who prepared the opinion of the supreme court of California, wherein it, Aug. 23, 1897, affirmed the judgment of conviction of murder in the first degree, said: "We shall not stop to argue the point, and only add the court was right." Commissioners Belcher and Chipman concurred. Mr. Justice McFarland said: "I concur in the judgment and in the opinion of Mr. Commissioner Searls, but what is said in the opinion on the subject of hypnotism must be taken as applicable to the testimony offered on that subject in this case, which was clearly inadmissible, and not as covering the whole subject. It will not be necessary to determine whether or not testimony tending to show that a defendant committed the act charged while in a hypnotic condition is admissible until a case involving that precise question shall be presented." In this utterance, Justices Henshaw and Van Fleet concurred. By this decision the trial of cases by hypnotists rather than by jurors is eliminated, for one State at least. But the suggestions made in the supplemental opinion open wide the door for further legal discussion of the question of the importance to be attached to allegations of crime being committed under hypnotic influence.

Functions of the Thyroid Gland Finally Established.—The second communication from Prof. E. v. Cyon on the "Physiologic Connection Between the Nerves of the Heart and the Thyroid Gland," appears in the *Cbl. f. Phys.* of August 21 (*vide* Journal, September 4, p. 504). He summarizes the result of his research as follows: 1. The function of the thyroid gland consists in the formation of a substance, iodothyrin, the chief purpose of which is to stimulate the regulating nerve mechanism of the heart to increased activity. At the same time by this transformation into an organic combination of the iodin salts finding their way into the blood, the thyroid gland succeeds in freeing the organism from substances that affect this mechanism very injuriously. 2. This function of the thyroid gland is controlled by the heart through the intermediation of the nerves previously mentioned. In this way the heart itself superintends the production of the iodothyrin necessary to its normal activity. 3. The thyroid gland owing to its location near the entrance of the carotids into the cranial cavity, and its capacity for receiving large quantities of blood into its vessels and passing it along, forms a kind of safety contrivance to prevent the brain from becoming over-gorged with blood at any sudden increase in the work accomplished by the heart or from constriction in the peripheral vascular route. In such cases the thyroid gland may act the part of a safety flood-gate, offering very slight resistance. 4. This second function of the thyroid gland is likewise under the direct control of the heart, which, by stimulating the vasodilating fibers of the thyroid gland, wards off the threatening danger from the brain in two ways: 1, by opening the sluices to divert the surplus stream of blood, and 2, by increasing the amount of iodothyrin produced.

Washington.

Health of the District.—The report of Health Officer Woodward for the week ended October 2, shows the number of deaths reported to have been 92, of which 54 were white and 38 colored. There were 3 fatal cases of typhoid fever and 4 of diphtheria. In his estimate for the expenses in his department for the current year he asks the following: Smallpox hospital, $5,000; disinfecting service, $5,000; abatement of nuisances, $1,000; gratuitous vaccination for the indigent, $2,000; enforcing the act regulating contagious diseases, $25,000; incinerating combustible waste, $15,000; establishment and maintenance of bacteriologic laboratory, $5,000; crematory for potter's field, $25,000; medical inspection of public schools, $10,000; one physician who shall act as clerk and deputy health officer, $1,800; five additional sanitary and food inspectors at $1,200 each; one veterinary surgeon, $900; $200 per annum increase is asked for the chief clerk and each of the physicians to the poor; $520 increase for the purchase of drugs.

Providence Hospital Training School.—At the commencement exercises of the Providence Hospital Training School, recently held, Dr. John W. Bayne presented the diplomas to five graduates from the school.

Medical Association.—At the regular stated meeting of the Medical Association of the District, held on the 5th inst., the following were elected to membership: E. B. Behrend, A. W. Boswell, J. R. Church, Henry Darling, L. H. French, R. H. Graham, M. Griffith, A. G. Grenwell, A. Barnes Hooe, L. Johnson, G. W. Johnston, A. L. Lawrence, M. D. Magee, M. E. Miller, M. G. Motter, W. C. Murphy, W. S. Newell and Jesse Ramsburgh. The Association, in keeping with the promise of the Washington delegation to the American Medical Association, voted $390 to be paid to the Rush Monument Fund. Dr. Samuel C. Busey, who was the official delegate of the Association to the British Medical Association at Montreal, addressed the Association, giving a very interesting account of that meeting.

Washington Obstetrical and Gynecological Society.—The 267th meeting of the society was held on the 1st instant. The president, Dr. George Byrd Harrison, delivered a valuable and interesting address on general medicine. The annual banquet of the society has been arranged for by the special committee in charge, to take place on the 15th instant.

Medical Society.—At the meeting of the Medical Society held on the 6th instant, the following were elected to membership: Louis J. Battle, Joseph Lacy Brashaw, Franz A. R. Jung and F. A. Mazzie. Dr. McArdle read the essay for October, entitled "Tubercular affections of the female genitalia." His essay was highly scientific and instructive and was discussed by Drs. Smith, Stone, Bovee, G. W. Johnston, Forward, U. S. A., and H. L. E. Johnson.

The National Medical Review.—The former editor of the *National Medical Review*, Dr. Chas. H. Stowell, has removed from Washington to practice in Boston. The journal has passed into the hands of Drs. T. E. McArdle and George Woodruff Johnston, by whom it will be conducted in the future.

Detroit.

At the regular meeting of the Wayne County Medical society held on the evening of September 30, Dr. L. E. Maire read a paper on "An Improved Bandage for Cataract Operations." The bandage presented is made in the following way: A roll of starched crinoline bandage about three inches wide is thoroughly wet in warm water for the purpose of softening it.

It is then wound in the usual manner of applying a bandage over both eyes, around the head, the toilet of the operated eye having been made and it as well as its fellow covered carefully with a layer of absorbent cotton, which extends on both sides well around and over the patient's ears. After three or four turns have been taken, a piece of cardboard of circular shape, and from two to three inches in diameter, is completely moistened in water and placed over the operated eye. The bandaging is then completed, covering the pasteboard with a few more layers of the moistened crinoline. When the bandage becomes dry it is hard and firm. It is molded perfectly to the form of the face, and will prevent any ordinary injury to the operated eye because of the protecting covering of both the stiff crinoline and pasteboard which covers it. The bandage may be removed by cutting through it at the back of the head. Eyelets can be made in each side of the divided ends and the bandage replaced and fastened on securely by lacing; when the sound eye may be released, an opening may be cut out of the bandage immediately in front of it. The author claims for the bandage that it is light, that it is easily and readily applied, cheap and practical, and that it affords complete protection.

THE DETROIT MEDICAL AND LIBRARY ASSOCIATION at its annual meeting Monday, October 4, elected the following officers for the ensuing year: Dr. Andrew P. Biddle, president; P. C. McEwen, secretary; Edward G. Knill, vice-president; I. W. Gillman, treasurer.

Hospitals.

BY THE WILL of the late Henry Keep of Chicago, St. Luke's Hospital receives $5,000.——St. Alexander's, a new hospital, was dedicated at New Ulm, Minn., September 22.

THE NASSAU HOSPITAL of Queen's County, N. Y., held a fair at the Mineola grounds on October 7.

PATHOLOGIC INSTRUCTION AT THE LOUISVILLE CITY HOSPITAL.—The *American Practitioner and News*, September 4, refers to the following important improvements that have been instituted at the above named hospital: "We are pleased to learn that a capacious amphitheater, perfectly lighted by skylight and electricity, has been added to the equipment of the Louisville City Hospital for the purpose of enabling the students of the medical schools of the city to witness autopsies and pathologic demonstrations upon certain cadavers which will be set apart for this purpose. Autopsies held at other than regular hours will be advertised by notices posted on the bulletin-boards of each school. A museum for the preservation of the specimens resulting from this work will be provided in the near future. This department is under the care of Dr. Leon Solomon, pathologist to the Louisville City Hospital, and we are glad to learn that the new departure is in the main due to his influence and energy. The opportunity thus afforded our students of medicine for familiarizing themselves with the microscopic features of fresh pathologic lesions is of great value, and thanks are due Dr. Solomon for making it prominent in the teaching facilities of our city."

Societies.

The following meetings were held recently:

Alabama.—Calhoun County Medical Society, October 5.

Illinois.—American Academy of Railway Surgeons, Chicago, October 6-8.

Indiana.—Allen County Medical Society, Fort Wayne, September 29; Tippecanoe County Medical Society, Lafayette, October 4; Upper Maumee Valley Medical Association, Columbia City, September 29.

Iowa.—Clinton County Medical Association, Clinton, October 5; Iowa State Association of Railroad Surgeons, Des Moines, October 13 and 14.

Minnesota.—Winona County Medical Society, Winona, October 5.

Nebraska.—Elkhorn Valley Medical Society, Norfolk, October 5.

New York.—Medical Association of Troy, October 5.

Ohio.—Allen County Medical Society, Lima, October 5; Cuyahoga County Medical Society, Cleveland, October 5; Miami Valley Medical Society, Loveland, October 12; Trumbull County Medical Society, Warren, September 29; Union Medical Society of Northeastern Ohio, Alliance, September 29.

CHANGE OF ADDRESS.

Ball, M. V., from 529 Pine St. to Warren, Pa.
Barber, W. M., from Binghamton to Scio, Ohio.
Birkhofer, W. J., from Primghar to Thor, Iowa.
Boyd, W. J., from Topeka, Kans., to Pavilion, N. Y.
Butler, Thos. L., from 1511 Floyd St. to 1511 Fourth St., Louisville, Ky.
Clausen, J. J., from 1400 Summit to 404 New Ridge Bldg., Kansas City, Mo.
Coon, J. W., from 807 Walnut St. to 838 Booth St., Milwaukee, Wis.
Fanner, J. C., from White Bear Lake to Minneapolis, Minn.
Hatch, W. G., from Chicago to Prairie City, Ill.
Hanna, C. U., from Portsmouth to Pataskala, Ohio.
Hill, R. J., from 620½ Nicollet Av. to Room 2 Syndicate Block, Minneapolis, Minn.
Howard, W. E., from Kasbeer, Ill., to Bellevue Hospital Medical College, New York.
Kenyon, E. L., from 1753 Milwaukee Av. to Room 8, Peoples' Institute Bldg., Chicago.
Langsdale, J. M., from 1212 Tracy to 512 Altman Bldg., Kansas City, Mo.
Penncock, V. R., from Silver Plume to Longmont, Colo.
Pick, Albert, from Hyannis to Brockton, Mass.
Proctor, C. M., from Harvard, Ill., to Helena, Mont.
Pyle, Walter, from 119 S. 17th St. to 1831-33 Chestnut St., Philadelphia.
Walher, W. E., from Pass Christian to Bay St. Louis, Miss.
Warden, A. W., from 130 West 104th St. to 118 W. 82d St., New York.
Weeks, John E., from 151 Madison Av. to 46 E. 57th St., New York.
Weitz, J. A., from Montpelier, Ohio, to 509 3d Av., Detroit, Mich.
Wolfe, A. G., from 755 N. High St. to 35 W. 4th Av., Columbus, Ohio.

LETTERS RECEIVED.

THE PUBLIC SERVICE.

Army Changes. Official List of Changes in the Stations and duties of officers serving in the Medical Department, U. S. Army, from October 2 to 8, 1897.

First Lieut. Thomas J. Kirkpatrick, Jr., Asst. Surgeon (Ft. Douglas, Utah), is granted leave of absence for one month.

Capt. Richard W. Johnson, Asst. Surgeon, ordered to proceed from Ft. Logan, Colo., to Ft. Douglas, Utah, and report for temporary duty.

Capt. James D. Glennan, Asst. Surgeon, is relieved from duty at Ft. Clark, Texas, and ordered to Ft. Myer, Va.

Capt. Norton Strong, Asst. Surgeon, order assigning him to duty at Ft. Myer, Va., is revoked.

Capt. Robert R. Ball, Asst. Surgeon, died Oct. 5, 1897, at Washington, D. C.

Major Paul R. Brown, Surgeon, having been found by an Army retiring board incapacitated for active service by reason of disability incident to the service, is by direction of the President retired from active service this date, Oct. 1, 1897.

First Lieut. Leigh A. Fuller, Asst. Surgeon, is relieved from duty at Ft. Meade, S. Dak., and ordered to Ft. Assiniboine, Mont.

First Lieut. Edward L. Munson, Asst. Surgeon, is relieved from duty at Ft. Assiniboine, Mont., and ordered to Ft. Adams, R. I.

Capt. George McCreery, Asst. Surgeon, is relieved from temporary duty at the Soldiers' Home, Washington, D. C., and ordered to Ft. Myer, Va.

Capt. Edgar A. Mearns, Asst. Surgeon, is relieved from duty at Ft. Myer, Va., and ordered to Ft. Clark, Texas.

PROMOTIONS.

Capt. Junius L. Powell, Asst. Surgeon, to be Surgeon with the rank of Major, Oct. 1, 1897, vice Brown, retired.

RETIREMENT.

Major Paul R. Brown, Surgeon, Oct. 1, 1897, for disability incident to the service.

The Journal of the
American Medical Association

VOL. XXIX. CHICAGO, ILL., OCTOBER 23, 1897. No. 17.

ADDRESS.

MENTAL EVOLUTION IN MAN.

An address delivered at the opening of the Section of Psychology, at the Sixty-fifth Annual Meeting of the British Medical Association, Montreal, Aug. 31 to Sept. 4, 1897.

BY R. M. BUCKE, M.D.

MEDICAL SUPERINTENDENT OF THE INSANE ASYLUM, LONDON, ONTARIO, CANADA, PRESIDENT OF THE SECTION.

[Abstract from advance sheets of the British Medical Journal.]

About sixty years ago, in the time of the Millerite excitement, a man who believed that the world was about to end expressed his fears to Emerson, who replied that it was really a matter of little consequence, "for," said he, "we can do very well without it." There are wise men who teach that each man creates the world he lives in, and as he gives it its substance so also does he give it its quality, insomuch that it is good or bad as he is good or bad. Be this as it may, it is certain that each one of us is of more consequence to himself than is all the outside world. Not only so, but the essential part of each man is what we call his mind, in comparison to which the body is an insignificant factor.

The study of psychology.—Psychology ought to be the most interesting of all the sciences, and as a matter of fact it undoubtedly is, though it has been greatly discredited by the imperfection of the method by which it has until very lately been studied. That imperfection is so great that it would hardly be an exaggeration to assert that nearly all the study and thought expended upon it down to the beginning of our own age has been fruitless and as good as wasted, except inasmuch as it has at last made clear the impassability of the route men have sought to follow, the route, namely, of introspection. For we might as well study the human body alone without reference to that of any other creature and attempt in that way to decipher its genesis, development and meaning as to attempt to comprehend a single human mind without including in our examination not only other human minds in all stages of evolution, but equally all other minds to which our own is related, that is to say, all minds other than human belonging to our kinsfolk, the animals, minds which stand today like mile posts along the almost infinite length of the path which our mind has followed in its upward march across the immensities and eternities from its remote infancy to the present hour; minds which in a thousand faculties represent to us everywhere, in infinite sameness and variety, *replicas* of our own or of parts of our own, showing us, as the poet says, tokens of ourselves which we "negligently dropped as passed that way huge times ago."

Comparative psychology.—As man's bodily life rests upon and grows from that of countless prehuman ancestors; as man includes in his structure the heart of the reptile, the gills of the fish, as well as the forms in outline of innumerable still lower races, so is his so-called human mind rooted in the senses and instincts of all his ancestral species; and not only so, but these senses and instincts still live in him, making up, indeed, far the larger part of his current every-day life; while his higher psychic life is merely the outgrowth and flower of them.

As truly as the plant is an embodiment of inorganic matter vivified by the transmuted forces which in the non-vital world about us we call light and heat, so truly is man's mind the outcome of—the expansion and culmination of—the imperfect sensation of the worm, the rudimentary sight, hearing and taste of the fish and reptile; and the simple consciousness which, springing from these, passed to us after almost infinite ages of slow evolution and amelioration through tens of thousands of generations of placental mammals, our immediate progenitors.

In the growth of mind, whether that of the race or of an individual, we recognize two distinct processes: 1. The very gradual evolution to or toward perfection of faculties that have already come into existence. 2. The spring into existence of faculties which had previously no existence. For it is clear no faculty (as no organ) came into mature and perfect life at once. Hearing and sight, we are told, developed by slow degrees from the sense of touch; and in the region of the intellect conceptual life was born from ages of receptual, and that from milleniums of perceptual.

Mental growth in the individual and in the race.—Let us now suppose mind growing for millions of years in the way set forth. It begins, we will say, as mere excitability; to that after a long time is added what may be called discrimination, or choice and rejection of, for instance, different kinds of food. After another long interval of almost infinitely slow advance sensation appears, and with it the capacity of pleasure and of pain; then, later still, memory; by-and-by recognition of offspring; and successively thereafter arise reason, recognition of individuals and communication of ideas. Concurrently with these intellectual faculties certain moral functions, such as fear, surprise, jealousy, anger, affection, play, sympathy, emulation, pride, resentment, grief, hate, revenge, shame, remorse and a sense of the ludicrous have also arisen in the nascent mind. We have reached now the mental plane of the higher animals, which is equally that of the human being at about 2 years of age. Then occurs in the child the mental expansion which separates man from the higher mammals—for something like a year the child mind steadily grows from the status of the latter to the status of the human mind. This year in the individual, during which it walks erect, but possesses a receptual intelligence only, not having yet the power of forming either concepts or true words, represents in the race the age of the *alalus homo*, the period of perhaps a hundred thousand years, during which our ancestors walked erect, but not having self-consciousness had no true language. At the average age of 3 years in the individual self-consciousness is born and the infant from the point of view of psychology has become a human being. But we all know that after the attainment of the distinctively human faculty, self-consciousness, the child has still much to acquire both in the way of the expansion of already possessed faculties and in the acquisition of new ones before it is mentally a mature man. Of the numerous faculties which it still has to acquire I shall only mention here the color sense, the sense of fragrance, the human moral nature and the musical sense.

That basic and master human faculty, self-consciousness, occurs, as said, at about the average age of 3 years, but when it first made its appearance in the race it must have done so at full maturity; perhaps at the age of 20, both life and childhood being shorter at that time than they are today. You will see at once why I say self-consciousness must have occurred at first at maturity. Its acquisition at a given epoch supposed a higher mental life than had hitherto existed—such higher life on the part of the race could not have come to the individual before his maturity. To suppose that, it would be a contradiction in terms. The human mind attains its high water mark at maturity (that is what the word means), and one generation could not reach before maturity what the preceding generation had not reached at all. But self-consciousness occurs today at 3 years of age, and we only reach full mental maturity (on the average) at the age of 35. The advance, then, made by the individual from the age of 3 to that of 35, represents the advance of the race between the date of the appearance of self-consciousness and today, the mental status of the 3-year old child today being the mental status of the adult when self-consciousness first appeared. How long has it taken the human mind to grow from mere self-consciousness to its present stature? Not less certainly than several hundred thousand years, the time during which man has inhabited the earth.

Of all the mental faculties below self-consciousness each one has its own time for appearing in the human infant; as, for instance, memory and simple consciousness appear within a few days after birth, curiosity ten weeks after, use of tools twelve months after, shame, remorse and a sense of the ludicrous, all of them about fifteen months after. It is to be noted that in every instance the time of the appearance of a faculty in the infant corresponds with the stage at which the same faculty appears (as far as can be at present ascertained) in the ascending animal scale; for instance, memory and simple consciousness occur in animals as primitive as the echinodermata, while the use of tools is not met with below monkeys, and shame, remorse and a sense of the ludicrous are almost, if not entirely, confined (among animals) to the anthropoid ape and the dog.

As in prehuman so in human psychology, each superadded faculty was acquired in its own time in the history of the race, and that historic period corresponds with the time in the life of the individual into whom the faculty is born today. For instance, self-consciousness appears in the individual at the age of about 3 years—it appeared in the race several hundred thousand years ago. It has been proved by Geiger and others that our color sense was acquired by the race not more than 30,000 years ago. It is acquired by the individual at the age of about 5 or 6. It is thought that the sense of fragrance was acquired by the race later than the color sense; it is also acquired later by the individual. Our human moral nature can not be more than 10,000 years old, for a careful consideration of the records that have come down to us from the early Romans, Hellenes, Hebrews, Egyptians, Assyrians and Babylonians would indicate that as we go back into the past, this faculty tapers down toward the vanishing point, and that if it continues so to taper as we ascend the ages, all of what we distinctively call our human moral nature would certainly have disappeared by the time we had gone back the number of centuries mentioned—that is 10,000 years.

Today the human moral nature in the individual, instead of being born at the age of 3 years as is self-consciousness, or at 5 or 6 as is the color sense, does not come into existence before the average age of about 15 years. As to the musical sense, it is almost certainly less than 5,000 years old in the race, and when it occurs at all, is not usually born in the individual before adolescence.

There are three other laws which govern the acquisition of new faculties by any given race, viz.:

1. The longer a race has been in possession of a given faculty the more universal will that faculty be in the race.

2. The longer a race has been in possession of a given faculty the more firmly is that faculty fixed in each individual of the race who possesses it. In other words: The more recent is any given faculty the more easily is it lost.

3. A study of dreaming seems to reveal the fact that in sleep such mind as we have differs from our waking mind, especially by being more primitive; that in fact it would be almost strictly true to say that in dreams we pass backward into a prehuman mental life; that the intellectual faculties which we possess in dreams are, especially, recepts as distinguished from our waking concepts; while in the moral realm they are those faculties such as remorse, shame, surprise, along with the older and more basic sense functions, which belonged to us before we reached the human plane, and that the more modern mental faculties such as color sense, musical sense, self-consciousness, the human moral nature, have no existence in this condition, or if any of them do occur, it is only as a rare exception.

Let us now compare a few of the faculties which have been already mentioned in the light of the rules laid down. This will give us a definite notion of the growth of mind by the successive addition of new functions. For this purpose we will take simple consciousness, shame, self-consciousness, color sense, the human moral nature and the musical sense.

Simple consciousness.—Simple consciousness makes its appearance in the human infant at the age of a few days; it is absolutely universal in the human race; it dates back certainly to the earliest mammals and probably much earlier; it is only lost in deep sleep and coma; it is present in all dreams.

Shame.—Shame is said to be born in the human infant at the age of fifteen months; it is a prehuman faculty, being found in the dog and in apes, and undoubtedly existed in our prehuman ancestry; it is almost universal in the race, being only absent in the lowest idiots; it is very common in dreams.

Self-consciousness.—Self-consciousness makes its appearance in the child at the average age of three years; it is not present in any species but the human;

it is, in fact, that faculty the possession of which by an individual constitutes him a man. It is not universal in our race, being absent in all true idiots; that is, it is permanently absent in about one in each thousand human beings born into the world. In our ancestry it dates back to the first true man; a race, we are told, unclothed, walking erect, gregarious, without a true language, to a limited extent tool-using, destitute of marriage, government or of any institution; animal, but in virtue of its highly developed receptual intelligence, king of animals, which developed self-consciousness and by that fact became man. It is impossible to say how long ago it was when this event occurred, but it could not have been less than several hundred thousand years. This faculty is lost much more easily and frequently than is simple consciousness. We lose it in coma and also often in the delirium of fever; in certain forms of insanity, as in mania, it is often lost for weeks, even months, at a time; and lastly, it is never present in dreams.

Color sense.—This faculty appears in the individual at the average age of about five years. It is absent in one adult human being out of every forty-seven; it appeared in our ancestors, as Geiger has shown from linguistic paleontology, in the Aryan period probably less than thirty thousand years ago. It is seldom present in dreams, and when it does occur, that is, when any color is seen in a dream, it is generally that color which for good reasons was first perceived by man, namely, red.

Moral nature.—The human moral nature belongs to a much later stage of evolution than any of the faculties so far considered. It does not make its appearance in the individual before the average age of fifteen years. It is congenitally and permanently absent in at least forty human beings out of every thousand. It would seem clear, as stated already, from a consideration of our historic ancestors, from the fact that this faculty rapidly fades out as we ascend into the past, that it can not have existed in the race more than ten thousand years at the most. It is far more unstable in the individual than older faculties such as self-consciousness. It is never present in dreams.

Musical sense.—The musical sense does not appear in the individual before the average age of about twenty years; does not exist in more than half of the members of the race; has existed less than five thousand years in the race, and is never, or almost never, present in dreams, even in the case of professional musicians.

The scheme of mental evolution.—You now clearly see the scheme upon which I suppose the mind (as far as we have got) to have been built. I say advisedly "as far as we have got," because, if the mind has grown in the way set forth, it is still growing and is not built but is in the act of building. No man can ever say positively that his theory (of any fact) is the true one, but I am prepared to say of the above hypothesis that, if it be accepted, it will enable us to understand something of the phenomenon of mind as we observe it, whereas if we should prefer to hold as many do, that the human mind was created independently of any that preceded it by a *fiat* and *per saltum*, then I say deliberately that there is and can be no such thing as a science of psychology, and that every attempt to investigate or explain, to comprehend or divine the *rationale* of the facts observed as to its origin and growth in the individual must remain for ever futile. And if I could find the right words I would bring home to each one who hears me the inextinguishable conviction that, in this idea of evolution, lies enfolded the mystery of the past, the explanation of the present, and the sure prescience of the future—what we were, what we are and what we shall be.

The atavistic theory of idiocy and insanity.—In conclusion, I desire to refer briefly to two corollaries which flow from this hypothesis. The first is, that if it is correct, then all forms of insanity, including all forms of idiocy, are nothing more or less than cases of atavism. In this view insanity is due to congenital absence or imperfection (leading to breakdown) of some faculty or faculties, such absence or imperfection being due to more or less complete reversion to an ancestral type. In my opinion, this view explains insanity and its numerous forms more completely than these can be explained from any other point of view. Upon this view the comparatively recent origin and rapid evolution of the human mind, and especially the rapid mental evolution of the so-called Aryan peoples in the last four or five thousand years, is almost solely responsible for the large number of cases of insanity in the modern civilized world, since the stability of any form, function or faculty in any race is dependent upon the time it has existed in that race, and therefore the more recent a faculty is in a race the more frequently will it be found absent, defective or unstable in the individuals of the race.

Future development of mind.—The second corollary, which is even more important than the first, is that, upon the view here set forth, the human mind at present is not formed, but forming; is not completed, but in process of construction. By slow and dubious steps taken in darkness our remote ancestors wearily climbed to simple consciousness. After another immense interval they reached self-consciousness. But that can not be the end—the cosmic process can not stop there—can not, indeed stop anywhere. Evolution, as far as we can see, has always gone on, is going on today and will always go on. Our old mental faculties are some of them fading out, others advancing toward greater perfection, and alongside of them new ones are springing up, some of which will, without doubt, be of overshadowing importance in the future.

So-called telepathy and clairvoyance seem to be specimens of such nascent faculties. I place in the same class the phenomena of what is often named spiritualism. The labors of the Society for Psychic Research have made it plain to me that these phenomena, as notably in the case of W. Stainton Moses, really exist. And I think a study of the above-mentioned case, together with that of Mrs. Piper and that of Mary J. Fancher of Brooklyn, would compel any unprejudiced person to make the same admission. But to me these are not cases in which outside agents are acting on or through a human being, but are cases in which a given human being has faculties which are not commonly possessed. Whether any given faculty, such as one of those now alluded to, shall grow, become common and finally universal in the race, or wither and disappear, will depend upon the general laws of natural selection and upon whether the possession of the nascent faculty is advantageous or not to the individual and to the race.

But of infinitely more importance than telepathy and so-called spiritualism (no matter what explanation we give of these or what their future is destined to be) is the final fact to be here touched upon.

This is, that superimposed upon self-consciousness, as is that faculty upon simple consciousness, a third and higher form of consciousness is at present making its appearance in our race. This higher form of consciousness, when it appears, occurs at the full maturity of the individual, at about the age of 35, but almost always between the ages of 30 and 40. There have been occasional cases of it for the last 2,000 years, and it is becoming more and more common. In fact, in all respects, as far as observed, it obeys the laws to which every nascent faculty is subject. Many more or less perfect examples of this new faculty exist in the world today, and it has been my privilege to know personally and to have had the opportunity of studying several men and women who have possessed it. In the course of a few more milleniums there should be born from the present human race a higher type of man possessing this higher consciousness. This new race, as it may well be called, would occupy, as toward us, a position such as that occupied by us toward the simple conscious *alalus homo.* The advent of this higher, better and happier race would amply justify the long agony of its birth through the countless ages of our past. And it is the first article of my belief, some of the grounds of which I have endeavored to lay before you, that a race is in course of evolution.

ORIGINAL ARTICLES.

HYDROPHOBIA.

Read in the Section on State Medicine, at the Forty-eighth Annual Meeting of the American Medical Association held at Philadelphia, June 1-4, 1897.

BY CHAS. H. SHEPARD, M.D.
BROOKLYN, N. Y.

This paper is presented more with the idea of calling attention to enforcing the fact that there is a reliable remedy for animal poison, than to offer any new developments in regard to hydrophobia. Little that is new and undisputed has been discovered since the report of the American Medical Association, in 1856. We are still confronted with contradictory theories and strange anomalies, which are only to be explained from the vantage ground of one who realizes that disease is not an entity, but rather a remedial effort, and that relief comes only by our ability to recognize and assist the vital forces in their inevitable conflict with all foreign material.

Although hydrophobia is one of the rarest and most fatal of acute, infectious diseases, and is produced only by inoculation of a specific animal poison, which manifests itself by symptoms due to a disturbance of the central nervous system, it is mitigated by the more important fact that the period of incubation is longer than that of any other acute specific disease. This period is variable, rarely less than a month, in some cases reaching nine or twelve months, the average being six or seven weeks, which gives opportunity for remedial measures, that as we will endeavor to show, are ample to eradicate the poison.

The etiology of hydrophobia is so well known that it needs but a few words of description; mainly coming from the saliva of dogs, rarely from cats or other animals, it is a well recognized fact that the disease never originates in the human species. Its spontaneous origin is confined to the lower animals that do not perspire. The investigations of scientists all over the world have as yet failed to determine the true cause of this terrible malady, although the fact seems to be well settled, that the disease occurs much more frequently among the male than among the female dogs or other animals. Inoculation may arise from a bite, scratch, or from a lick upon an abrasion. Instances have been given where the disease came from the lick of a dog that was not mad.

A puzzling case occurred some years ago in England. A boy 14 years of age, while playing with a Scotch terrier, was bitten slightly on the hand. Three weeks later he became ill and died in terrible convulsions. The physicians pronounced it a genuine case of hydrophobia, but a girl who had been bitten by the same dog appeared to have suffered no harm, and, more remarkable still, the dog was examined by a competent veterinary surgeon, and pronounced perfectly healthy. Such cases are not uncommon.

When preventive measures are adopted as soon as possible, the larger number of persons escape. Children are the greatest sufferers, from being helpless and more exposed, and their cases are not open to the charge of simulated or spurious disease, and at the same time they are a complete refutation of the theory held by some authorities that there is no such disease.

The fact that during the period of incubation there are commonly no symptoms, is liable to lead to a sense of false security. But that is the time to adopt vigorous measures of prevention. Occasionally there is pain or discomfort at the seat of the wound, and sometimes mental depression, which may arise from anxiety regarding possible consequences. Even the onset of the disease is rarely attended by pain or inflammation in the wound. The first evidence of the impending disorder is usually mental depression, disturbed sleep, discomfort about the throat, with difficulty in swallowing liquids; even the attempt occasions spasms, which soon involves the muscles of respiration. The intensity of all these symptoms increase within a few hours, until the mere sight of water will cause a spasm. The reason is frequently lost, and the end from exhaustion is assured in from one to six or eight days.

The varieties in this disease are as great as in any other, because each case is modified by the condition of the system, and the vital reactive powers of the individual.

If there is a prospect of relief from the horrors of hydrophobia, this relief may well claim our earnest attention. It is well known that from the bite of a rabid dog there is a period varying from seven days to six months, before the more acute symptoms manifest themselves. This gives ample time to eliminate the poison from the system. In "Todd's Clinical Lectures," occurs this passage, "Large evacuations by sweating may be employed more freely and with less disadvantage to patients, than by any other secretion." This is also demonstrated by the fact that many diseases are daily being cured by some form of sweating bath, and that physicians are more and more using that form of treatment. In China, and other countries, as well as our own, sweating has been successfully used in the elimination of malarial poison. Another proof is that in some Eastern countries the sweating bath is used to cure the poison of snake bite, which is much more rapid in its action than the poison from the saliva from a rabid dog. It will also readily be seen that treating this malady from the outset is a very different thing from waiting until the poison has become absorbed and permeated the whole system, and the paroxysms have set in, when in truth there is little hope of cure under any treatment.

Hydrophobia belongs to that large class designated as ferment diseases, which depend upon the introduction and development in the system of ferment germs. Enteric fever and erysipelas are familiar examples. Simple absorption has sufficed to inoculate the patient, but in the majority of instances the skin receives more or less abrasion, and the germs are either implanted in the epithelium beneath, or introduced directly into the circulation. The abrasion may heal kindly, but in a varying time, depending upon many factors, an irritation at the seat of the abrasion, accompanied with darting pains, announces the onset. Unlike other diseases, the blood appears not to be a good soil for the development of the germs, which however circulate with it until they find the soil, or tissue, best adapted to them, and then the real havoc begins. In the dog and the man, the three pairs of salivary glands, the parotid, submaxillary, and sublingual, appear to furnish the required conditions, and to be the main seat of the lesion. The congestion of the nervous centers that so directly ensue, is probably consequent upon changes in the structure of these glands. Every physician knows well how speedily severe nervous symptoms follow such changes, how intimate the sympathy is between the glandular organs of the mouth and throat and the nervous centers at the base of the brain, and what violent hysteriform seizures often ensue in such cases. With the involution of the great respiratory tract of the nervous system come difficult respiration and its train of associated symptoms. At the same time it is more than probable that the nervous system suffers from the more direct poisoning caused by the presence of germs in the circulation, but not because they are a specific nerve poison, for when a full dissection is performed, no evidence of it is found in the nerve centers, and this excludes the nerve poison hypothesis.

In the McCormick case, as reported by Dr. Hammond, June 1874, microscopic examination revealed disease of the cortical substance of the brain, disease of the medulla oblongata, and disease of the spinal cord, also disease of the pneumogastric and hypoglossal nerves. The nerve elements were broken down and oil had taken their place, and this has been found the general direction of the disease, with slight modifications in different cases. Fatty degeneration of the nerve substance was a marked symptom.

The question quickly arises, what best can be done to arrest the action of this poison? Nature does everything possible by arousing every emunctory to action and, as in all cases of poison or morbid matter in the system, the leucocytes are called upon for their most vigorous action to relieve the patient. It is claimed that immediate suction of the wound has saved many patients. Good authorities believe that the virus remains localized, for a time, in the cicatrix, and that cutting it out even after the original wound has healed, may serve to avert the disease.

To diminish the production of rabies in the dog, Fleming, one of the most distinguished veterinary surgeons, recommended that dogs should be muzzled, except in times when the disease is epidemic, that they should be placed under good hygienic conditions with a heavy tax upon every animal, and that all vagrant dogs should be killed. It is claimed by some, among them Fleming, that rabies has spontaneously originated in the dog, in consequence of exposure to extremes of heat and cold, ungratified sexual excitement, maltreatment, insufficient food, etc. Roucher, another authority, also maintained the same idea.

Opposed to this is a long array of eminent authorities who claim that rabies does not originate in the dog otherwise than by inoculation with the virus of a rabietic animal.

In the pathologic anatomy of the disease we are also involved in a mass of contradictions. Careful microscopic examinations of the brain and spinal cord, by medical experts, have been attended with entirely negative results. In some few cases there was found fatty degeneration of the nerve-cells, notably that published by Dr. Hammond in 1874, in others simple congestion of the vessels, but in the whole list there was no lesion found that was peculiar to hydrophobia.

In reporting this condition of things, the *Medical Record* stated, May 25, 1878: "We are forced to the sad conclusion that, with the present means at our command, every case of hydrophobia is necessarily fatal."

Dr. Hammond, in his report previously referred to, endorsed the plan suggested by Bourrel and also detailed by Fleming in his treatise on rabies, of having the incisor teeth blunted. So far as dogs treated that way are concerned, this was claimed to be an absolute preventive, but non-rabid dogs have been known to communicate the disease. It is a well known fact that the germs of this poison are sometimes present in the saliva of dogs that are apparently healthy, and particularly frequent in that of the spitz. It is also known that the bite of a man in anger may inoculate a man whom he bites, with poison that produces disease, if not hydrophobia. Instances are on record of a woman while in anger nursing her infant, thereby bringing on convulsions and endangering the life of the child.

The pathologic changes in the nerve substance are but the local exhibition of the general systemic poisoning. In the effort to throw off this poison a small amount of morbid matter adjacent to living structure is dissoved by the leucocytes, and is forced out of the system by way of the natural emunctories. When the system is in the throes of a vital struggle with this morbid material, there can be no excuse for thrusting upon it more of the same material, even though it be in attenuated form. The human system, when laboring under morbid influences, needs but those elements which can add vigor to the vital resistance, and the fluid which patrols the entire body, should be strengthened rather than further decomposed and disorganized by the addition of extraneous and poisonous matter.

The Pasteur treatment is the accredited method for those who have been bitten by a rabid animal, but this, like the antitoxin treatment, is simply sending one poison after another in the system, and whatever the result the victim is the chief sufferer. The Pasteur treatment has not proved uniformly successful, and in those cases where it was apparently so, it is open to question whether the patients might not have recovered without any treatment. It is well known that during the first few years of the experimental inoculations for rabies, so many deaths occurred among the patients that Pasteur himself became alarmed at his own work. Since that time, from the improvement in the treatment, the death-rate has lessened, due to the dilution of the curative lymph.

It is well enough, and most commendable, to discover the microbe which, as stated, appears "to be the veritable and sole factor in the malady," but facts go to show that the microbe is the result of the disease, except in inoculation.

Pasteur found no indication of an incubation period shorter than seven days, and he never claimed that he had discovered a *cure* for hydrophobia, but simply that a person who had been bitten by a presumably mad dog and within a few days was inoculated with attenuated virus, would not develop hydrophia; if a certain time had elapsed after the bite this preventive treatment was of no use whatever.

The London *Lancet*, of Oct. 31, 1885, says: "We can not but think that Pasteur's inferences are sanguine and premature." In the year 1895 the *Lancet* published a statement from Dr. Magner, in which he pointed out that Pasteurian statistics were very misleading, and quoted from a report of the Registrar-General of England, to show that in the five years preceding the establishment of the Pasteur Institute, the number of deaths from hydrophobia were 155, whereas in the five years thereafter they reached 159. He thought that was a strong argument that the Pasteur Institute had no effect in diminishing the deaths from hydrophobia. An article in the Paris *Journal of Medicine*, by Prof. Peter, stated that the inoculations pretended to be antirabic by M. Pasteur were in principle nonsense, and in practice deceptive. Statistics have shown that the mortality from hydrophobia, in and around Paris, the seat of the Institute, has not been in any way lowered, but on the contrary, has increased ever since Pasteur began his inoculations. In 1895, 272 persons died of hydrophobia after undergoing the Pasteurian treatment, which ought to have saved them from any attack of the malady. . . In 1866, a girl named Pauline Kiehl, was taken to the Institute, but as hydrophobia had already set in Pasteur declined having anything to do with the case. The girl was then taken to Dr. Leon Petit of Paris, who cured her by the vapor-bath treatment. . . . Dr. Lutaud, editor of the *Journal of Medicine* of Paris, with straightforwardness asserts that Pasteur does not cure hydrophobia, but he gives it. . . In 1894, Dr. C. W. Dulles of Philadelphia, made a report to the Pennsylvania Medical Society, of his special study of hydrophobia, covering a period of over ten years. His figures give an average, from a total of seventy-eight cases, of one per annum to every 4,500,000 of population, with an excess of cases in the vicinity of Pasteur Institutes. In fact, he charges directly that not only has Pasteur's methods "increased the number of deaths from hydrophobia," but that "there has been added to these a large number of deaths due to inoculation of what ought to be called Pasteur's disease." . . . Dr. Dolan, editor of the *Provincial Medical Journal*, taking a general survey of Pasteur's methods and his numerous failures, says that "Not only does Pasteur not protect from the disease under the very conditions demanded by himself. but he has added a new terror to it by the introduction of paralytic rabies."

In Long Island City, on April 25, 1897, a strange dog severely bit a 6 year old boy named Charles Silk. Two days thereafter the child was taken to the Pasteur Institute in New York and a course of treatment commenced at once, which lasted fifteen days. After completing the course at the Institute the mother of the child was told that her son was insured against dog bites for ten years to come, but three weeks from the day of being bitten, the boy died, a pronounced case of hydrophobia.

Better than Pasteur institutes, and better than all other remedies, or rather preventives, would be what is proposed by an eminent English writer, Mrs. Maynell, in the London *Chronicle* and that is the utter extinction of the canine race, holding that the life of one child is of more value to the world than that of all dogs, and that one of the inevitable results of our advancing civilization will be their extinction. While the dog forms a prominent feature of the domestic life of our day, the services he renders are by no means an adequate offset to the danger with which his presence continually menances the community.

The Pasteurian treatment is a grevious mistake, although it is as yet the only method that has medical sanction. There is a simpler, safer and more scientific treatment for the dreaded disease, based not upon the old fashioned practice of putting foreign matter into the system, but on the more modern and exact principle of eliminating the poisonous taint. That is the hot air or vapor bath treatment as practiced in many lands, but particularly by Dr. Buisson, formerly of Paris. By this means patients have been cured, even after hydrophobia had set in.

In the year 1826, Dr. Buisson was called in to attend a woman attacked by hydrophobia. According to custom he bled her, and happened to wipe his hands on her handkerchief, covered with saliva. "Perceiving a mark on the first finger of my left hand," he writes in a book published in Paris in 1855, "I became aware too late, how imprudent I had been. As soon as I reached home, I cauterized the wound with nitrate of silver. On the seventh day I experienced a sharp pain in the region of the scar. Imagining, however, that it was in consequence of the cauterization, I paid no great heed to it, but the pain became so intense that I was obliged to put my arm in a sling. The pain grew more and more acute, commencing at the first finger and following the radial nerve till it mounted to the forearm. The paroxysms lasted two or three minutes, with intermissions of five or six minutes. At each paroxysm the pain spread to the length of several centimeters, when it passed the elbow it became intolerable. My eyes were extremely irritable, and felt as though likely to start out of their sockets. I was painfully affected by light, and consequently by all luminous bodies, such as glass and metals. My hair seemed to stand erect. My body seemed lighter than air; I believed that by springing from the ground I could have lifted myself up to a prodigious height. I had tightening of the throat, constant nausea, salivated much, and expectorated incessantly. I felt that my sublingual glands were swollen, but when I wished to assure myself of the fact by looking at them in a glass I was unable to carry out my design on account of my eyes. I had a constant longing to run and to bite, and my only alleviation was to walk quickly up and down my room, biting my handkerchief the while. I had a horror of water."

Ordinarily there is but one result to such a condition as this. "For some time past," continues Dr. Buisson, "I had been persuaded that a vapor bath was able to prevent, but not to cure hydrophobia. My thoughts being occupied solely with death, I sought that which was the most prompt and least painful, to put an end to my life. I resolved to die in a vapor-bath. I took a thermometer in my hands, fearing that the heat I desired might be refused me. I had been but a few minutes in the bath before I felt a change for the better. This gave me hope. At 127 degrees F. I was cured. At first I believed it was merely a long intermission from pain, which would be terminated by contact with the air outside the bath. After the bath I dined and drank with ease, and went to bed and slept well. From that day to this, nearly twenty years, I have felt no sort of pain or uneasiness."

Dr. Buisson again says: "Experience has proved to me that hydrophobia may last three days. The cure is sure by following my system the first day, uncertain the second, impossible the third. Who would wait for the last day, knowing my means? One would not even wait for the malady, one would always prevent it. Hydrophobia never shows itself before the seventh day after the bite, and one can then go a long journey to procure these baths, called Russian."

The *Lancet* says: "Hydrophobia was cured by the late Dr. Buisson in his own and eighty cases by vapor baths, raised rapidly to 135 degrees F., and more slowly to 145 degrees F." "A vapor bath," writes Dr. Buisson, "prevents the development of hydrophobia and cures the malady when developed. In order to convince all sensible persons that I am really in earnest I offer to inoculate myself with the disease. This fact should be a sufficient guarantee of the certainty of my method of cure."

It is interesting to state that in London there is now established a Buisson institute, under the care of a qualified physician, *for the gratuitous treatment of* hydrophobic cases. A number of cases of undoubted hydrophobia have been successfully treated by means of these baths in India, and the Viceroy of India has notified Mr. F. E. Pirkis, R. N., of the London Buisson Baths, that the government will afford facilities for the placing of Buisson baths for the treatment of hydrophobia, in government hospitals and dispensaries in India. Twenty baths for that purpose are being immediately dispatched. In looking over a late paper from Calcutta, it was noticed to contain an advertisement of thirty-four Buisson Baths, located in different parts of India, where that treatment could be obtained free by needy sufferers.

There is no possible doubt as to the value of the Turkish bath in all disorders of the ferment class, and whether it is competent to the complete eradication of the poison, or to arrest destructive tissue changes when once they have thoroughly begun, will appear doubtful only to those who are not familiar with the wonderful restorative action of heat when used in its higher potency. The simple treatment of a hot air bath has actually cured the disease in the last stages and restored the patient when in the extreme horrors of rapidly approaching death. A prompt use of the hot-air bath in every case of a bite from a dog can not but do good, even if there is no question of the animal being rabid, and when the animal is mad it is a safe and effective remedy. Whoever is willing to investigate the merits of the hot-air bath will soon learn that it has a valid claim to the title of certain cure for hydrophobia.

In Brooklyn, N. Y., June, 1874, a case came under my supervision. A suspected dog was confined but broke away and in his career of biting other dogs also bit a Prospect Park laborer, one George Wagner. As the dog was to all appearances suffering from rabies he was immediately killed. The man's wounds were cauterized with nitrate of silver and on the third day thereafter he was brought to the Turkish bath. He was bitten through the palm of one hand and partly through two fingers. He complained of what seemed like neuralgic pains in the hand and arm, which were swollen, and also pains in the head, back and throat. He underwent the processes of the bath twice daily during one week and once daily for two weeks longer. The baths were administered with exceptional vigor in his case. Soon every unpleasent symptom vanished and for many years afterward he was well and hard at work.

Dr. M. Hermance, also of Brooklyn, N. Y., in 1877 saved a boy from the agonizing death of hydrophobia, by the use of the vapor bath, which was applied while the patient was tied down in bed. In about three-quarters of an hour after beginning operations a profuse perspiration was induced. When he began to sweat freely signs of returning consciousness appeared, which increased as the perspiration was continued, until in the space of about two and a half hours he was fully restored to consciousness, with a perfect relief from all his hydrophobic symptoms, the pain in the bitten hand and arm included, of which he had complained very much in the intervals of consciousness between his convulsions.

There is also most positive evidence regarding this form of treatment from Wilmington, Del. In the year 1869 three children of that place were bitten by a rabid dog. This dog also bit a heifer, a cow and two other dogs. The four animals soon afterward died of hydrophobia. The children were placed under the care of Dr. John Cameron of that city and by him were taken to Philadelphia and there subjected to the Turkish bath daily for two weeks. Although the wounds were very severe and the discharge from one of them was of the color of verdigris for several days, they healed without difficulty and no symptom of the malady has been manifested since.

In 1866 Rev. J. J. Curran of the Industrial School, Arlington, N. J., published a case which occurred under his care. One of the pupils named Klee was bitten on the hand by a dog on January 2. As the wound healed rapidly nothing more was thought of it, but on January 22 unmistakable symptoms of hydrophobia manifested themselves and increased for two days, when there appeared no possible hope for him. Then a small kerosene oil stove was lighted and placed on the floor; on top of this was placed a pan of boiling water and over all a chair, on which the boy was seated. Around the chair and boy and vapor-making machine were wrapped several folds of blankets, pinned about his neck and fitted so that the steam was retained about his body. He was also given a dose of sweating medicine and in five minutes the perspiration was streaming from every pore of his body and in ten minutes after he said: "The pains are all gone!" He was kept in this condition for about half an hour. The result was that the boy was cured and two months after he was as well as he ever had been and so continued.

The natives of Australia, and also of India, have a successful habit of at once taking violent exercise on beginning to feel ill. This is the principle of the Turkish bath treatment, that is, to relieve the system of its impurities by sweating.

Sir John Drummond Hay, who was many years English minister in Morocco, long before Pasteur's time, stated that the Arabs there cured hydrophobia by sweating. The patient was swathed in woolen covering till all but smothered, placed in a small tent (these tents are always of black camel's hair, much more impervious than canvas) and then the tent was closed so as to exclude air as much as possible and the patient left until profuse perspiration carried off the poison. This treatment was found invariably successful.

A St. Petersburg newspaper states: "We are informed by good physicians that if the patient, immediately after being bitten, will go into a bath and stay there seven days he will have excellent chances of recovery. The poison in the blood will be eliminated by a steady and vigorous perspiration. Some physicians have attained good results by washing the wound with warm vinegar and then applying hydrochloric or muriatic acid."

There is undoubtedly an hysteric or "mental hydrophobia," as it is sometimes called, induced by emotion, or through fear of the disease after having been bitten, which may lack many of the characteristic symptoms of the true affection and differs from it notably in its rare fatality. Such cases, serious enough to the patient for the time being, would be most easily and agreeably treated by the Turkish bath. Herein would come one of the great advantages to the community, which every city would enjoy by having, what would be most desirable to all, a public Turkish bath, that would be open to such cases as well as to any other. A few days' or, at most, a few weeks' treatment at such an establishment would put the patient out of reach of any danger from hydrophobia.

Some twelve years ago, four children, living at Newark, N. J., were bitten by a dog supposed to be rabid, and more than $1,000 was subscribed to send them to Paris that they might undergo Pasteur's treatment. If the people were only awake to their best good and would subscribe liberally for public Turkish baths they would have a better and surer remedy right at their own doors.

On March 28, 1897, Dr. Frank D. Gray, in Jersey City, was bitten by a St. Bernard dog that had shown some slight symptoms of rabies. Evidently not knowing any better way, Dr. Gray sailed for Paris to take the Pasteur treatment. Had he been aware of the eliminating power and healing virtues of the Turkish bath he could have remained at home and saved himself the mental torture as well as the expense incident thereto. It is very pleasant and desirable to go to Paris, but to "wash and be clean," is much more desirable.

The conclusion that is forced upon us by these facts is that in all cases of infectious disease our chief efforts should be directed to promoting the eliminating power of the patient. This is working in harmony with and assisting the vital resistance to disease. Whatever tends to invigorate the individual enables him the more quickly and surely to surmount the difficulty. Herein lies the most important element. When it is understood that in the proper application of heat, and in that we recognize all forms, whether it be the use of hot water, the Russian bath or the above all most desirable Turkish bath, and the fact remains that in heat we have an agent capable of counteracting the poison of rabies, then it may well be asked, What poisonous influence can resist its potency? Knowing this we should do all in our power to arouse the the public mind to the value of the public Turkish bath, which should be established by the people in every city in the land and so conducted that its blessings would ramify through every stratum of society. Thus would we hasten on the time when hydrophobia will cease to be a terror in the land and disease will not be the inheritance of every child, but rather that good health will be the pride and possession of every citizen.

A STUDY OF THE BLOOD IN TUBERCULOSIS.

OR THE RELATION OF LEUCOCYTES TO THE BODY AND THEIR AID IN INTERPRETING VITAL PHENOMENA.

Presented to the Section on State Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY A. MANSFIELD HOLMES, A.M., M.D.
Lecturer on Hematology in the University of Colorado; Hematologist to St. Joseph's Hospital; Member of Denver and Arapahoe and Colorado Medical Societies, Pan-American Medical Congress, etc.
DENVER, COLO.

No branch of science appeals to us so deeply as the study of life; and it is the object of the following research to investigate some of the causes which tend to shorten life, and if possible to devise means of detecting these causes before they have produced permanent injury to the individual.

In presenting the subject I feel very keenly my inability to do it the justice which it deserves. But realizing that success is achieved in any line of research only after repeated efforts, and often after many failures, I am encouraged in the undertaking, believing that the closer we adhere to nature, the nearer we shall arrive at the truth. Also I regret that the limited time which is necessarily allowed for the presentation of the subject, prevents my giving proper credit to many authorities whose researches have rendered me valuable assistance in forming the following deductions.

A Preliminary study.—The animal organism has been the subject of study and discussion as long as any now before the scientific world. Previous to the time when the microscope came into use, vital phenomena were very imperfectly understood. But since that date much progress has been made.

A study of the living organism may be made with reference to its structure or morphology, or with reference to its functions. In former papers,[1] dealing with the blood in tuberculosis, I have considered almost exclusively the morphology of cells and their physiologic chemistry. In these departments I have pointed out numerous analogies existing between leucocytes and the larger organism. But the present paper will be more in the line of

A study in functions.—I shall attempt to point out, interpret and classify the phenomena of cell life, and to ascertain if analogies cease with the morphology, or if they are also extended to the functions.

1. In studying the functions of a living organism, I shall begin with the simplest form of animal life, the leucocyte. I shall first note cell phenomena, and then interpret and classify them, with reference to ascertaining how far they reveal the conduct or behavior of the cell, or the plan or purpose of its actions. With this in view, a small quantity of fresh blood or lymph is prepared in the form of a hanging drop.

Among the first phenomena noted are those pertaining to cell metabolism. Cells are observed to partake of food, grow, develop to maturity and finally die, or divide and form two new cells. Furthermore, if an artificial stimulus is applied, they contract and move away; or, in other words, they make an effort to avoid the irritant. If pathogenic germs are introduced into the hanging drop, the cells approach the invaders, and often an immediate warfare ensues. If a single cell is observed, and the enemy is too powerful for a single-handed combat, the cell moves away and in a short time a group of cells appears and joins in the attack. These interesting cell phenomena have been observed and reported by Metschnikoff, Leidy, M. Greenwood, Kanthack and many other excellent authorities.

---

[1] Medical Record, Sept. 5, 1896; March 13, 1897.

Hence, a study of cell phenomena is evidence that cells experience sensations; that they respond to irritation; that they possess the power of adjusting their actions with reference to the conditions surrounding them. In other words, they feel the need of food or experience hunger; they make a struggle to obtain food, which is a struggle for existence; they recognize the presence of an enemy, and exert themselves in self-defense or self-preservation; they manifest the disposition to protect their companions against enemies; and by development they reveal the phenomena of differentiation of functions and structure, and show a tendency to put into execution the principles of co-operation and division of labor; and finally, they reveal the phenomena of reproduction.

If leucocytes exhibit such remarkable and independent behavior when extracted from the larger organism, and are independent of its central nervous system, it is evidence that the actions or conduct of each cell emanate from within the cell itself. Hence, each cell is endowed with a something which produces vital phenomena.

2. The larger animal organism is an aggregation of cells, or smaller living organisms. These cells become classified into groups by the process of differentiation, and each group is especially employed in performing some particular function. Now, since it is observed that the cell is endowed with that which produces vital phenomena, it seems rational to infer that the vital phenomena of the larger organism is the aggregate of the phenomena produced by these smaller organisms or cells.

3. Finally, the social body, or the body politic, possesses the characteristics of a complex organism. Men divide themselves into groups and classes, each from repeated effort acquiring skill sufficient to perform some particular function; each, in some respect, differing from the others, and yet all co-operating for the good of the whole.

Classification of organisms.—Thus, we find three distinct realms of life, each being a part of a larger realm. The cell is a living organism on a low plane of development; it is a vital unit and occupies the first biologic magnitude. Man is a complex organism on a higher plane of development; he is a multiple of units and occupies the second magnitude. Humanity is a more complex organism, a compound multiple of units, and occupies the third magnitude. On the other hand, we find in the cell a localized center in the nucleus; in the individual, a localized center in the brain; while in the social organism we find a centralization of functions in the seat of government. Furthermore, there is an environment or realm for each of these organisms: for the cell, for man and for humanity.

It is not our purpose in this research to enter into a discussion of psychic problems. But a study of life in its various realms is evidence that there is within every living organism a something which enables it to adjust itself to its environment. And in bringing about this adjustment, vital phenomena result from acts emanating from within the organism itself. Hence, the laws by which these acts are governed are the laws of the organism. The laws by which cells and their phenomena are governed are the laws of biology. The laws by which individuals and their conduct are governed are the laws of sociology; but from the many analogies existing between these smaller and larger organisms, it would seem that the laws of sociology are simply the laws of biology extended to a wider realm.

System of interpretation.—In former papers I have outlined, in part, the fundamental principles of a system of interpreting vital phenomena. This system is based upon what I believe to be rational hypotheses. These may be formulated as follows:

1. That there is a system of life realms, each realm being a part of a larger realm.
2. That there is a continuity and universality of the laws of life.
3. That the laws in force in the various life realms run in parallels and are analogous.
4. That the phenomena in each realm have analogues in each of the other realms.
5. That a study of the laws and phenomena in one realm will lead to the discovery and interpretation of their analogues when we enter other realms.

Therefore, resting upon these hypotheses, a study of the larger and more complex body will furnish a key for interpreting the laws and phenomena of leucocytes. And, inversely, cell phenomena will give us a key to the larger body.

Factors in organic development.—Now, since every living organism, consciously or unconsciously, tends to adjust itself to its environment, in bringing about this adjustment, there is a change or differentiation in its functions; and, as a result of differentiation in its function, there follows a corresponding differentiation in its structure or morphology. Hence, during the course of the natural development of an organism, as it readjusts itself to a constantly changing environment, there follows both a physiologic and morphologic differentiation. This is true of a cell, an individual or a nation. Therefore, there are three important factors to be considered in the study of organic development: 1, the condition surrounding the organism, or its environment; 2, its functions; 3, its structure or morphology.

The law of differentiation.—Further, when such interesting cell phenomena are observed in a hanging drop, after the cells are removed and have no further connection with the larger body, we may ask what may be expected of such cells if they become differentiated into tissue cells and become a part of the organized body? The problem is difficult of solution. But if we may utilize the phenomena observed in one realm of life to interpret those observed in other realms, we may infer from observing the result of evolutionary development in larger organisms, that when a cell undergoes differentiation its former functions are not lost but, on the contrary, strengthened, developed and differentiated.

In this connection, we may ask what becomes of the infant when it attains adult life? After attaining a certain degree of functional development it takes a place in the social organism and, after acquiring sufficient skill, performs a part of the complicated labor of humanity. If it is a strong organism its functions will be equally strong, or if a weak organism the functions will be equally weak, and the social body will be strengthened or weakened accordingly.

Hence, it would seem that in a similar manner, when a wandering cell or leucocyte becomes a tissue cell, that it will continue to be a center for the exercise of its inherent functions, in a similar manner to that before becoming differentiated; but that it will take upon itself more complicated duties. If it is a strong cell its functions will be equally strong, or if a weak cell they will be equally weak, and the larger organism will be affected accordingly.

Hence, acting upon the assumption that there are definite relations existing between morphology and functions, and between functions and environment, and that these relations are governed by laws, I began the study of tuberculous blood, believing that I might find morphologic appearances in the blood elements characteristic of this disease.

Etiology.—The etiology of tuberculosis has been involved in uncertainty. This much, however, is now generally accepted: that it is produced by the tubercle bacillus. Some authorities claim that bacilli are the sole factors in bringing about the disease. From a somewhat extensive study of the blood in this disease, I feel justified in stating that if we stop at this point only a part of the truth is expressed. These studies have convinced me that it is not only necessary for bacilli to enter the animal body, but that they must find the necessary conditions for propagation before the diseased condition known as tuberculosis becomes established. In this connection it is a well recognized fact that tuberculosis is associated not with strong tissues, but with tissues that are more or less weakened. Therefore, one object of this paper is to show, from a study of the blood, that there must be a previous condition of diminished resisting power of the tissues which renders them a fertile culture medium for the pathogenic germs, before the germs begin to develop; or, in other words, that tuberculosis is preceded by a pretuberculous stage, which in reality is as much a stage of the disease as the ovum represents a stage in the life history of the future organism. In the first instance, if the body tissues furnish a fertile culture medium for the bacteria, as soon as they enter the tissues germ genesis begins and a germ colonization becomes established. In the second instance, if the ovum furnishes a fertile culture medium for the sperm, as soon as the sperm enters it cell genesis begins and a cell colonization becomes established. The first colonization, if not checked in its progress, ultimately develops into an active tuberculous condition; the second colonization, if not checked in its progress, ultimately develops into a more or less mature organism.

Therefore, in searching for the source of the disease, we must antedate the beginning of active germ development in the weakened tissues by passing back to the time when the tissues begin to lose their resisting power and thereby become a fertile soil for the germs. The question which appeals to us most forcibly at this juncture is: Can the condition of feeble resistance of the tissues be detected before the bacilli form a colony and the tissues begin to disintegrate?

Factors in culture development.—A further argument on this line is one which every bacteriologist knows to be true, *i. e.*, that before he can grow a culture, three things are absolutely necessary: 1, a culture medium more or less congenial to the growth of bacteria; 2, living germs; 3, conditions of temperature, moisture, light and atmospheric pressure surrounding the culture medium, favorable to growth. An artificial culture medium may be as perfect as can be prepared, yet if it be kept at a boiling or freezing point the culture will not develop. Therefore, with a congenial culture medium and living bacteria, unless the surrounding conditions are favorable, there will be no culture formation. Many competent observers have reported experiments which show that bacilli may remain inactive in an uncongenial culture medium and yet retain life; but when the conditions become favorable to development they immediately begin to multiply. Whether we consider artificially prepared culture media, or the tissues and fluids of the animal organism, these facts are equally true.

This theory, therefore, furnishes a rational explanation for the unequal susceptibility of various persons to tuberculosis. And this explanation rests upon the hypothesis that tubercle bacilli gain admittance to the tissues of the animal body more readily, and propagate more vigorously, when the tissues are in a definite or specific pathologic state.

The relation of leucocytes to the body.—This brings us to the most important part of our subject, viz.: The relation which leucocytes bear to the larger tissues of the body, and their aid in revealing the condition of these tissues which renders them a congenial culture medium for bacilli.

It matters little in this study which theory of cell genesis is accepted, viz.: That leucocytes are tissue formers, or that tissue cells are leucocyte formers. In either case cell genesis results from cell division, and by the process of development and differentiation there is a transformation from one state through a series of changes into another state. Hence, it matters little in which direction the cell differentiation takes place; whether it takes place from leucocytes toward tissue cell; from tissue cells toward leucocytes, or whether it takes place in both directions. In either case a reciprocal relation exists between the proximate and remote state of the cell as well as between the parent cell and its offspring. Therefore, it is the intention of this study to show that it is possible, from a study of the leucocytes, to make a diagnosis of approaching active tuberculosis before the larger tissues of the body show evidence of breaking down.

The basis for diagnosis.—If we accept the theory that leucocytes are tissue formers, then it is evident that if they are deteriorating before they become differentiated into tissue cells, that the tissues themselves will eventually possess the same characteristics; or on the other hand, if we accept the theory that tissue cells are leucocyte formers, it is also evident that if the tissue cells are weak and manifest a tendency to disintegrate, that the leucocytes will possess the same characteristics. Consequently, in either case, in estimating the resisting power of the larger tissues we must ultimately depend upon the leucocytes. Therefore, it is upon the following hypothesis that a diagnosis is formed: That disintegrating leucocytes form, or are formed by, weak tissues and weak tissues furnish a congenial soil for the development of bacilli.

Blood changes.—A careful study of the blood reveals comparatively uniform sets of phenomena for health and for each variation in the body tissues. Hence, the relation between the blood elements and the body tissues becomes an important factor when we seek to discover the beginning of pathologic processes. The blood changes which take place during the progress of diseases are exceedingly numerous. The ability to correctly interpret all cell phenomena, many of which are now looked upon without conveying any significance, would no doubt be the means of explaining what are considered obscure conditions.

It will be generally conceded that immunity, idiosyncrasy and predisposition are terms used for processes or conditions of the living organism concerning which we possess very little knowledge. And until we possess a better knowledge of cell phenomena many of the phenomena of the larger organism will no doubt remain in obscurity.

Blood changes in tuberculosis.—On comparing the phenomena of the blood elements in various diseases with those of normal blood many differences become apparent. Hence, a definite combination of these differences is frequently recognized as being significant of a definite pathologic condition. In study of the blood in tuberculosis I have recognized numerous cell phenomena which have invariably existed, to a greater or less degree, according to the progress which the diseases has made. I have interpreted these phenomena as signifying:

A. Irregular cell genesis and, B., irregular cell metabolism. These differences may be recognized, *a*, from variations in the morphologic structure of the cells, and *b*, from variations in the staining properties of the cell tissues.

A. Irregular cell genesis may be subdivided into: *a*, Defective cell production, and *b*, excessive cell production.

B. Irregular cell metabolism may be sudivided into: *a*, Irregular cell differentiation, and *b*, excessive cell disintegration.

Irregular cell differentiation may be subdivided into: *a*, Defective cell development; *b*, perverted cell development, and *c*, excessive cell development.

A few of the forms and characteristics of irregular cell differentiation are the following: 1, Giant cells; 2, dwarf cells; 3, cells with poorly differentiated nuclei; 4, cell bodies having poverty in granules. These and many others are probably the phenomena of cells of low vitality. In this connection I have particularly observed that cells of low vitality usually possess feeble differentiating power, and this is shown by their nuclei.

Cell disintegration.—It is but one step from malassimilation to disintegration. This is true of the larger organism and equally true of the cell. Cells of low vitality are probably first to undergo disintegration and disintegration usually begins during the early life of the cell and may be partial or complete. In this connection it is well known that the risks to life in larger organisms are much greater in infancy and early childhood. The same is evidently true in cell life. Hence, when the products of cell disintegration are abundant it indicates a feeble organization of cell tissues, and when this exists we may expect weak body tissues and hence weak organism.

Cell genesis.—It is a question as to whether there is a disease due to defective cell genesis, since reproduction is one of the strongest functions of an organism. On the other hand, excessive cell genesis is associated with many pathologic conditions.

Leucocytosis.—Leucocytosis is generally believed to result from excessive cell production. But it must be remembered that there are other factors by which leucocytosis is governed. In discussing this subject we must consider the manner in which cells are disposed of as well as their genesis. If we accept the theory that leucocytes are tissue formers, then, when a leucocyte becomes differentiated into a tissue cell, either in the process of tissue growth or in the process of tissue repair, the cell is evidently no longer in the circulation. Therefore, if this occurs a leucocyte is disposed of. On the other hand, a leucocyte may from feeble structure undergo disintegration before it become transformed into a tissue cell. In this case it is also disposed of. Hence, leucocytes may disappear from the circulation by being differentiated into tissue cells and taking upon themselves the functions of organized cells or by passing into dissolution before this is accomplished.

Furthermore, if cell genesis should be normal and from some cause the combined number of leucocytes undergoing differentiation into tissue cells and those undergoing disintegration while yet in the circulation are not equal to the number generated, an increase in the number of leucocytes existing in the circulation will evidently follow, and this is known as leucocytosis. We therefore see that theoretically it is possible to have leucocytosis without excessive cell production.

On the other hand, if the number of cells that become differentiated into tissue cells, together with those that undergo dissolution while in the circulation, are equal to the number generated, even if the number generated be in excess of normal cell genesis, yet there will be no increase in the number of leucocytes remaining in the circulation and consequently we will not have leucocytosis. We therefore see that theoretically it is impossible to have excessive cell production without having leucocytosis. Hence, the degree of leucocytosis is not so important as the other cell phenomena which accompany it, which assist in estimating the degree of cell disintegration and the differentiating power of the cells. But, when leucocytosis exists in tuberculosis we may look for one of the advanced forms of the disease, namely: *a*, Chronic suppuration; *b*, formation of lung cavity; *c*, inflammatory exudation.

Diagnosis by exclusion.—While it is true that there are a number of cell phenomena, such as poorly differentiated nuclei, leucocytosis, a marked change in the differential percentages, and many other conditions, which are present to a greater or less degree in a variety of diseased conditions, yet there are usually accompanying symptoms, or the absence of certain symptoms, which will enable one familiar with blood appearances in health and disease to make a diagnosis by the method of exclusion. Hence cell phenomena may be considered both as positive and negative evidence in forming a diagnosis, and often the negative evidence is as valuable as the positive.

Stages of tuberculosis.—In order to facilitate the study of tuberculosis I have made the following classification of the stages, and given the blood characteristics for each:

1. *The pretuberculous stage*, approaching closely to incipiency. No leucocytosis; a slight decrease in the percentage of young cells; very little or no rela-

tive increase in the percentage of phagocytes; cells of feeble differentiating power; more or less abundant debris from cell disintegration.

2. *Early incipiency*, or the stage in which the tuberculous process has not yet become general, and before there is active disintegration of the larger tissues. No, or very little, leucocytosis; moderate decrease in percentage of young cells, which decreases as the disease advances; moderate increase in percentage of phagocytes, which increases as the disease advances; accompanied by well marked evidence of cell disintegration and impaired cell differentiation.

3. *The advanced stage*, or the stage in which the disease has advanced to destructive tissue changes, *e. g.*, when there is formation of lung cavity and extensive distribution of the tuberculous infection. Slight leucocytosis; marked relative decrease in the percentage of young cells; marked relative increase in the percentage of phagocytes; abundant evidences of cell disintegration; abundant debris from cells that are going, or have already gone, into dissolution, and imperfect cell differentiation.

The fact that in tuberculosis there is more or less decrease in the percentage of young cells in the blood does not necessarily argue that there is deficient cell genesis. The explanation probably lies in the fact that cell disintegration is abundant in these cases, and that cell mortality is greatest among young cells.

At this point I wish to give a brief interpretation of the

Significance of phagocytosis.—When bacilli find the larger tissues of the body in a suitable condition for colonization, they at once begin to multiply. The first evidence, or at least one of the first evidences gained from a study of the blood, indicating that the bacilli have commenced active colonization, is a relative increase in the percentage of phagocytes, which I shall express by the term *phagocytosis.*

In using this term I do not wish to convey the meaning which is often attached to it, which relates to the function of phagocytes, but, on the other hand, I wish to express the condition of a relative increase of the number of phagocytes as compared with the other varieties of the leucocytes; in a similar manner that leucocytosis is used to signify a relative increase of the number of leucocytes as compared with the number of red cells.

One of the first principles of every organism is self-protection. Therefore, whenever there is an active colonization of bacilli in the body, we invariably find an increase in the relative percentage of phagocytes. The natural inference is that the phagocytes are interested in the defense of the organism. If bacilli are toxin producers, their toxins begin to accumulate in the body when they begin to multiply; and, on the other hand, when the toxins begin to accumulate in the body, there is invariably a marked relative increase in the percentage of phagocytes, and this consequently justifies the theory that phagocytes are antitoxin producers. Hence, when a marked phagocytosis exists, it would seem to indicate that nature was making a greater call for the antitoxins. Therefore, when there is an increase in the bacilli and their toxins in the body, the organism in self-defense calls for increase in the antitoxins; and when this occurs we invariably find a phagocytosis and often a leucocytosis.

In further proof of this interpretation, I have observed

The effects of treatment.—I have invariably foun that an improvement under any treatment in tube culosis is accompanied by:

1. A relative increase in the percentage of youn cells in the blood, which usually has decreased i proportion to the severity of the case.

2. A decrease in the phagocytosis, which exist almost always in proportion to the severity of the cas

We observe, therefore, that under a successf treatment for tuberculosis one of the effects is a d crease in the phagocytosis. And if phagocytes ar recognized as antitoxin producers, we have no alte nation except to infer that there is a decrease in th demand for antitoxins, and this further signifies th the supply of toxins has been diminished. Furthe more, if toxins are the product of the bacilli, thi directly implies that the germs are decreasing an hence the patient is improving.

Within the limits of a single paper one can do li tle more than generalize on many of the importa points which aid in forming a diagnosis and differe tiating the pathologic conditions revealed by mea of the blood. The foregoing interpretations hav been made and verified by actual experience in th study of many hundred cases of tuberculosis, bot in the progress of the disease and during convale cence, under various methods of treatment.

But notwithstanding this they are not intended dogmatic statements. They, however, express m conviction that if blood phenomena are proper studied and correctly interpreted, they will enable to approximate very closely the true state of th living organism, at a time when a diagnosis is mo valuable.

Staining methods.—One of the most importa steps in the study of pathologic blood, is the necessit of being familiar with the staining methods th bring out cell phenomena which are significant i disease. I have found it exceedingly difficult to com bine the ingredients of staining solutions in such manner as to bring out perfectly the phenomen belonging to all parts of the blood, in the same spec men. I therefore have found by experimentatio that it is of great assistance to stain two or more film of the same blood according to the methods whic bring out various sets of cell phenomena to the be advantage. By studying these in connection wit each other I ascertained that each furnished inform tion not found in the others. While making the staining experiments, I accidentally discovered th many varieties of staining could be produced upo the same blood film. By this method various po tions of the film reveal a distinct set of cell phenom ena, and by it much labor is saved.

The method which I have adopted is as follows:

TECHNIQUE OF QUADRANT STAINING.

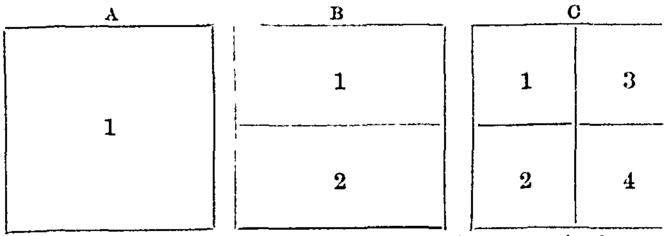

Fig. A.—1, unstained film. Fig. B.—1, unstained; 2, stained in ac stain Fig. C.—1, unstained; 2, stained in acid stain; 3, stained in ba stain; 4, stained in acid stain and counterstained in basic stain.

After properly fixing the film, the cover-glass grasped by the upper margin with a pair of force and a portion of the film lowered into an acid staining solution. It is allowed to remain in this solution a sufficient length of time to properly stain the oxyphile tissues. It is then removed from the staining solution, washed in a normal salt solution and dried between the folds of blotting paper. It is then quickly passed through a flame, with film surface uppermost, care being used to avoid overheating (Fig. B).

The cover-glass is next grasped by its left-hand margin with a pair of forceps and a portion of the film lowered into a basic staining solution. It is allowed to remain in this solution a sufficient length of time to produce proper counterstaining. It is then removed from the solution, washed and dried (Fig. C).

It is now observed that each quadrant represents a distinct set of cell phenomena and that each can be studied separately without readjusting the microscope.

First quadrant: Shows the blood in an unstained condition.

Second quadrant: Stained only with an acid stain, hence shows all oxyphile tissues.

Third quadrant: Stained only with a basic stain, hence shows all basophile tissues.

Fourth quadrant: Stained with an acid stain and counterstained with a basic stain, hence shows oxyphile, basophile and amphiphile tissues.

The claim has been made that the limits of hematology have been reached; but the more one studies the profoundly interesting phenomena observed in the blood, the more he is convinced that hematology has but commenced to reveal the truths that are possible of discovery. Why one familiar with blood work can refuse to believe the truths that are contained within the blood elements is difficult to understand. Fortunately a refusal to recognize such phenomena will not invalidate the truths which they portray.

It is quite probable that unsatisfactory blood work and the apparent lack of uniformity in the same way result from the following: 1, an imperfect or irregular technique; 2, unfamiliarity with cell tissues, and especially the phenomena of cell disintegration; and 3, absence of a systematic method of interpreting, classifying and recording phenomena.

In conclusion. When we realize that the bacillus is not the sole factor in the cause of tuberculosis; when we realize that there must be a condition of weakened resistance on the part of the tissues before the bacilli can find a congenial culture medium in which to develop, we shall have taken a long step in the right direction in the study of the disease. Also, when we realize the relation existing between leucocytes and their antitoxins on the one hand, and pathogenic organisms and their toxins on the other, we shall have advanced far toward the solution of the problem of immunity and shall have done much toward establishing the *modus operandi* of pathologic processes.

Therefore, instead of hunting for the germ of the disease, let us also search for the condition of the tissues which is known to favor its development. Instead of attempting to destroy the germ, let us also attempt to improve the condition of the body tissues and thereby render them less congenial to the germs. And if we wish to successfully accomplish this we must detect the pathologic process early in its progress. Hence, an early diagnosis made through a study of the blood element is our hope of detecting the condition of the larger tissues before they have commenced t undergo active disintegration. And if detected a this stage, proper steps may often be taken to preven the further advance of the disease. But when th condition of the tissues is discovered which fur nishes a fertile soil for the growth of bacilli, the mos persistent treatment should be instituted, accompa nied by an early change to a climate known to be les favorable to germ development.

205 Jackson Block.

THE ADVANTAGES OF CASTRATION IN THE DEFECTIVE.

Presented to the Section on State Medicine, at the Forty eighth Annual Meeting of the American Medical Association held at Philadelphia, Pa., June 1-4, 1897.

BY EVERETT FLOOD, M.D.

BALDWINSVILLE, MASS.

The conclusions presented are drawn from observ tion of twenty-six cases. None of the operations ha been reported unless more than one year has elapse and nearly all are more than 2 years old while good number are from 3 to 8 years old.

The ages of the boys vary, but are nearly all betwee 7 and 15 years. It is very easy for the critic to clai narrowness of view in any one advocating such operation as this and to offer the usual objections tradition, but it is not so easy for him to offer us an measure giving equal relief. This is not presented a panacea but simply for what it is worth and it is n a premature chance thought. The first castratio were performed with the idea of preventing masturb tion in certain cases where the habit was most co stant and the boy had no sense of shame, besides bein a confirmed epileptic and of course somewhat feebl minded.

The written consent of the parents or guardian h been obtained in each case and the operation has bee in many instances performed by a surgeon of the sta but in others by the resident officers.

It has been found in every case that the masturb tion has ceased, the boy has become fairer in con plexion, and in a few instances has taken on addition flesh. He has ceased to have foul thoughts and give expression to lasciviousness, and no longer e tices other boys to masturbate in his company as w often done before the emasculation. They have become more manageable, less inclined to quarre more capable of reasoning.

The number of spasms has diminished in every i stance, though in some cases but little, and the for and frequency of the attacks have been lessened. T mental effect on the boy is always good. If he co siders it all he looks upon himself as a specially fa ored being and a grade higher in the scale than t ordinary boy. No melancholia has so far followed t operation. The boys have become tidier in their ma ner of dress and in personal cleanliness. More con dence is reposed in them by their associates, truthfu ness has increased, parents feel safer about them. T possibility of their transmitting defects to offspring of course removed.

In some instances no particular benefit has be noticed, except the cessation of the habit, for a lon time, one or two or more years; then the boy has begu to gain and has shown steady improvement in inte lect as well as in a much reduced number of spasm Many of these cases have had all treatment stopp after the operation, and naturally some months have elapsed before they were in the usual condition of physical health. This is especially the case where the bromid habit has been broken up in conjunction with the castration, or a short time subsequent to it. The question as to whether resection of the cord would be followed by advantages equal to those coming after the removal of the glands has not been investigated.

The effect on girls has been noted in only two cases. These were subjected to operation before coming here. The results in these instances have seemed to fully justify the procedure.

ALCOVE BEDS FOR THE EPILEPTIC.

Presented to the Section on State Medicine at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, June 1-4, 1897.

BY EVERETT FLOOD, M.D.

BALDWINSVILLE, MASS.

In presenting this subject I labor under the disadvantage of advocating a theory rather than a well demonstrated fact. Caring for the epileptic in such beds as I am about to describe has, so far as I am able to learn, never been tried. An approach has been made to it in a few places, especially in the asylum at Turin, where very narrow rooms are used, but the essential features of this plan are lacking.

The method is not advanced as a plan to be followed in all cases, but as apparently well adapted to certain conditions. The idea is to make an alcove, with walls of any firm material, either plank or brick, or brick with plank or board cover, just wide enough to easily admit the fully made-up bed. The bed should run on easy rollers and possibly project a few inches out of its alcove. There may be one alcove or many, side by side. This kind of a dormitory may be constructed on the ground floor or any floor above, provided the foundations are suitably strengthened, and no very great weight is added by this kind of construction. Each alcove is to have a suitable fresh-air ingress and a proper outlet for the warmed air. There may be a door to the stall or not, according to requirements. If a door is desired, then the bed can not project beyond the sides of the alcove, but may be flush with them.

There may be a single row of alcoves, or a double row in the middle of the room, or a single row at one side, or a row on each side. The better way would seem to be to have five to ten alcoves in each row. A double row head-to-head, running through the middle of the room so that the watchman can easily walk around the whole is the plan mainly considered.

The patient gets into bed over the foot, or the bedstead may be withdrawn, the patient is tucked in by the attendant and the bed then pushed back into its alcove. Experiments have been tried with different materials, and it is shown that sounds from one alcove to another can be so deadened that no serious discomfort would be occasioned by such noises as are ordinarily heard from this class of persons, while odors from one to another are absolutely prevented and each patient is breathing pure air. If a bed becomes soiled and is withdrawn from the alcove then odors might be perceived in the adjoining places, but the bed can be quickly stripped, the bedding thrown into the shute, which is conveniently placed, and ventilated, while the patient is being attended to in the bath. To make up these beds they must be withdrawn from the alcove and the clothing adjusted. The floor and walls of each place can then be properly cleansed and the bed pushed back.

Any one of us would, I am sure, prefer a dormitory of this sort to one where there is common air space for all.

With epileptic children the clothing is kept on the bed much better than in any other way and, in fact, it would be really difficult for the patient to get himself uncovered enough to take cold.

Opposite each alcove is a ventilated space for the patient to hang his day garments. The windows in this room are above such closed spaces.

The night nurse goes around quietly looking into each alcove in the row, or in the double rows, and need not disturb any patient either with her light or by any noise she might need to make.

The cost of such construction as this would manifestly be greater than for the ordinary dormitory, for it is natural to suppose that a room especially adapted to the use of this class of patients will cost more than one designed only for the ordinary insane or demented patient. The result to be reached is a more difficult one.

Details for the construction of the remaining parts of the building have been worked out, but need not essentially differ from other asylum buildings.

RELATION OF RAILWAY COMPANIES TO STATE BOARDS OF HEALTH.

Presented to the Section on State Medicine at the Forty-eighth Annual Meeting of the American Medical Association, at Philadelphia, Pa., June 1-4, 1897.

BY G. P. CONN, A.M., M.D.

CHIEF SURGEON BOSTON AND MAINE RAILWAY, CONCORD, N. H.

In the last twenty years it has become a well-settled fact that State boards of health are primarily intended to take cognizance of the interests of health and life among the people of the State; and while it may be true that the work of a State board is to a considerable extent educational in its character, yet its scope is practically unlimited. Its observations and duties should not only pertain to the physical welfare of every citizen of a State, but business interests should receive due attention and the commercial relation of State, federal and international prosperity should never be ignored nor forgotten. Therefore, a bureau of health becomes an integral part of the executive department of a State, around which every citizen has the "inalienable right to life, liberty and the pursuit of happiness."

Such conditions represent the brightest and most potent exponents of a higher civilization, in which robust health for all classes of people is made possible. State pride is quite universal and progressive prosperity becomes a motto for every person as well as every vocation.

As an introduction to the subject I propose to briefly discuss and bring to the notice of this National Association, the above will serve to outline and emphasize the fact that hygiene, in effecting the moral and physical conditions of the inhabitants of every community, State or nation, must directly or indirectly have an influence in all business pursuits, including State, federal and international transportation.

It is a topic of much importance and, in a brief paper, can not be fully considered and therefore I can only hope to present to your notice a few of the more salient points that are ever being presented to the railroad surgeon.

Problems involving hygienic principles in railway transportation will always be promptly referred to the surgical department of the road, for the reason that only s[illegible] can deal with such questions in an intelligent [illegible] impartial manner. The surgical department of railway labor is the only section that is fitted by education and practical work to consider questions involving State, interstate and international sanitation, and in order to decide important questions regarding the life and health of the public and employes, the railway surgeon must keep in close touch with boards of health and other hygienic organizations of the country.

The public have become critical on all matters pertaining to life and health and now demand far more attention to sanitation than would have found favor a decade since and would not have been deemed necessary or expedient until within a few years.

Only a few years ago the National Association of Baggage Agents, recognizing that the public demanded more stringent rules and regulations in the transportation of dead bodies, held a consultation with experts in sanitation and formulated the following rules, which have been adopted by railroads and State boards of health throughout Pan-America:

> *Rule 1.* The transportation of bodies of persons dead of smallpox, Asiatic cholera, typhus fever or yellow fever is absolutely forbidden.
>
> *Rule 2.* The bodies of those who have died of diphtheria, anthrax, scarlet fever, puerperal fever, typhoid fever, erysipelas, measles and other contagious, infectious or communicable diseases must be wrapped in a sheet thoroughly saturated with a solution of bichlorid of mercury in the proportion of one ounce of the bichlorid to one gallon of water and incased in an air tight zinc, tin, copper or lead-lined coffin or in an air tight iron casket, hermetically sealed and all inclosed in a strong tight wooden box, or the body must be prepared for shipment by being wrapped in a sheet and disinfected by a solution of bichlorid of mercury as above and placed in a strong casket or coffin and said casket or coffin incased in a hermetically sealed (soldered) zinc, copper or tin case and all enclosed in a strong outside wooden box of material not less than one and one half inches thick.
>
> *Rule 3.* In cases of a contagious, infectious or communicable disease the body must not be accompanied by any articles which have been exposed to the infection of the disease. In addition to a permit from the board of health or proper health authorities, station agents will require an affidavit from the shipping undertaker stating how the body has been prepared and the kind of coffin or casket used, which must be in conformity with Rule 2.
>
> *Rule 4.* The bodies of persons dead of diseases that are not contagious, infectious or communicable may be received for transportation to local points in the same State when incased in a strong coffin or metallic case and inclosed in a strong wooden box, securely fastened so that it may be safely handled. But when it is proposed to transport them out of the State to an interstate point (unless the time required for transportation from the initial point to destination does not exceed eighteen hours) they must be incased in air-tight zinc, tin, copper or lead lined coffin or an air-tight iron casket or a strong coffin or casket encased in a hermetically sealed (soldered) zinc or tin case and all enclosed in a strong outside wooden box of material not less than one inch thick. In all cases the box must be provided with four iron chest handles.
>
> *Rule 5.* Every dead body must be accompanied by a person in charge who must be provided with a ticket marked "corpse," and a transit permit from the board of health or proper health authority, giving permission for the removal and showing name of deceased, age, place of death, cause of death (and if a contagious or infectious nature, the point to which it is to be shipped, medical attendant and name of undertaker.
>
> *Rule 6.* The transit permit must be made with a stub, to be retained by the person issuing it, the original permit must accompany the body to destination; and two coupons, the first coupon to be detached by the station agent at initial point and sent to the general baggage agent, the second coupon by the last train baggageman. The stub, permit and coupons must be numbered, so the one will refer to the other, and on permit will be a space for undertaker's affidavit, to be used in cases of infectious or contagious diseases as required by Rules 2 and 3.
>
> *Rule 7.* The box containing corpse must be plainly marked with paster, showing name of deceased, place of death, cause of death and point to which it is to be shipped, number of transit permit issued in connection and name of person in charge of the remains. There must also be a blank space at the bottom of the paster for station agent at the initial point to fill in the form and number of passage ticket, where from, where to and route to destination of such ticket.
>
> *Rule 8.* It is intended that no dead body shall be removed which may be the means of spreading disease; therefore, all disinterred bodies, dead of any disease or cause, will be treated as infectious and dangerous to public health and will not be accepted for transportation unless said removal has been approved by the State board of health and the consent of the health authority of the locality to which the corpse is consigned has first been obtained and the disinterred remains enclosed in a hermetically sealed (soldered) zinc, tin or copper lined coffin or box incased in hermetically sealed (soldered) zinc, tin or copper cases.

These rules were made for the protection of the public against dangerous communicable diseases. While self-interest, to a great degree, on the part of the corporations in the protection of their patrons and employes against pestilential danger probably prompted this action, none of us can doubt but that our whole country has been benefited.

I have quoted these rules as but few of the roads in the East have been careful to post these regulations, preferring to rely on the health authorities to enforce the law. More widely circulated knowledge is necessary and I take this method of bringing it to the observation of the public and the profession.

Another sanitary consideration that is always of great interest to the managers of our local and through lines of transportation, is the management of serious outbreaks of infectious and contagious disease. The advent of cholera or yellow fever, at home or abroad, disturbs commercial centers all over the world. The declaration of federal or State health authorities that smallpox is prevailing in Canada or California as an epidemic at once creates excitement and very often leads to unwarrantable interference with transportation that might be avoided if the surgical department of through lines were in touch with State and national health officers. It is true a great and decided improvement in these matters has taken place since the epidemic of smallpox in Canada in 1885. At that time the Provincial Board of Health of Ontario was the only health authority in Canada worthy of consideration; while two of the New England border States were without health authorities and entirely helpless to meet the exigencies of the occasion. Michigan and Minnesota on the west, through their most efficient boards of health, asked our federal authorities to interpose the protecting power of international quarantine.

Everyone understands that international problems require considerable time for solution and that diplomatic correspondence is oftentimes so dilatory as to be very exasperating, while every sanitarian understands that epidemics of contagious disease have no respect for geographic or municipal limitations, nor can be dispelled or discomfited by proclamation or diplomacy. The results of the appeal to the federal government in the West being far from reassuring it was determined in New Hampshire to appeal to the railroads to take the initiative and lead in public sentiment rather than follow in its wake. This seemed the more necessary by reason of municipal reports from Montreal that there was no epidemic prevailing and the fact that the Province of Quebec was without a health board that could furnish reliable information.

The epidemic was well developed in Montreal early in July, and in August the health board in New Hampshire, realizing that nothing was being done to restrict the spread of the disease, determined to warn the management of the great through lines of transportation traversing New England and the Canadas of the danger they were in of having a panic that would unnecessarily disturb transportation and might lead to a complete embargo by reason of a shotgun quarantine.

This notice was most kindly received and the managers of international transportation interests asked for information and instructions of what was necessary to protect and maintain their traffic engagements. The result of this information was a conference of railway managers and surgeons with the boards of health of New Hampshire and the Province of Ontario. This took place in the city of Montreal. A delegation from this conference met by appointment a committee of the Montreal city government. This committee, while admitting there were some cases of smallpox in the city, strenuously asserted that it was far from being an epidemic. This statement was utterly and irrefutably answered by Dr. Coverton of the Ontario Board of Health, who brought to their notice duly attested certificates of deaths by smallpox, which showed that 127 had died during the previous week and 39 the day previous. The daily records of deaths were sufficient to show the increase of the epidemic week by week and it is to the credit of the mayor and city government of Montreal that they willingly adopted a course of rigid investigation that brought into existence not only an efficient health board for the Province of Quebec, but also a Dominion board of health that is receiving commendation and support from sanitarians all over the world.

In bringing about these results and municipal reforms a great deal of animosity was engendered among the ignorant and superstitious. The anti-vaccination element in society took it upon themselves to stir up dissentions, riots prevailed and large numbers of the inhabitants boldly proclaimed that they would not submit to such rules and regulations as were deemed necessary to suppress the epidemic. The government was most ably and earnestly supported by the railroads, as a single instance will verify.

The inhabitants of a small suburban station in which was posted the rules and regulations considered necessary to protect its people and the inhabitants of other places, took occasion to send word to the division superintendent of the road running through the town that they would not submit to the rules and tore down the copies that had been posted. No further rules were sent them, but the next day every train passed that station at the rate of thirty miles an hour. The station master closed up the depot and it remained closed until the authorities of that town appointed a local health board and instructed them to support and carry out the rules and regulations that had been adopted by the managers of all railways in Canada.

A single instance of this kind was amply sufficient to bring about a reform and the people of that section were very soon educated in the elementary principles of hygiene. It is but a simple act of justice to these people to report that in a very short period they were enthusiastic supporters of every rule and regulation that gave assurance of protecting themselves and neighbors from the direful effects of a loathsome epidemic.

In less than sixty days the epidemic was stamped out and the rules and regulations abandoned. It is but fair to the management of those roads to state that with the exception of the importation of rags and paper stock there was no interruption of the running of either passenger or freight trains, neither was there any development of the disease in New England. Sanitary inspectors examined all through passengers while in transit, many were vaccinated, some were quarantined as suspicious cases and a great deal of baggage was thoroughly disinfected at division and international points.

In a paper of this kind designed for an association of medical men it is unnecessary to multiply instances of this work, neither am I disposed to flatter myself that I am imparting any new information to the members. Still it is probably quite true that a great many of the managers of our railroads have never been called on to provide for the stamping out of an epidemic of this nature, therefore if this shall be the means of bringing a work of this kind to their notice it will have served its purpose.

NATIONAL MEDICAL LEGISLATION.

Presented to the Section on State Medicine at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY JAMES T. GREELEY, M.D.

NASHUA, N. H.

I have the honor to address you on this occasion in behalf of action, already initiated, well-advanced and generally approved by you and by the profession of this and of foreign countries, because it is designed and calculated to raise the character of the profession, to exalt the capacity of those on whom the welfare of all mankind rests, to weed out or fitly qualify those empirics who are at once the bane of medicine and the terrible foes of social health and of all prosperity. The intention is necessary, is wise, practical and permanent. Its propriety is demonstrated as well by the notorious evil against which it is leveled as it is by the patent values of the purposes for which it is framed. Wherever attempted it has been crowned and laureled both by popular and professional approval. It appeals to all who desire health for themselves or others; is simple and unequivocal; criticises those only who are notoriously unworthy of tolerance and exalts modest merit as much as it condemns charlatanry, ignorance, impudence and murder. Briefly expressed, this movement approves, tends and works for a higher, a universal law, which shall raise the standard of medical education in all schools, weed out practitioners who, under whatever sounding school title, are evidently unfitted to judge the issues of life and death, and perform the duties for which they are employed, and thereby raise the practice of medicine to a level with that of other arts and sciences upon which mankind depends for its welfare and permanence, for its very being. Fortunately, I address those who are experts in all that pertains to the subject matter, and who have been deterred from action heretofore only by the enormity of the evil and apparent hopelessness of David fighting with Goliath. Their judgment is our own, their sympathies are ours. We labor only to have that judgment and their sympathy expressed and forced forward in order to place the profession in this country far to the front, and the sound health of the community attained and preserved. To secure this unquestionable benefit I address a select body of scientific men who were thoroughly trained for their duties, who have kept step with all advances, whose merits commend them to the confidence of their patients and their communities, and who are vitally concerned in the maintenance of sound doctrine and in the abrogations of charlatanry as the minister in his pulpit or the judge upon the bench.

We seek a comprehensive law to regulate the practice of medicine; a law which shall render medical quackery as dangerous as highway robbery, or more so; as disreputable as chicken stealing; which shall positively require competent knowledge as a condition *sine qua non* to a degree; and which shall be enforced by competent pains and penalties. Is there one here present who dissents from this object, who will state that it is either unnecessary or insufficient? I hear no such avowal. Were there such, even one, I would refer his opinion to the opinions of the great medical luminaries of France, of Germany, of Great Britain and all Europe, who have for years insisted that the physician's education should be *teres ac rotundus*, round and full; that it should be kept so in the light of later discoveries; that quacks should be prevented from undermining the public health and that every gain in every art should be sifted for its medicinal uses. But really, there is no scientific, no professional nor reasonable objection to our demand. The only antagonism proceeds from those men who wish to secure the honors and rewards of medical skill without learning what medicine is, without mastering anatomy, without acquiring chemistry, without such knowledge of botany even as that which stored the good wives' simples in one century and the pipsissewa and patented concoctions in another. They are animated by the same spirit which led the Ephesians to worship Diana—that of gain.

But this is not modern medicine. Modern medicine requires its pupils to thoroughly know the anatomy and make-up of man; the nature, stage and history of every disease, and to know as thoroughly the means and agencies to be employed in every event. Coke-Lyttleton said that law should be comprehended in theology, because it treated the way in which God operates. Under that rule, medicine should rate even higher, since it prescribes a cure for the evils which it alone can detect. It is the supreme and constant arbiter of human life and as such derives its knowledge from the most recondite sources, and ascertains its prescriptions from all that is old and all that is new. The most gifted can scarcely hope to compress all that is set before them in this task. What can the ignorant unlearned quack really do with one cure-all and a dozen alternatives?

I have spoken generally, but my speech is not without ample and educated reply. The officers of many boards of health, medical societies, registers of health, etc., replying to letters of inquiry concerning the evil and its remedy, have stated directly, or *inter aliis*, that "under the act just passed in this State (Massachusetts) the traveling quacks have left the State and we expect still better results." The secretary of the South Carolina Medical Examining Board says: "The State law works well; has raised the standard of the schools and will keep tramp doctors out." The secretary of the California Board of Health says: "There is a restraining influence in the law and I do not know that other States are better situated so far as quacks are concerned." The secretary of the Wisconsin Medical Society says: "The laws relating to medical practice are exceedingly lax, in fact, a dead letter, no registration being required and there being no board of examiners. I am in favor of most any kind of a compromise with the 'sectarians' in order to get a board of some sort that will help us to get a law passed." The Nevada Board of Health remarks that "the recorder is the sole judge of the genuineness of a diploma and the standing of a college, which makes the law an absolute failure."

In South Dakota "the enforcement of the law has compelled unqualified practitioners to leave the State and has compelled some medical societies to raise the standard of medical education." The Missouri Board of Health says: "The law has prevented the location of quacks and charlatans in our State; whenever a man having a diploma from a recognized school has been guilty of unprofessional conduct, we have revoked his license. We have advanced the standard of our medical societies and will soon require changes to elevate the standard of preliminary requirements." The Montana Board of Medical Examiners states: "Our law has operated to the entire satisfaction of all persons except those who have felt its weight. Our ranks are singularly free from impostors and quacks and the stranger can send for a physician assured that he will get a reputable one. The laity are in sympathy with our law and discriminate between educated and uneducated men." The State Board of Minnesota says: "The law has been very effective for nine years and has given the State the best profession of any State in the Union. We trust to improve it by increasing the preliminary education of our candidates." In Delaware "the law has been in operation a year and has given general satisfaction, although the homeopathists opposed it. Our State was a dumping ground for those who could not pass the boards of other States, and we copied the law of Pennsylvania which was very satisfactory." In New York "the general standard has been raised by the enactment of the law." North Carolina: "The law regulating the practice of medicine has been extremely beneficial in raising the standard of the profession. Our law is the oldest in the United States." The Washington (D. C.) Society "is urging Congress to legislate for its protection, and its hopes will soon be fulfilled." The Kansas Board "is making a desperate effort for the enforcement of its law all over the State, and hopes the next legislature will enact a better." In Indiana "the law is no law and the State Medical Society wants a four years' graded course and a rigid examination by a nonpartisan board. As it is the State has no law on the subject." In Idaho "the effort of the State Society to establish a State Board of Examiners was defeated by the quacks, but this winter will see such a bill passed."

Such is the law as it stands in so many States. Such are the reasons for the enactment of a general law that will protect the people from malpractice and ignorance and protect competent physicians from the rivalry of quacks and charlatans. There is every reason why such a measure should be perfected, rendered uniform, and nationalized. The end can be won only by united action, and that action can be secured only by combined and persistent labor. The desired end being approved by reason and testimony, let us formulate the legislation required, and, co-operating with every State in which the *mens sana in sano corpore* is preferred to ill health and dishonest medicine, press it unitedly and persistently. Earnest endeavors will secure universal approval and we shall see our bills of mortality reduced and the just desire of the medical profession endorsed by popular and general approval. The object is National; let the effort be as general.

MORE PHYSICIANS AND LESS LAWYERS IN CONGRESS AND LEGISLATURE.

Presented to the Section on State Medicine at the Forty-eighth Annual Meeting of the American Medical Association, at Philadelphia, Pa., June 1-4, 1897.

BY EPHRAIM CUTTER, M.D.

NEW YORK, N. Y.

The present number of physicians in the United States Congress is ten. Lawyers are 303, or about 70 per cent. (See Appendix A.)

The present is a good time to discuss this, as a department of public health in the President's Cabinet is advocated, and as the Government attends to the biologic needs of plants, cattle, hogs and sheep more than they do to the same needs of human beings.

Public health is worth more than coal, gold, houses, lands, silver or wine, although it is unlisted in the census of National wealth. There is need of physicians awaking to a realizing sense of their National rights and importance as citizens, especially in governmental bodies.

Congress and legislatures are representative bodies of the people. – Professional people alone are not truly represented. The law alone can not represent medicine. There are in the United States some 75,000 lawyers who represent some 49,000,000 of people. This is altogether beyond reason and this is said with no reproach. The same proportion of physicians and clergymen in Congress would be as bad. This was seen in the Methodist International Conference, held in the Metropolitan Opera House in New York some years ago, and in the AMERICAN MEDICAL and in the British Medical Association meetings. To me it seemed as if the clerics and medics argued as acutely, split hairs as finely and delayed business as refinedly as their legal brethren in Congress. Probably they could do no better.

When suitable persons can be found in all professions and employments in the United States they should be representatives in Congress, to avoid the "mint, anise and cummin" modes of doing delegated business.

I speak for 120,000 physicians in America and give the following reasons why they should be in Congress in larger proportion to lawyers than 10 to 303:

1. Out of fifty-six signers to the Declaration of Independence, two were physicians, *i. e.*, Benjamin Rush and Lyman Hall. Twenty were lawyers, according to the best of my information. Thus medicine was to law as one in ten. This is better than one in thirty.

2. Physicians are citizens entitled to representativeship.

3. Physicians come into more intimate contact with the people and know them more intimately than any other class of professionals.

4. They are all the time studying *evidence* more than are lawyers, because life or death is involved in their business more.

5. The emergencies physicians meet far excel those that lawyers meet. Physicians at any time are liable to be called to attend the highest officials, whose lives are of priceless value to the Nation, and at once physicians are made to fill all the functions of lawyers; to be as to evidence, counsel for, counsel against, judge and jury, promptly within a few minutes, sometimes three, and on the physician's action depend the life or death of, it may be, a president! It took the law six months to decide Guiteau's case, but a shorter time to settle that of President Garfield, the victim. Physicians must exert the same qualities of mind as lawyers, but how much more rapidly! Matters of medicine are always coming up in State affairs which physicians should decide, not lawyers. It is needless to enumerate.

6. The effort to have a department of public health in the Cabinet is evidence that the public sees that lawyers can not and ought not to administer such matters, just as it is proposed to have a cabinet department of commerce and manufactures. The fitness of things urges this action. A physician in the Cabinet would be a rarity, but we aver that he ought to be there as to State medicine.

7. The good effect of having medical examiners in place of unmedical coroners is an argument in favor of our position. Its efficiency, economy and common sense are very palpable when this plan has been adopted.

8. The effect of physicians in their own department being ruled over by lay people is embarrassing, harassing, if not paralyzing. In our late war this was done away with in some cases and with the happiest results. At any rate, in 1889, British army medical officials made the most favorable comments on this and alleged it as a superiority over English administration. A like exaltation in Congress might do as well.

9. Laws have been passed, or tried to be passed, as to medical matters, which are not complimentary to the legal fraternity, as on their faces they showed a want of acquaintance with the subject. Once there was an effort of Congress to award $100,000 for a cholera cure. It was required that all cases should be cured for one year. The lawyers forgot that this was impossible from outside causes, *i. e.*, feeble constitutions, late stages of disease, want of response to remedies and natural death rate. Sometimes the poison of disease is so powerful that the most active remedies fail. You can kick dead lions, but not some live dogs. Again, medicines act differently on different cases.

10. It is the right of physicians to be better represented in Congress because of legal medicine, and to do away with the disgraceful pitting of medical experts against each other. Commissions should be appointed as in France.

11. *The medical profession* is the *most public spirited* in deeds of charity. It gives away most to the public in unpaid labor. It has not its equal in its self-denying labors, in season or out, by day and night, summer and winter, storm and calm, danger and safety, for the worthy and unworthy, No profession works so hard to render its ministrations or existence needless. Many physicians pass their lives in going about doing good, and die poor because they

have so freely given away their ideas and substance to the poor and needy, and to the rich and well-to-do. This entitles them to places in Congress, as they prove they seek others' good.

12. The greatest physician never gave a bad character to other physicians, but pronounced repeated woes on lawyers.

13. Physicians are remarkably faithful to trusts. Surely those who trust their lives and bodies to physicians would trust them to aid in making biologic laws.

14. Our legal friends need the aid of other representatives in Congress. Although lawyers were in control of Congress for a century, still they failed to provide a proper presidential succession bill, and Hayes and Tilden were muddled with no way of relief open. None knew who was elected, politicians were at sea. Had the United States been Mexico it was said that civil war would have followed. But a Philadelphian, educated at Yale for governmental affairs, suggested that President Woolsey of Yale should head a petition that twenty-five prominent democrats and republicans should informally meet at the Fifth Avenue Hotel, New York, and consult. It was done. The course submitted by the democrats was adopted and Mr. Hayes was elected. Here President Woolsey, never a lawyer nor politician, had such an influence from his character and natural and acquired abilities, that he solved a problem for legislators. Surely they needed him!

Again, about 1815, France paid us millions of dollars for spoliation on our commerce. For nearly seventy years lawyers in Congress kept the money back, and when paid gave no interest! The unwisdom of this appears when it is said that, had these millions been paid to an individual, and he acted as our Congress did, there was not a lawyer in Congress from 1815 to 1885 but would have sued the trustees and heirs and made them pay principal and interest. If Congress had had the normal proportion of physicians, scholars, clergymen, bankers, farmers and others to help the said lawyers act as they would have made an individual trustee act, and refused for seventy years to so act themselves, then the suffering of those kept out of their lawful rights would not have been. It is doubtful if physicians would have acted so, because they are all the time relieving others' physical woes.

15. Physicians are needed in Congress to put through the department of public health in the Cabinet. It is said that Secretary Bliss was looked at unfavorably because he is a merchant. Even the charter of Greater New York provides for a non-medical man to be at the head of the board of health! The lawyers want it all.

16. More physicians are needed in Congress to see that man has his foods protected, as plant and cattle foods are protected. The adulteration of human foods and medicines is awful. When the adulterants are held to account their lawyers come to physicians, who have been most earnest in detecting such frauds, to aid in getting a light sentence. Connecticut is the only State, I am told, that has the same laws for the food of man, beast and plant. Prof. S. W. Johnson of New Haven, was the author of this common sense bill.

17. Physicians are needed in Congress to see to other causes that hinder the biologic developments of man. The family is the unit of the nation. If one is sick and feeble the other is so. Grand and noble mothers have made English and Dutch speaking nations great. None are better able to tell how to have healthy families than physicians. If States need such laws, physicians should make them. What is there more valuable to a nation than healthy human beings?

18. If physicians, lawyers and others had proper representation in Congress, more time would be spent in work and less time in words.

What a lawyer said about Congress.—We quote from "Thomas Jefferson's Works," published in 1854: "Our body was little numerous but very contentious. Day after day was wasted on the most unimportant questions. . . . I served with General Washington in the legislature of Virginia before the Revolution and during it with Dr. Franklin in Congress. I never heard either of them speak ten minutes at a time, nor to any but the main point which was to decide the question. They laid their shoulders to the great points, knowing that the little ones would follow of themselves. If the present Congress errs in too much talking how can it be otherwise in a body to which the people send 150 lawyers, whose trade is to question everything, yield nothing and talk by the hour? That 150 lawyers should do business together ought not to be expected."

19. Finally, physicians are needed in Congress to enforce all that is good in this Section of State Medicine.

As this is written, Dr. Gallinger, the only physician of the Senate. is an object lesson to illustrate this article. May 13, 1897, he reported an admirable vivisection bill. The same day he introduced a resolution for a $50,000 appropriation for Americans in Cuba who were starving. He did this much to the approval of all good and true. Physicians can not stand and let folks starve to death. But Senator Gallinger would do much more if he had his proper number of medical colleagues, in place of being all alone. The writer wishes to be understood. He does not object to lawyers in Congress, but to the excessive proportion of more than two-thirds. This is not representation, it is assumption.

Appendix A.

THE OXFORD HOTEL, WASHINGTON, D. C., Feb. 2, 1897.

My Dear Dr. Cutter:—Tough job! Plenty of doctors outside of Congress, but inside scarce as hen's teeth. So here goes. One senator is from New Hampshire. Representatives: One each from California, Kentucky, Maryland, Missouri, Ohio and two from South Carolina. . . .

Very truly yours, RALPH DUNNING.

SOME FEATURES RESPECTING THE DRAINAGE OF THE LARGER MUNICIPALITIES.

Presented to the Section on State Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY AUGUSTUS P. CLARKE, A.M., M.D.
CAMBRIDGE, MASS.

One of the chief difficulties to be overcome in the management of a large municipality is that which is encountered in providing a proper system of drainage. The method that was established at an early date consisted in the construction of small drains so as to have them open out into a ravine or natural water-course. Sometimes the large mains had their openings at the mouth of a river or directly into a harbor or bay. The objection to such a plan of laying sewers is in the tendency of the sewage matter to become deposited after a lapse of time upon the banks of the river and shores of the deeper waters. The odors given off by the deposition of such material after it has been exposed to the sun, winds and fogs are at times of the most unsavory character. Their baleful effects, however, have not always been fully recognized, especially when they have occurred in the vicinity of those towns where large establishments of commercial interests, such as pork packing, grease rendering, bone grinding, soap manufacturing and other offensive trades have been conducted. I can readily recall the bitter contest that took place some twenty-five years ago in our Boston metropolitan district over a condition of affairs not unlike that to which I have here referred. In deciding as to the dangers of allowing the continuance of those evils, in unraveling the threads of such a complication and in devising measures for their relief, the highest authority of the State government, including the municipal council, the city and the State boards of health, the supreme judicial court and the legislature, had to be invoked. The testimony offered by some of the witnesses is still worthy of comment. One leading chemist stated at the aldermanic hearing held at that time that he had made a careful investigation and found that the unpleasant smells were due to the presence of acrolein, which had been produced in some of the large business concerns and that this product had been formed by the exposing of certain fats and oils to a prolonged temperature, which was somewhat less than that of the boiling point of common water, and that the rapid tarnishing of the silver on the door plates and household utensils and the discoloring of the paint on houses and fences in the vicinity were due to the oxidizing agency of this peculiar chemic element. Another distinguished chemist, who was a witness for the offensive trades' establishment, stated that he had given the subject much attention and had found that the foul and disagreeable odors were not due to the formation of acrolein, that no such chemic compound had been generated in the processes of rendering oils and fats, and that such nce could not be evolved unless at a temperature ld be above 500 degrees, and that the raising such a degree would cause an immediate of the vessels used and a destruction of the gs in which such work would be carried on. attributed the odors to the presence of sulphurated hydrogen and sulphid of ammonium and other noxious gases that were disengaged from the sewers and from the flats of the lowlands upon which the drainage matter had been deposited. The result of the legal contest was, that after some of the principal business firms had through compromise agreed to improve the conduct of their manufacturing processes by introducing some improved machinery and by passing all foul-smelling gases through redhot tubes, the government was compelled to incur a debt for a large outlay in filling up the river bottoms, in dredging out the channel and in the construction of a number of trunk sewers for carrying the drainage matter into the deeper portions of the Charles River estuary.

Since then another great expense has been incurred for the construction of the metropolitan sewer for conducting the sewage far out into the harbor, where it could be pumped up and then so discharged as to be swept away into the sea by the ebbing of the tide. Though much has been accomplished by the completion of the undertaking, still it must be admitted that the capacity of these mains is far from being adequate for effecting the purpose which it was hoped their construction would fulfil. The surface and storm waters so necessary for diluting and attenuating the sewer contents can not be carried off by these channels, but have to be diverted in other directions for final disposition. For the more inland cities and larger town centers other methods of drainage have been attempted.

In Brockton the plan of sewerage and of the sewage disposed consists in the construction of main sewers and a reservoir into which the sewage is discharged to be stored through the night, before being lifted by means of a pumping station and carried by a force main into large filter beds raised a considerable distance above the natural water level of the ground. The filtration material consists of fine sand and gravel, the coarser portions being nearer the surface. The area in which the filtration takes place comprises about thirty acres of flat sandy land, most of which is situated in the town of Easton, and is divided into twenty-three beds. Each bed occupies a surface of about one acre. From twelve of the beds the subsoil was removed, from six the removal was only in part, in the other beds the subsoil was allowed to remain upon the land. The material, including the loam that was removed, was utilized in preparing the embankments between the filtration beds. Beneath a number of the beds a layer of clay, at the depth of upward of seven feet was found, over this was laid a series of five-inch under-drains that were connected with a fifteen-inch pipe carrying the percolating water into a brook, a small branch of the Taunton River.

The report of the board of 1895 says, substantially, that when the beds were left with level surfaces they froze in the winter to such an extent that the sewage could not be disposed upon them. When they were furrowed, however, notwithstanding that a low temperature prevailed, no trouble was encountered in this respect.

In considering the advantage which this method of sewage disposal affords to inhabitants of towns, it will be seen that some serious objections to its general adoption will become apparent. In the first place this plan of arrangement which has been denominated as the separate system, imposes the necessity of excluding all surface water and all ground water from the street sewers and the house connections. The material must therefore when disposed upon the beds, be in a more or less concentrated condition.

Another feature that should be considered in this connection lies in the general use of meters in the distribution of Brockton's water supply. It is well known that when such a device for a water service is employed many families will reduce their water for consumption and of waste to the lowest minimum, thus leaving their house drains and sewers inadequately flushed and permitting them to become the *nidi* of disease germs.

Reference to the published report of the city engineer of Brockton shows that, though the population of that place in 1895 was 33,165, the average daily flow at field during the month of January of that year was only 215,000 gallons; in February it was 100,000 gallons: and in July yet less, being only 195,000 gallons. In October, when the amount discharged had reached the highest point of the year, it was only 457,000 gallons. Examination of the report of the chemic analysis is interesting. The amount of free ammonia that was determined per 100,000 parts was 3.45, that of chlorin was 9.05. A foot-note states that the odor was offensive; the sample was collected as the sewage flowed out upon the filter beds. A chemic examination of the effluent from the underdrain at the Brockton Sewage Disposal Works, according to the report of the State Board of Health shows that the sample collected in February, 1895, when it contained a large amount of ground water, had no odor. The amount of free ammonia per 100,000 parts was reduced to .0248 and the amount of chlorin to .75. A visit which I made to the Brockton filtration beds in Easton, Feb. 6, 1897, revealed the fact that there was more or less offensive odors being exhaled from the beds for the sewage deposits. The same was observed on a visit I made there only a short time before. I was informed that much offensive or unpleasant odor had been noticed by people who were living or traveling in that vicinity.

The sewage disposal of Amherst is called the separate type system; it embraces only house drainage. The drainage matter is conducted to a settling tank about a mile from the village, thence it is carried through a pipe 520 feet in length to Fort River. Some of the sledge is removed and is used as a fertilizer on neighboring farming lands.

The sewage of the city of Worcester is exposed to chemic reaction before it is discharged into the Blackstone River. An analysis of the water shows that the pollution of the river decreases as the distance becomes greater.

An interesting fact has been brought out through the study of the relation which the cities of Lawrence and Lowell have to the Merrimack River. The water supply of Lawrence is taken from the Merrimack, which receives the drainage of a considerable portion of the State of New Hampshire; it is only nine miles above the intake of the Lawrence waterworks that the sewage of Lowell enters the river. Typhoid fever had prevailed extensively for the past years in Lowell and Lawrence during the later portions of the autumn and winter months, after the disease had nearly ceased in the towns higher up the river. Sometimes the epidemic would appear in Lowell before it reached Lawrence It should be stated that the intake of the Lowell water supply is from the Merrimack at a point somewhat above the location of the city. The large death rate occurring from typhoid fever led the board to conclude that the occurrence of the attack was owing to the disease germs that were brought down the river and that they infected the water which was furnished for the use of the inhabitants. The invasion of typhoid fever was subsequently checked by the use of sand in the construction of filtration beds which served to remove to a considerable extent the disease-producing germs.

The Board of Health further concluded that streams are insufficient for self-purification; that it is practicable to protect, to a marked degree, the community against the contamination of water that is supplied for domestic purposes, by the employment of properly constructed sand filters.

It would be interesting to c an of
purification of the sewage and t in-
age of other cities and towns of
will be sufficient to say that
regarded as merely tentative.

The plan adopted by Bro

practice that was in vogue during my early school days when the farmers in southern New England used to make large sand beds upon their fields and, into the pits that were made in them, would deposit the contents that were brought from the city privy vaults. The matter was allowed to remain until it soaked into the mass of sand or other material that was used for holding the sediment. Under or near the beds there was usually made a ditch or trench along which the vile water, after percolating through the mass, would flow and be carried into a neighboring ravine or hollow. The effect produced on our olfactories when we were passing in the vicinity gave unmistakable evidence that the "noxious effluvia" was invading our atmosphore far and wide. We also recall the fact that those districts in which it used to be the custom to deposit such masses of exuberant ordure have since become the veritable haunt of the bacillus malariæ and other disease-producing germs.

Though all must concede that the details of the present plan for the disposal of sewage have, through the advice and suggestions of the State Board of Health, been carried out in a most creditable manner, still it can but be felt that some more effective and scientific system of drainage for the rich and densely populated States should be inaugurated.

My recent visit to the Republic and City of Mexico afforded many opportunities for reflection. While there I had the privilege of visiting the drainage works of the city and of witnessing the admirable working of the desagüe and the tunnel that had been constructed, at great expense, for insuring the drainage of the City and Valley of Mexico and for conducting the sewage and the water of the lakes into the Gulf of Mexico. I will not describe in detail the plan adopted, but the method employed by the Mexican government embraces a subject that should receive the most careful consideration.

Many portions of New England and of other States adjacent to them present features for which the Mexican plan, more or less modified to suit local conditions, could no doubt with great and permanent advantage be adopted. The employment of such a method would tend to obviate many evils of our present system of drainage.

In constructing a canal after the plan I have mentioned, its bottom should have a uniform slope, its sides should be so projected as to have a proper batter, and its capacity ought to be sufficient to receive all waters that should be carried off. It should be of such a depth as not to be seriously affected by freezing during the colder months of the year.

It is far from pleasant for one to contemplate that in the future, not altogether remote, there should abound at no distant intervals all over our land and in the vicinity of the delightful prospects of the natural water courses huge piles of sand and gravel
to be continually savored wi nage of human
excrement, that vilest of all d that such a
condition must from the things be
established in the limits or re the
remc the unoffe ll be
inst ors
and to ir

ment by the government at Washington of more stringent regulations for the protection from pollution of all the navigable rivers and streams. Such protection should extend not only to the end of the navigation lines but for some distance beyond so as to include control of the important branches of such watercourses. All persons, including private individuals, persons connected with companies, corporations, towns, cities, and with the management of States should for the violation of such provisions, be subject to indictment or to the penalty of the payment of a fine.

AIR—ITS USE AND ABUSE.

Presented to the Section on State Medicine at the Forty-eighth Annual Meeting of the American Medical Association at Philadelphia, Pa., June 1-4, 1897.

BY JAMES W. COKENOWER, M.D.

SECRETARY IOWA STATE MEDICAL SOCIETY AND LECTURER ON ORTHOPEDIC SURGERY, COLLEGE OF PHYSICIANS AND SURGEONS, MEDICAL DEPARTMENT, DRAKE UNIVERSITY.
DES MOINES, IOWA.

The air we breathe is a subject of such magnitude and diversified uses, and corresponding abuses, like all other valuable elements that augment our mechanical, physical and therapeutic existence, *that the limited* time of this paper will only permit me to speak of the atmosphere in a general way, that it may be used to lengthen our longevity. It is employed in the treatment of disease in many ways and for many purposes, is used as the medium from which we get oxygen, is found in a gaseous mixture of definite composition, with a variable pressure, is used as a vehicle for other substances in a gaseous or finely divided state, and is also selected as a medium by which the temperature of the body may be readily and effectively influenced. The principles in which the dual relations of the air stands to the economy as a definite compound of certain gases, and as an atmosphere with a certain pressure, is very frequently disturbed, and this disturbance or abuse accounts for some of the most familiar phenomena of disease. Abuses in the alterations in the quality or quantity of respired air, whether from the state of the atmosphere itself, or from derangement of the complex apparatus of respiration and circulation, is the cause of some of the most serious and distressing diseases of the chest, and should prompt us to utilize all available means to change the compositions, or volume, of the air used, which is all the more practical because the supply is unlimited and composition altered at pleasure by increasing or diminishing its pressure.

We find, accordingly, that ever since the discovery of the composition of the atmosphere, frequent trials have been made of its value therapeutically, and oxygen was early recognized as its active constituent and came to be administered, as it is still, in the form of inhalation.

Within the last few years a remarkable advance has been made, on the one hand, in the physiology of respiration and the relation of the circulation to the atmospheric pressure and, on the other, in the pathology of disease of the chest.

Clearer views have been reached on the signification of various symptoms, and especially of dyspnea in its different forms and observations upon the effects of compressed and rarefied air. The modern therapeutist has availed himself of this knowledge and revived the use of air, physically altered, in the treatment of disease of the lungs, heart and other parts of the body with accuracy and successfully, and the aerotherapeutist of today has come to stay, and his methods a recognized factor in preventive medicine.

The physiologic effects of rarefied air will manifestly be different accordingly as it is admitted to the body as a whole, or only a part; and familiar examples are afforded by descent in the divingbell or ascent in a balloon; and is obviously indicated in diseases where inspiratory dyspnea is an urgent symptom, spasmodic asthma, stenosis of the air passages from anatomic causes, acute and chronic bronchitis. In threatened phthisis it is used prophylactically, and in chronic pleurisy it may prevent the collapse and retraction of the chest wall. In cardiac dilatation, due to mitral incompetence, it is useful; in general nutrition, combined with other remedies, it will relieve anemia.

We might continue indefinitely the theory of the uses and abuses of air, but enough has been said in a general way, we hope, to preface the practical utility of air as will be most beneficial to the well, the sick and, last but not least, the physician.

Investigators have been trying to discover the causes of the bad effects of defective ventilation, and while some have attributed them to excess of carbon dioxid, or deficiency of oxygen, or to both of these factors; others, and even Brown-Séquard, believed that even healthy animals exhale a volatile organic poison of the nature of an alkaloid or ptomain. Drs. Billings, Mitchell and Bergey have, in an extensive series of experiments, failed to find any trace of a volatile poison in an expired breath. However, they did find a very small amount of ammonia and combined nitrogen in human breath, and show that this is due to decomposition of organic matter in the mouth and pharnyx, but not of any peculiar volatile organic poison. They find no evidence whatever, and believe the high mortality of persons living in crowded dwellings is now known to be due in a large part to specific hereditary and acquired diseases, and that the good effects of increased ventilation are to be attributed, in a large part, to the lessened quantity of dust particles to which micro-organisms adhere. The offensive smell of public halls and places of entertainment is, *in their opinion, due to* volatile products, or decayed teeth and foul mouths, to fatty acids given off in the excretions of the skin, and to the means used for illumination. I do not believe as Drs. Brown-Séquard, Billings, and a few others, but think they have taken an extreme position on the question of the merits of rebreathed carbon dioxid. Yet, I believe if more attention was given to the character of atmosphere we breathe, and the manner in which it is taken into our lungs; if more attention was given to ventilating places of public gatherings, especially school houses and, last but not least, the sick room and private residences; if more thought was given to the noxious influences of confined air upon our physical, as well as mental economies; and if more thought was given to the therapeutic effects of the air, and less to the therapeutic benefits derived from drugs, we would succeed in many instances where we now fail, while 'tis true all either can do is to assist nature and exercise such influence on the morbid changes in tissues and organs as to restore the parts to a state compatible with systemic life.

There has recently been practically and emphatically demonstrated in Iowa the amount of *good* the combined influence of the physicians of a State can do when they pull together to mold public opinion; by the recent new medical law passed by the Iowa legislature. Realizing then the wielding power of our forces, it is our bounden duty to utilize our influence in molding public opinion in a way that all public and private buildings shall be so arranged and used, and that persistent attention will be given the subject, to the end that we may all have a pure atmosphere to live in, and our patients pure air, as well as pure drugs, to relieve them of their ills and promote their convalescence.

THE SIGNIFICANCE OF THE OCCURRENCE OF PATHOGENIC SPIRILLA IN THE WATERS OF THE DELAWARE AND SCHUYLKILL RIVERS AT PHILADELPHIA.

Presented to the Section on State Medicine at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY D. H. BERGEY, A.M., M.D.
PHILADELPHIA, PA.

As a result of a systematic study of the waters of the lower Schuylkill and Delaware along the city front during the past year, I have found over a hundred spirilla, many of which possess pathogenic properties when inoculated into the lower animals, notably pigeons and guinea pigs.

A careful study of the morphologic and biologic characters of these organisms shows that many of them are very closely allied to the group of pathogenic spirilla with which we are already familiar, the most important member of that group being the spirillum choleræ Asiaticæ, or Koch's common bacillus. The resemblance in some instances is so close that one not expert in the exact differentiation of the members of this group of organisms would be unable to detect any differences. Others deviate slightly from this type, while a considerable number show more or less marked deviation from this type.

A considerable number of these organisms are apparently identical with the vibrio Schuylkillensis isolated from the water of the lower Schuylkill last year by Dr. Abbott.[1]

The organisms were isolated from samples of water collected at different points on the two rivers along most of the city front, and from samples taken from the main and branch sewers of the city as they discharge into the rivers. Several organisms were also isolated from the water supply of the Laboratory of Hygiene, University of Pennsylvania, where the research has been conducted. These organisms were found to be most plentiful during the summer months, but were found to persist in limited numbers during the fall and winter months. About the middle of March of this year they appeared to have again increased somewhat over the numbers found during the winter months. Since they were found each month from June, 1896, to March, 1897, it is safe to assume that they are present during the entire year.

It is not necessary at present to go into details as to the general morphologic and biologic character of each of the organisms found. This will form the subject of a future report. Morphologically the different organisms varied somewhat as to the length and thickness of the rod, the degree of curvature and the tendency to form short or long spiral chains. Considerable variations were also noted as to the biologic characters of the different organisms, as, for instance, some give the characteristic indol reaction of the cholera organism, others less decidedly so, while a few failed to show any indol production. The form of the colony in gelatin plates is also variable. Some show the characteristic concentric arrangement of the cholera organism, while others deviate from it in several minor particulars. In the same manner the growth in all the different culture media varies with the different organisms; for instance, an organism may vary from the cholera group in only one particular, others in two or more particulars. Several organisms may show similarity in one or two particulars and deviate from the type in others, while other organisms show deviation from the type as to the former particulars and conformity as to the latter. When studied in detail the whole class of organisms appear to have originated from one or several ancestors and, from long continued separate existence under different conditions, they have developed this irregular form of deviation from the original types.

When all the known characters of these organisms are taken into consideration with the idea of classifying them into groups we are met with insurmountable difficulties. When grouped according to one or other of their peculiarities we are able to arrange them into several different groups, but according to which of their peculiarities is taken as the basis for classification, we find that only a limited number always fall into the same group. Indeed, our present knowledge gives us no measure by which they can be grouped systematically.

The characters which have been taken as a basis for classification are the following: Morphology, pathogenesis, indol production, form of colonies in gelatin plates, growth on blood serum, growth in litmus milk and the reaction produced on the organisms by the serum of an animal immune against one or the other of the most prominent types of the organisms.

A large number of the organisms found possess distinctly pathogenic properties for pigeons and guinea pigs. When quite small doses are inoculated the animal usually recovers and possesses a certain degree of immunity. The form of immunity conferred is closely allied, if not identical with that resulting from inoculation of the cholera organism. For this reason it is very difficult to produce absolute immunity. An animal may recover from quite large doses of a virulent spirillum and later succumb to a smaller dose. Many of the organisms were found to be but feebly pathogenic, or even non-pathogenic. The immunity conferred by one type of organism was found to be protective against large doses of another type of organism. This is in accordance with what Dr. Abbott has found with regard to the immunity conferred by the vibrio Schuylkillensis and that conferred by the vibrio Metchnikoff.

The most important point with regard to the occurrence of these organisms in the river water around Philadelphia is the fact that similar organisms have been found in the surface waters of European cities in which there had recently been an epidemic of Asiatic cholera, notably at Hamburg and Altona.[2] In this city we have not had any cases of cholera since 1873, and then only a few cases developed. The foremost bacteriologists of Europe have been inclined to the opinion that the organisms which they found in the surface waters of European cities were the remains of the true cholera organism, and that the deviations in the morphologic and biologic characters from those of the cholera organism were brought about by their prolonged existence in the water. No such explanation of the occurrence of the organisms in Philadelphia waters can be given. However, their distinctly pathogenic properties for the lower animals leads one to assume that they are not without significance. What their real significance is has not yet been determined.

The fact of the occurrence of these organisms in our surface waters at a time when there has been no outbreak of Asiatic cholera for many years, is of the utmost importance. Had these organisms been discovered subsequent to an outbreak of cholera, or at the time of a cholera scare, it is evident that their significance would have been looked upon as quite different.

It is most desirable that the surface waters of other American cities should be studied in order to ascertain whether these organisms are widely distributed. It is also desired to have careful studies made of outbreaks of diarrheal diseases in our cities, with the view of determining whether these organisms bear any causal relations to such diseases.

THE PHYSICAL AND HYGIENIC CARE OF CHILDREN.

Presented to the Section on State Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, at Philadelphia, Pa., June 1-4, 1897.

BY RANDOLPH FARIES, A.M., M.D.

DIRECTOR OF PHYSICAL EDUCATION IN THE UNIVERSITY OF PENNSYLVANIA. PHILADELPHIA.

The physical and hygienic care of children plays a most important part in the domain of medical science. At the present time more care is given to the mental development of children than to their physical education and hygienic surroundings. The cause for this seems to be due to the fact that teachers and parents know little or nothing about physiology, anatomy and hygiene. The knowledge of these subjects is very important and is especially needed by those who are interested and closely connected with pedagogy. If teachers and parents once recognized that as much, if not more, importance should be attached to the physical and hygienic welfare of children we should not see so many weak, delicate and deformed cases.

It is pitiable that the physiques of thousands of children are absolutely neglected, especially when the medical man knows perfectly well that more care in this respect would make a brighter and more active mind.

Parents and school-teachers who are ignorant of the effects of exercise on the circulation of the blood can not possibly understand the benefits of physical work in reference to improving and strengthening the constitutions of children. They will also be more ignorant of these effects unless they understand the metabolic changes brought about in the different organs and tissues of the body by physical and hygienic conditions.

The physical and hygienic care of children should not be entrusted, as it now is in the vast majority of cases, to a quack, because great harm and severe injury is very likely to be the result. It is just as essential to entrust the physical and hygienic care of a child to a specialist as it is to entrust a surgical operation to the skill of an expert surgeon. The reason so much precaution should be taken is that unless a physician thoroughly understands the effects of physical exercise he is extremely liable to do more harm than good; the result being that physical exercise is condemned when the condemnation should be attributed to the ignorance of the physician. Physical exercise properly prescribed will never be productive of anything but good results and these results are a great benefit to children, especially where the specialist is dealing with a weak, diseased or deformed patient.

It is far better, in cases where it is applicable, to prescribe physical exercise for children than to use a drug because exercise is a natural means of altering, strengthening and developing the different tissues in the body; while drugs are unnatural and employed for the most part to change pathologic to physiologic conditions. There is no safer means of strengthening the constitution of weak and delicate children than by exercise, because by this means every organ and tissue in the body receives new blood and receiving new blood is greatly benefited when auxiliary conditions of diet, sleep, ventilation, clothing, bathing and sunlight are added.

If physicians, who are consulted in reference to the physiques of delicate children, would ask themselves the question, "Am I fitted to prescribe exercise for these children," and then carefully consider the needs of such patients and send them to a specialist, much better results would be obtained. Instead of doing this, these children are sent to a gymnasium, where in the vast majority of cases the instructor knows absolutely nothing about medicine, the results after a time being overwork, disease or deformity. Many physicians have no other idea of a gymnasium than as a place where one can get "some" kind of exercise and, in addition, do not know for what purpose each piece of apparatus has been made.

There is ample reason why a physician who is not a specialist in physical culture is not capable of prescribing physical exercise for his patients. In the first place not being familiar with the different methods of prescribing exercise, he can not tell what kind of exercise to give; secondly not knowing the effects of these exercises he will be absolutely incapacitated to prescribe the proper amount; thirdly he will not be able to recognize the early symptoms of overwork when they manifest themselves; fourthly he will not know how to take and arrange anthropometric measurements; fifthly not observing his patients when they are exercising he will not know whether the proper muscles are used or what the effect upon the heart, lungs and nervous system is. These questions are of prime importance and it would *be much safer for the doctor not to prescribe exercise* for his patients and then send them to a gymnasium where the above considerations are never taken into account.

On the other hand when a physician sends these children to a specialist it is the duty of the specialist to consult with the physician by whom such patients have been sent and under no conditions should the specialist prescribe a drug of any kind because he will not understand how to prescribe for these patients so intelligently as the family physician.

Some physicians may think it is not necessary for them to possess special knowledge in prescribing physical exercise for their patients; but no one will assume for a moment that he is worthy to be called an ophthalmologist, aurist, gynecologist or surgeon unless he has made an especial study of these branches.

Physical education has had a wonderful growth in the United States in the last decade and it is a pity that few physicians and gymnastic professors (so called) recognize the vast amount of knowledge required to fit one to be a specialist in physical culture. The benefits resulting from physical exercise correctly applied are beyond measure, and the tonic effect is much better than that of drugs. The specialist in physical culture should know the effects of every kind of exercise he prescribes, *i. e.*, whether the nervous system is to be affected chiefly or whether the muscular system, the respiratory apparatus or the bony framework is the part called upon to perform the major part of the work.

In addition the hygienic surroundings of children should be most carefully observed, and everything pertaining to their improvement should be most rigidly carried out.

Diet plays no small part in this respect and the food should be most nutritious, and easily digested. Under no conditions should any food be prescribed that will in any way tax the digestive functions; and in many cases the physician must insist that the diet shall consist of nothing but milk. Physical results are ofren negative when diet is overlooked, because the gastro-intestinal canal does not perform the digestive functions properly and the patient instead of being benefited by his exercise, as he should be, finds that disease, as for example dyspepsia, is the result. Care should be exercised by the specialist in physical culture in allowing a sufficient time to elapse, in these cases, between the time food is taken and the period at which exercise begins.

If exercise be indulged in too soon after eating, great injury may result because the digestive organs will not receive an amount of blood sufficient to supply the process of digestion completely, the result being that the food is incompletely oxidized in consequence of which many diseases arise.

Bathing is also very essential in reference to the hygienic care of children. Baths of one sort or another are productive of good or bad results according to the intelligence with which they are prescribed. There are few children for whom exactly the same kind of a bath may be prescribed. Their constitutions differ so widely that it is necessary when prescribing a bath to inquire very closely into their family history and regulate the kind and temperature of the bath accordingly.

It is also important to regulate the number of baths. In most cases one bath a day will be sufficient, yet in some cases a bath every other day or twice a week will suffice. The time spent in bathing is a a factor needing the closest attention, because if these children are allowed to bathe or be bathed regardless of the length of time a chill, depression or shock, may be the result, and in consequence the nervous system may suffer greatly. The physician who makes a specialty of the physical development of children should be thoroughly posted on all matters pertaining to the different kinds of baths and to the method of prescribing them. A bath wrongly prescribed especially in the case of weak, delicate and diseased children is often as productive of injurious results as a drug given in an overdose.

Strict attention should be paid to the manner in which these children are dressed. Many parents dress their children according to the season of the year, no matter what the temperature of the weather may be, and in so doing a cold results which often leads to some bronchial or pulmonary trouble. If they would dress their children according to the temperature and not according to the season of the year these troubles would not occur.

Massage is another important topic in reference to the physical and hygienic care of children, being one of the best means the physician has for aiding him in the cure of these cases. The doctor should be so conversant with massage that he may prescribe the special kind of rubbing needed for each case. The man who is a masseur and not a doctor needs especially to be guided in rubbing these patients; yet if the physician be ignorant of the different technical ways of using massage how can he prescribe massage intelligently.

SOME OBSERVATIONS ON THE PRINCIPLES INVOLVED IN PROPHYLAXIS OR PREVENTION OF DISEASES IN GENERAL, AND OF PULMONARY TUBERCULOSIS IN PARTICULAR.

Presented to the Section on State Medicine at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY N. S. DAVIS, M.D.
CHICAGO, ILL.

Prophylaxis or preventive medicine is founded on the supposition that a large proportion of the important diseases that afflict the human race are preventable by judicious measures adopted for the purpose. Such measures must be directed toward the accomplishment of one or more of the following objects: 1. To prevent the development of the specific causes capable of inducing disease. 2. To destroy or neutralize such causes after they are developed and before they had excited active symptoms of disease. 3. To so increase the natural vital resistence of the living body that it successfully resists the action of the supposed causes of any form of disease; and 4, to interrupt contact or communication of the sick with the well. To be successful in the accomplishment of these important objects we must have reliable knowledge of the causes that produce disease, or at least the conditions and laws under which they are produced or propagated, and the vital or metabolic processes by which they are destroyed or expelled from the living body.

It has long been known that one group or class of specific causes of disease is developed only in the animal body while under the influence of the same causes. Such are the causes of the class of acute eruptive fevers, variola, varicella, scarlatina, rubeola, etc. Being evolved only in the bodies of the sick and eliminated through the various excretory processes in sufficient quantity to poison the immediate surrounding air and thereby communicate from individual to individual in confined atmosphere or by contact, they are very appropriately called contagious. Fortunately all the diseases arising from this class of causes are strictly self-limited in duration and very rarely attack the same individual more than once.

Another very important class of disease-producing poisons is developed and propagated outside of the human body, chiefly in connection with organic impurities in the air, soil, water or food, and have until recently been called infections. The important diseases arising from this class of causes are periodic and continued fevers, yellow fever, plague, cholera, and other endemic and epidemic affections, which like the preceding class are self-limited in duration, but not like them self-protective against future attacks. Their propagation does not depend so much on present contact as on the sanitary or insanitary condition of the environment.

The exact difference between a contagious and an infectious disease may be thus illustrated: Though a case of smallpox be placed in a perfectly healthy neighborhood, supplied with pure air, good water and clean soil, the patient would communicate the disease to every individual who came in close contact with him, and had not been previously protected; while if a case of erysipelas, typhoid or yellow fever or cholera be conveyed into such a neighborhood, it would not communicate the disease to a single individual in the new locality, unless the case was confined in an unventilated and unclean room until the confined air became sufficiently impregnated with the excretions to develop new infectious matter. When this has taken place, other persons from a healthy neighborhood coming into such a room and breathing its atmosphere are liable to sicken with the same disease; and many such instances have been quoted as proofs of personal contagion, when they were only foci of infection.

It is in limiting the number and destructive effects of this class of acute diseases by removing the conditions by which the soil, water or air become infectious that sanitary work has conferred its greatest benefits upon mankind. And it is in discovering the individual pathogenic bacteria and their ptomains or toxalbumins in each infection, and the laws and conditions under which they develop and multiply, that modern chemic and microscopic research has achieved its most important results in adding to the resources of the healing art.

The infections of soil, water, air and household filth have been recognized for centuries, under the names of marsh miasms, idio-miasms, and epidemic constitutions, and many of the laws by which they have been governed. But it remained for the chemists and bacteriologists of the present day to discover, isolate and propagate the active infective agents concerned in many of the diseases of this class. Very naturally, with the discovery of each pathogenic germ and ptomain came first the idea of destroying it by specific medication, and we speedily became overwhelmed with antiseptics, germicides and antitoxins with which to fight the noxious agents after they were already doing their destructive work in the blood or tissues of the living body. Experience however, is fast demonstrating that this is commencing the fight too late to achieve the most important results: for when the pathogenic germs and toxins have already pervaded the system and established their morbid process, the administration of germicides and antitoxins is found to exert but a limited control over the progress of the disease, and does nothing toward removing the insanitary conditions of the soil, the water, the air and the household want of ventilation and cleanliness.

On the contrary. so far as the sanitarians have directed their efforts intelligently against the contamination of the waters and soils of any country by excretory filth and decomposable vegetable and animal matter, and have enforced such domestic regulations as secured to the people personal and household cleanliness and free ventilation with pure air and good light, just so far have they destroyed the sources of infection, and lessened the prevalence and mortality from the whole class of infectious diseases. If any illustration of this is needed, we have only to compare England, with her sanitary officers in all her seaport cities, and even country districts, constantly waging a warfare against every species of water and soil contamination, and enforcing household cleanliness and ventilation, and year after year boldly defying the inroads of cholera, yellow fever, plague and other infectious diseases, without a recognized quarantine station on any part of her coasts, with her colonies in Asia, where almost every river, watercourse and well is so contaminated with filth that the greater part of the population may be said to eat, drink and even inhale their own excretions, and as a consequence the cholera, typhus, yellow fever and plague continue their destructive visitation from year to year.

A Haffkin with his anti-cholera vaccination may prevent a few thousand cases of cholera when an epidemic is prevailing, but he must repeat the same every year or at every return of the disease, so long as he does nothing to remove the sources of the infection. But let the soil and waters of India be purified and their future contamination guarded against with the same vigilance as they are in England, and they would have no further use for either anti-cholera vaccin or anti-plague serum.

Yet the chemists and bacteriologists are almost certain to call every toxic and pathogenic germ with which they are able to produce a disease by injection or inoculation a contagion, and the sanitarian readily falls into the same habit and calls every disease so produced *contagious*. It is on this line of investigation that the bacillus tuberculosis was discovered, and its reproduction in the sputum of the patients, and the idea of the *contagiousness* of phthisis was revived and proposed as the chief basis on which to found measures of prevention, by officially declaring the disease to be contagious and to be reported by physicians to the health authorities, as in the well known acute contagious and infectious diseases. But the wide disparity between the clinical history of the acute, self-limited, infectious diseases with the well-defined beginnings and terminations, and that of pulmonary tuberculosis or any other form of tubercular disease, with its obscure beginning, its duration through months and years, and its already diffusion in almost every township in Christendom, should cause every true sanitarian to hesitate long enough to scrutinize all sides of the subject before he decides to put smallpox, typhoid fever, cholera and tuberculosis under one and the same designation—*contagious*.

As previously remarked, one of the most important errors now common to both bacteriologists and sanitarians, is that of calling every disease *contagious* as soon as a specific germ is identified with its progress, and then directing their chief sanitary or preventive efforts toward the destruction of the germ. There is, however, a clear and very important practical distinction between the contagion that propagates acute disease wherever and whenever it comes in contact with an unprotected individual, and the specific microbes classified by M. Jaccoud (*Sem. Méd.*, January, 1897), as etiologic dualisms, because they may exist in a healthy organism without injury to the latter for an indefinite period, and become noxious only in consequence of changes undergone by the organism itself.

The bacillus tuberculosis is the most familiar example of this class. It may be found in the upper air-passage of perfectly healthy individuals, in the air of dwellings, public conveyances, hospitals and in the dust of streets in almost every part of Christendom; and yet it displays its noxious effects in producing pulmonary tuberculosis in only a limited percentage of the population in any country. The only reasonable explanation is that given by Jaccoud when he says that with this class or group of microbes "pathogensis by changes in the organism is the rule, and the traditional etiology based on heredity, congeniality, predisposition, constitution, temperament, or on somatic or cosmic influences retains all its force. These multiple and variable elements are the *true causes* of disease; the microbe is only the instrumental agent."

The truth of this statement is illustrated and confirmed by the clinical experience of the profession in all countries and through all the centuries, as could readily be shown by facts and figures, if time and space would permit. The truth is that the leucocytes and other elements of vital resistance in strictly healthy human bodies, surrounded by fairly good sanitary conditions, completely resist the influence of all the bacilli of tuberculosis to be found in the air or the dust, as the history of the Brompton Hospital for consumptives, and other hospitals in which tuberculous patients in every stage of advancement have been admitted and treated, clearly show. It is only when the natural vital resistance of the healthy living body has been impaired by persistent depressing mental influences, such as anxiety, despondency or grief, or by living in overcrowded, ill-ventilated houses on damp soils; or by insufficient food, clothing, and open air exercise; or by the use of alcoholic drinks and other anesthetic and narcotic drugs; or by prior attacks of other severe disease; or even hereditary defects of organization, that the tubercle bacillus is able to develop its destructive effects on the human subject. If this is true, the leading practicable principle of prevention is so to instruct the people that the various causes of vital impairment enumerated may be avoided.

To publicly declare tuberculosis a *contagious* disease, and require physicians to report to the health boards every case, with isolation of advanced cases, would deter large numbers from consulting a physician in the early stages of their disease, through fear of thus being reported; it would add greatly to the anxiety and despondency in families where a suspected case might exist, and would equally add to the difficulty of finding employment for such; and it would speedily lead to the erection of legal barriers in the way of changes in climate, thereby compelling the unfortunate consumptive, like the leper, to abide either in the isolation hospital or some colony on a strip of the public domain set apart for that purpose. In a word, it would be going back to repeat the sanitary treatment of consumptives practiced in Italy and Spain during the first quarter of the present century, and with very similar results.

Instead of thus directly adding to the fears, anxieties and miseries of all classes of the people, our sanitary authorities should with increased vigor, continue their work of enforcing everywhere cleanliness, house ventilation, soil drainage, pure water, wholesome food and the discontinuance of the use of all varieties of alcoholic and other anesthetic drinks, which so invariably diminish nerve sensibility and vital resistance to morbid agencies. In so doing they will accomplish vastly more in limiting the spread or prevalence of tubercular consumption than by all other agencies combined. It is to work in these directions that we owe whatever improvement in the ratio of mortality which has taken place during the present century. Indeed, if we could effectually stop the use of all varieties of alcoholic drinks, and thereby do away with their depressing and paralyzing influence on the vital processes in living matter, with the poverty and mental wretchedness that ever accompanies their habitual use, before the end of the first quarter of the incoming century the prevalence and mortality from tubercular disease would have been diminished more than one-half.

PRESENT STATUS OF INOCULATION AGAINST YELLOW FEVER.

Presented to the Section on State Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY J. McFADDEN GASTON, M.D.
ATLANTA, GA.

The attention of the medical profession has been called anew to the preventive treatment of yellow fever by the claim of Giuseppe Sanarelli to have discovered its germ.

We find in the *Medical News* (January 27) the following notice: "A cable dispatch from Rio de Janeiro to the *London Times* states that a young Italian, Giuseppe Sanarelli by name, has undoubtedly discovered the yellow fever germ. Sanarelli is the director of the Uruguayan National Institute of Experimental Hygiene, and a follower of Pasteur. He is said to have sent an account of his discovery under seal to the Academy of Medicine at Rome."

There appears also in the *Medical Record* (April 24, 1897), the following allusion to this supposed discovery: "The Rome correspondent of the *Lancet* writes that Dr. Giuseppe Sanarelli, who believes that he has discovered the bacillus of yellow fever, as well as a remedy for the disease, has embodied his researches in a monograph which has for some time been in the possession of the Academia Medica di Roma, that body being thus empowered to protect his claim to priority should that claim in the interval have been challenged. The supplementary studies by which he has sought to check the laboratory and clinical work leading up to his discovery are now completed, and the whole series, including the substance of the monograph aforesaid, will be published in three successive numbers of the *Annali dell' Instituto Pasteur*. Coincidently with the appearance of the first of these fasciculi, that is, within a few weeks' time, he will deliver before the Montevidean Society of Medicine a lecture, accompanied by illustrative preparations, in which the nature of his discovery and the successive stages by which it was arrived at will be fully set forth."

In connection with these announcements, I would ask attention to the following paragraph in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, headed "Prophylaxis of Yellow Fever in Brazil": "The disease was kept under control and stamped out in Buenos Ayres by the immediate removal of every case, as it appeared, to the floating hospital, while all the other inmates of the house were taken at the same time to the island quarantine station, where they remained until all danger was past. The house was submitted to a vigorous disinfection during the entire time of their absence, and as a final measure, all the walls were calcimined. The physician first called to the case was also quarantined in his own house for the same length of time, and the premises disinfected. By these measures the disease was restricted to a few isolated cases in the early spring. Dr. A. Simoes proclaims in the *Rev. med. chir.* of Brazil the success of inoculations with attenuated cultures of the yellow fever microbe, the micrococcus xanthogenicus discovered by Freire in 1880. Since he was authorized in 1883 by the government to administer them, 11,881 persons have been inoculated, and he states that the mortality among them has been only 0.5 per cent., while among the rest of the population it has averaged 30 per cent. The yellow fever hospital had a mortality of 78 per cent. until the inoculations were introduced, when it fell to 30 per cent. He adds that if all the strangers recently arrived and all persons exposed to contagion would have themselves inoculated epidemics would cease and there would be only a few sporadic cases, while vigorous hygienic and disinfecting measures in addition would exterminate the pest altogether. —*Cronica Medica*, October 15."

To enable those who may not have noted the progressive steps in yellow fever inoculation it is proper to state that in 1885 I drew the attention of Dr. Joseph Holt of New Orleans to the great practical importance of this matter; and as president and representative of the Louisiana State Board of Health he presented a memorial from the New Orleans Cotton Exchange to the American Public Health Association, to appoint a commission to investigate the discovery by Domingos Freire of a method for the prevention of yellow fever.

In connection with the discussion of this proposition in the *New Orleans Medical and Surgical Journal* the editor said: "It is our conviction that a few months will see Freire and his researches consigned to that lunar limbo where are laid away all things lost or forgotten here on earth."

But it appears that Freire, like Banquo's ghost, will not down and after seventeen years the work goes on successfully in Brazil, and the Argentine Republic may well profit by the latter's example instead of trusting to quarantine and disinfection alone. It is to be hoped that Sanarelli will be as successful in Uruguay as Freire and Simoes have been in Brazil.

I subsequently presented a memorial to Congress from the AMERICAN MEDICAL ASSOCIATION and it was favorably considered, but upon getting the sanction of the ASSOCIATION at its next meeting for sending two additional commissioners to assist Dr. Sternberg with his work in Brazil and Mexico, Dr. J. B. Hamilton managed to have the resolution rescinded. The same gentleman, as chairman of the Section on State Medicine at the 1890 meeting in Nashville, initiated steps to put a quietus to further investigation of the prophylactic inoculation of Freire against yellow fever, and with him and Dr. Sternberg rests the responsibility of the failure to secure its advantages in this country. It is hoped that the influence of these prominent members of the profession may yet be counted in the interest of yellow fever inoculation. Great would have been the necessity for all precautions in view of the recent outbreak of yellow fever in Cuba and of the close relations of this island with Key West and Tampa, Fla., during the present civil war for Cuba's rights, not to speak of past epidemics at Brunswick, Jacksonville and New Orleans. At the meeting of the quarantine conference in Montgomery, Ala., in 1889, I claimed that as germaine to the objects of the quarantine conference yellow fever inoculation should be accorded the place of the most radical means of prevention known and that if it accomplished anything it accomplished everything.

In an article which appeared in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION (March 22, 1890), it was urged as a fact versus fiction. Again, as late as Dec. 8, 1894, I wrote for the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION the conclusions which had been formed in September, 1894, in the International Congress of Hygiene and Demography, assembled at Buda-Pesth, Hungary. This Congress announced its belief in the discovery of Freire as follows: "It is a fact attained for science, thanks to the labors of Prof. Domingos Freire, supported by many physicians of Brazil and by observers of other countries, that a microbe (*cryptococcus xanthogenicus Freire ou bacteria de le Dantec*) is the active cause of yellow fever."

From Dr. Sternberg's instructive and interesting description of the observations made by himself and others, it is inferred that the germs or bacteria presented by Freire, Carmona, Gibier, Findlay and others are not to be regarded as identified uniformly in connection with yellow fever, so that the yellow fever bacillus has yet to be discovered. It is most probable that the views of Dr. Vaughan in regard to certain diseases being developed by ptomains after the death of bacteria in the different structures, may be the key to explain the phenomena of yellow fever. All are aware that in the case of hydatids, the chief element of disorder is their death, and hence it would seem that the most philosophic investigation, after the progressive changes in yellow fever have resulted fatally, should not detect living bacteria in the structures of the body, but that they should be sought in the fluids or secretions of the subject of yellow fever in its early stages.

Facts are stubborn things, and as in medicine we use many remedies empirically, without having any rational explanation of their *modus operandi*, we are called upon to test the prophylactic virtues of yellow fever inoculation without having a truly scientific clue to its efficacy. If it appears that inoculation in any form or with any substance, be it a bacillus or not, prevents or modifies the progress of yellow fever in human beings, we are warranted in resorting to it to secure our people against the ravages of this disease. It is claimed that such a process has been employed with satisfactory results in Rio de Janeiro by Dr. Domingos Freire, and the results have been tabulated, giving the names and location of those inoculated, *reaching above seven thousand individuals*, subject to the scrutiny of interested observers, before 1889. The deaths among all those subjected to this process *have not exceeded one to the thousand*, while the percentage of deaths among those attacked with yellow fever in the same localities has far exceeded this proportion, being one in one hundred. *Under such circumstances* we must either disprove the statistics or accept the results as conclusive. Dr. H. M. Lane, a former resident of Carthage, Mo., and now at the head of one of the largest educational institutions in Brazil, situated at San Paulo, was inoculated in 1886. He gave his report (JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Vol. VII, p. 165) in a paper on "Yellow Fever in Brazil." He was then a resident of Rio de Janeiro, Brazil, and had every opportunity for judging of the merits of inoculation. He had no great disturbance of the vital functions from inoculation, and has remained immune. The statistics of vaccination have never been questioned because the disease has never been explained by the culture of a microbe associated constantly with the disease, and recent studies presented to the consideration of the American Association of Physicians have failed to isolate the cause of variola.

The views of an editorial which appeared in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION some years ago, made this very point with reference to yellow fever inoculation and the studies that have been made by Freire and Findlay. The mosquito was shown by the latter to have inoculated the virus of yellow fever, and the more frequent number of inoculations caused a gradual attenuation of the virus. The people thus bitten were affected with yellow fever in a mild form. The idea of Freire is a similar one, but he cultivates the virus in the laboratory in such a way that he secures the prophylactic influence without the serious consequences of yellow fever.

When Jenner introduced vaccination. more than a century ago, the presumption against his process was stronger than that which exists at the present day against yellow fever inoculation, and it was necessary to determine by actual demonstration that the modified impression produced by vaccination really gave immunity from any serious effects of variola.

This running comment may serve somewhat as an introduction to the forcible words of the editor of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION (Jan. 11, 1890), and already epitomized. "And apropos of inoculations, the press of the country has again referred to the inoculations practiced at Rio de Janeiro, stating that the City Council of that city has been so favorably impressed by their ascertained value as protecting against yellow fever, that $600 a month has been voted for vaccinal establishments. To us, at a distance, it seems that the reasoning of Dr. Domingos Freire of Rio de Janeiro, Brazil, Dr. L Girerd, late of Panama, and Drs. Carlos Findlay and Delgado of Havana, is sound and based on the reasoning applied to vaccination. From a case of specific yellow fever, blood is taken from the finger and a culture is made. The attenuated culture is used for inoculating. Natural result, a mild yellow fever, or planting corn that they may get corn, to use a homely simile. Dr. L. Girerd, while in that hotbed of yellow fever, Panama, inoculated himself and produced a mild yellow fever. In December, 1886. the *Canada Medical Record* published a translation of his paper. In Havana. Cuba, Dr. Carlos Findlay repeatedly has inoculated new arrivals, with the happiest results, *i. e.*, subsequent immunity in that hotbed of yellow fever. Again, 'like produces like.' That the blood of a patient suffering from specific yellow fever must be full of its germs goes without saying. In attenuating it, the cultures made *à la* Pasteur, the gentlemen named have worked on accepted lines. They are well-known writers and investigators, as native and foreign medical literature testifies. They have fixed on certain germs or microbes which, from their constancy in their cultures, they believe to be the specific germs. Many years ago, during a limited epidemic of yellow fever at Southampton, England, Dr. Hassell of that city detected an unknown germ or entity in the blood of his patients. Ziemssen refers to it. But be that as it may, from the blood of yellow fever patients the poison of the disease is obtained.

"To repeat, time, patience and investigation will clear up the minor details; the great ones seem to be indisputable. That yellow fever is due to an entity or germ all students of yellow fever accept."

NOTE.—"At the request of Dr. Freire the government of Brazil has appointed a committee of seven prominent physicians to investigate his claims in regard to the micrococcus xanthogenicus" (JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, July 10, 1897, p. 92).

SURGERY ONE HUNDRED YEARS AGO.

AN HISTORICAL STUDY

BY DR. GEORGE FISCHER.

DEDICATED TO THE GERMAN SURGICAL ASSOCIATION.

TRANSLATED FOR THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION
BY CARL H. VON KLEIN, A.M., M.D.

XIV.—INFLAMMATION AND WOUNDS.

(Continued from page 802.)

Until within the eighteenth century opinions were divided, and it is surprising that so many surgeons instead of improving the methods of ligature, set themselves, as it were, to disparage its advantages and to discover new means of arresting the flow of blood. They charged against it that the manipulation was cumbersome, the thread insecure and that the coats of the arteries were cut and sometimes nerves were included in the ligature. from which evil consequences arose. Englishmen generally accepted the ligatures, discarded styptics entirely for the large vessels, while the flow from the smaller ones could be stopped by compression. Paré's simple method was again introduced into the English hospitals by White, then by Aikin and used with much success. Sharp, on the contrary, preferred the suture and thought that with the use of pincers the arteries could easily slip out of the ligature. All progress was checked so long as they thought it necessary to include the muscle fibers in the stricture. At that point contention began. Englishmen discarded this method entirely on account of the contraction of the muscles, of the slipping of the thread and of the cutting of the arteries (A. Monro, Gooch, White, Aikin). Bromfield always bound up the artery alone, and invented a curved and pointed hook for the purpose of drawing it up. Alanson and B. Bell likewise favored the ligature of the isolated artery; Bell furthermore considered the procedure so easy and reliable that it was foolish even to think of any other method and rash to trust the large vessels to any other means when the ligature was so simple and could be relied on so fully; he furnished the pincers with a slide for closing them. Although an advocate of ligature, Warner said he knew a few cases should be reserved for the hot iron when ligature was impossible. In France the great regard for J. L. Petit retarded the development of ligature; he allowed to the thrombus alone the power to arrest the flow of blood and close the vessel, and saw only one advantage in the ligature, that of holding back the coagulum. As the greatest advocate of direct compression, which best supports the action of the thrombus, he discarded the ligature in amputations as a cruel method. Its superiority was only gradually conceded, and its general introduction in France is especially due to Desault. With one blade of the pincers in the opening of the artery he seized and bound it with a waxed thread, which he drew only moderately tight and double knotted. (On account of the after-hemorrhage Desault bound the veins also in amputations; he introduced the two blades of the pincers into the openings of the artery and vein if they lay close together, and included them in a common ligature.)

Pouteau, who regarded the swelling of the cellular tissue as the most important factor in stopping hemorrhage, insisted that many muscle fibers be bound with the artery in order to obstruct the blood as much as possible and prevent cutting through the artery. Louis, on the contrary, who feared the quick falling away of the thread, caught as little of the tissue as possible with the artery. Deschamps proved that just this inclusion was the source of many after-hemorrhages, and with Scarpa announced the principle that for ligature the artery must be separated from all other parts, even its cellular tissue. Only with the recognition of this principle was the way opened for the general application of ligature. Those among the German surgeons who were educated in England advocated it earnestly. Richter, Heister and the two Siebolds regarded the ligature of the isolated artery as the most reliable, the safest, gentlest and most harmless means of arresting hemorrhages of the larger arteries. Richter did not fear the cutting through, if the threads were rather broad and not drawn too tight. He recommended Bromfield's hook instead of the suture, which was very popular at that time but appeared to him inconvenient. and instead of the artery pincers, which he discarded because they seized nerves and muscle fibers with the artery. (In 1753 von Brunn in Gottingen had from his investigations upon animals by binding the larger nerves, to which the severest accidents happen, enunciated the theory that in ligature of the arteries the nerves should never be bound with the artery.) He had no confidence in compression or the hot iron, but left the former to hemorrhages of the small vessels, the latter to very deep-lying blood vessels. As a modification of the ligature Scarpa advanced the method of protection to a special principle in which he laid a small strip of linen between the thread and the artery. Previously Deschamps, who objected to the insertion of foreign bodies, had come forward with a new discovery, the "Presse-artère" (1793); he took a small silver staff with a head set at right angles and doubly perforated. Between this and the thread, the end of which was passed through the two perforations and knotted in the cleft in the upper part of the staff he squeezed the artery. The fear of hemorrhages from this time on constantly diminished. The large arteries were boldly encountered. Petit, Deschamps, Ehrlich and others laid bare the injured art. cruralis and bound it. Acrel, in a case of traumatic aneurysm, successfully placed a ligature on this artery a few inches under the lig. Poupartii, and indeed Desault in aneurysm of the axillaris undertook an operation which hitherto. out of fear of a hemorrhage, had been performed only two or three times. He failed at this as he could not stop the flow of blood. and his patient died suddenly. In the year 1775 the carotis communis was for the first time bound by Warner and Else, following which Lynn, J. Hunter's assistant, in 1792 achieved the same result in a violent hemorrhage after the extirpation of the parotis. The ligature of the carotis externa was, as B. Bell relates, first performed in 1786 in a hemorrhage attending extirpation of a scirrhous tumor. Abernethy followed in 1796 with the binding up of the iliaca externa.

Next to the ligature, *compression* was the principal means for stopping hemorrhage. For this purpose the tourniquet was used, which had been invented by Morel in 1674, and which J. L. Petit had improved in 1718 by adding a screw for the drawing on of the girdle. This instrument was endlessly modified. Among the Germans Ehrlich invented a pad having a crosspiece with a handle for the purpose of compression; Brünnighausen and Hesselbach invented an iron hoop with a handle. Indirect digital compression, already known to A. Paré, found an advocate in the eighteenth century in Louis, who recommended it in amputations. Bromfield compressed the subclavia against the clavicle with the finger, and Richter in the most critical cases used the thumb in place of the tourniquet. A few German surgeons who would have nothing to do with ligature, employed compression in the form of the tampon, which was preferred by J. L. Petit to all other methods for stopping hemorrhage. Theden used a lance for this purpose. He had at first used the ligature in amputations, but never the detested ("vermaladeyeten") artery pincers—"my flesh creeps when I think of the notorious artery pincers"—because he saw contusion of the arteries and spasms of the nerves, swoons and great pain resulting from their use. He repeatedly asserted that he was able to stop every arterial hemorrhage in the extremities, even in case of the cruralis and axillaris, with the tampon, and in many violent hemorrhages he found no ligature necessary. He considered the successes of the English as of no value. When in 1745, after an amputation of the upper arm, he wished to constrict the artery, he pulled it violently back and the bleeding ceased, whereon he concluded that this drawing back action could be accomplished by the tampon, and the bleeding thus stopped. After a few successful amputations he discarded the ligature entirely, not even approving of it for after-hemorrhages. His practice was to place finely picked lint in balls about the size of a hazelnut, at the opening of every bleeding artery, and to constantly increase the size of the balls of lint so that altogether they represented the form of an inverted cone: besides this on both sides of the stump compression was exerted which increased the pressure upon the arteries. The pressure bandage, finished with a maltese cross, long narrow compresses and bandage, was moistened with arquebusade water. In case of possible transportation of the patient he had a fresh ox bladder fitted over this bandage, in order to prevent renewed hemorrhage This method of stopping hemorrhage he applied to all operations. His influence had the effect that in the Berlin schools, *needle and thread for fastening blood* vessels were discarded, as well as the artery pincers In the fifty years of rich practical experience following the first experiments, this method proved itsel so valuable that in 1795 Theden wrote: "I have performed this operation in this way when it was quit necessary. and up to this hour with the very best success." The *same opinion was held* by Schmucker who, moreover, considered tamponning by means o fine lint as altogether safer for the cruralis, and i amputations regarded it better than *ligature*, becaus of the painfulness of the latter. The two surgeons-general had become acquainted with the tampon through a city surgeon in Schweidnitz and had introduced it since 1744. Bilguer took a middle course and while for hemorrhages of the larger blood vessels he applied ligature to the isolated artery by means of pincers or a clasp, on the other hand, in the case of small blood vessels, he applied the tampon by means of a sponge and lint. With such recommendations one can readily picture the great disadvantages which resulted from the tampon in Germany, especially in military surgery. That Theden had no reason whatever to be satisfied with his results was demonstrated to him by A. F. Vogel. The latter saw five healed amputations of the upper thigh in London at one time, while Theden could only boast of two recoveries in all after this operation, which he had certainly often performed, whereupon Vogel declared that the great variance between the German and English results was because the German surgeons had discarded the ligature and arrested hemorrhages by compression and constriction of the stump.

Some surgeons applied the ligature only in case of the cruralis, and for the other arteries employed stricture and *styptics*. Indeed, the latter were so much in vogue that among the German barber-surgeons, especially in the first half of the century, almost nothing but this was talked of, aside from the hot iron. In later times also they were very much used by the best surgeons for arresting hemorrhages of the small blood vessels. Among the great number of them (vinegar, alum, vitriol, colophonium and others) the common wash sponge was very popular. Charles White arrested every hemorrhage with it, and in fifty cases of arterial injury, among them amputations of the upper thigh and of the mammæ, he required the ligature only twice. J. Bell considered it as the only rival of the ligature. A great sensation was made by the oak fungus, *agaricus*. Brossard, in 1751, had recommended this as the best remedy in amputations and for this had received a gift from the king of France. The Académie de Chirurgie had expressed a very favorable opinion of it and published the remedy after Faget and Morand had performed a successful operation with it in the presence of la Martinière. Agaricus spread quickly over European surgery and appeared to be about to supersede the ligature. Its warmest defenders were Faget and Morand, who argued as an especial feature of this "amadou" that it could be applied by any of the laity and only needed to be pressed upon the opening of the artery in order to effect a closure. The aged Moreau also preferred it because he observed that the pulse often returned after twenty-four hours, while, on the contrary, after the ligature it remained imperceptible for fourteen days. In Italy the agaricus was championed by Molinelli, and in England by Watson and Warner. The latter had, upon suggestion of the Royal Society in London, experimented with it and discovered that the agaricus arrested hemorrhage more certainly, caused less wound fever and did not retard healing so much as the ligature; it was insufficient, however, in case of injury to the large blood vessels. H. Parker opposed these indorsements (1755) and warned the surgeons; those operated upon by Faget had indeed died and Warner's patients had been so weak that even dust or flour might have stopped the flow of blood. To him the ligature was indispensable, was without danger, and the oak fungus was to be used only where ligature was impossible. Le Cat, Gooch, B. Bell and Acrel declared themselves in the same manner opposed to it. Richter denied to that agent all power of arresting hemorrhage; the arrest of the flow was caused by the simultaneous compression and not by the agaricus, for without the former the latter had no virtue and could be readily counteracted by the movements of the patient. His pupil, A. F. Vogel, held the same views. On the other hand, Theden preferred the new remedy to his hitherto used tampon with lint, and with it arrested hemorrhages of the art. mammaria, of branches of the carotis ext. and cruralis, as well as in castration. At the close of the century *cold water* for hemorrhage was introduced, especially by the Austrian surgeons Zeller and von Kern; they sought to arrest hemorrhages by cold poultices and suffusions or by a bath sponge saturated with ice-water.

Let us leave open wounds in order to contemplate the *precursors of subcutaneous surgery* a century ago. The first impetus to the subcutaneous idea had its birth in 1767 amid the clangor of music. It was J. Hunter who at a dance lacerated the tendon of Achilles and undertook a number of experiments in order to study the reuniting of the lacerated tendon. In dogs he severed the tendon of Achilles subcutaneously with a cataract needle, and in the sections observed the reuniting of the tendon taking place in the same manner as in a simple bone fracture. The principle of the exclusion of the air by means of displacement of the skin found its first practical application in the operation on the joints. Theden indeed already knew that one could open the kneecap without danger if the penetration of the air was only prevented; but when he had opened a suppurated knee joint he did nothing else than close the opening with a plaster, undoubtedly with success (1771). Bromfield for the first time, in 1773, in the extraction of a foreign body from the knee joint introduced displacement of the skin. He did this often with successful results, but did not consider it entirely without danger; indeed, B. Bell sometimes in this affection found amputation necessary. If the foreign body was located on one side of the patella, Bromfield had the skin drawn down as much as possible over the knee and tightly stretched; then he opened the skin and capsule upon the swelling, extracted the foreign body and immediately drew the skin back again toward the thigh. Compresses wet with brandy were laid upon the wound (another assistant should draw down the integuments with his hands till they form rugæ below the knee. . . Extension . . . This effected, the integuments are immediately to be drawn upward. "Chir. Observ.," I, p. 334). This displacement of the skin from above (B. Bell) or from below, in such a way that the opening in it should not correspond with the opening in the capsule, was considered by the English as the essential thing. Hunter, who had many times performed the above mentioned operation with success, laid great stress on the prevention of inflammation and the attainment of *prima intentio*, and therefore, when he closed the wound by suture, he never allowed the latter to penetrate into the hollow of the joint. In Germany Richter first grasped the subcutaneous idea and applied it (1782) in operations on the ganglia. If the sac could not be burst open a very small perforation was made before the lancet was used and the external skin was drawn aside as much as possible, so [illegible] it af[illegible]ard covere[illegible] an opening over the fragments; the patient was cured and could walk about after four months. Gypsum has been used in Europe for fractures only since the year 1814.

(To be continued.)

SOCIETY PROCEEDINGS.

National Confederation of State Medical Examining and Licensing Boards.

Abstract of the Proceedings of the seventh annual meeting, held at Hotel Walton, Philadelphia, May 31, 1897.

MORNING SESSION.

The Confederation met at 10 A.M. and was called to order by the President, Dr. WILLIAM WARREN POTTER of Buffalo, N. Y.

An address of welcome was delivered by Dr. A. H. Hulshizer of the Pennsylvania State Board of Examiners, which was responded to for the Confederation by Dr. Charles A. L. Reed of Cincinnati, Ohio.

At the conclusion of Dr. Reed's remarks, the President introduced Regent T. GUILFORD SMITH, representing the University of New York, who said, among other things, that he had been sent to attend the meeting of the Confederation with with a view to impressing the importance of preliminary education before entrance into a medical college. It was very essential to know first that the applicant is a man of good character, of good standing in the community where he lives, and furthermore, that he has a good plain English education as a minimum standard, and this in New York State was the high-school standard.

Dr. A. WALTER SUITER of Herkimer, N. Y., read his report as Secretary and Treasurer, in which he made a few references to such matters as concerned the organization as such, in the hope that the potency of its influence might thereby be increased toward the final accomplishment of the great mission which gave to it a corporate existence, namely, unification upon the broad lines of the highest standard of educational excellence of the medical profession of the country in which we live. The Confederation was now regarded by the medical public as the central head and exponent of the examining and licensing system now adopted by a large majority of the States. The report bristled with many excellent suggestions and, on motion was adopted.

The First Vice-President, Dr. CHARLES A. L. REED, then took the Chair and President POTTER delivered the annual address, selecting for his subject,

RECIPROCITY IN MEDICAL LICENSURE.

He first paid tribute to the memory of Dr. Perry H. Millard of St. Paul, then in an introduction reviewed some of the essential points of progress that have been made in State control of medical practice, and finally considered his subject.

The problem.—The most important question now to be discussed pertains to the interstate exchange of licenses and every friend of State control is interested in establishing this principle. It is one of the objects this Confederation is laboring to accomplish, but a most difficult problem for solution. A national registration bureau is desirable where legally qualified and reputable physicians may be recorded, physicians whose names appear on the register to be allowed to pass from State to State in the enjoyment of all privileges pertaining to the practice of medicine. Those chiefly agitating the question of reciprocity, however, are specialists who desire to spend profitable vacations at summer resorts and do not relish the idea of taking State examinations in the localities chosen for their holiday practice. Another class of men compelled by circumstances to change residence, is more deserving of sympathy; they take the examination uncomplainingly. Shall a State require of its own citizens a compliance with its practice laws while granting to thrifty summer specialists exemption from their operation? As the State laws forbid discrimination against the inhabitants of each there is both a legal and a moral bar to such exemptions.

Obstacles to reciprocity.—Equality of standards for admission to the study and practice of medicine is the only enduring basis on which reciprocity can be established. When the several States adopt a uniform level of preliminaries, a uniform period of collegiate training, [illegible] of methods of teaching, and finally, an [illegible] the methods of conducting State examinations and granting licenses, then reciprocity will be equitably and permanently established. It is important for the State medical examiners to come to an agreement on these several points that they may act with intelligence on a common platform. The State imposes a post-graduate examination, and none should be admitted to it who are not holders of diplomas legally obtained from registered and recognized colleges. It is understood that there must be established a uniform system of recognizing and registering medical schools in the several States.

The solution—Legislative enactments.—The remedies lie in legislative enactments. Those who most loudly and persistently demand interstate indorsement aim their criticisms at examining boards, whereas these have nothing to do with the question. The statutes in States that have established licensure prohibit interstate exchange except between such as have equality of standards. The demands of the restless and migratory doctors must be taken to the legislative halls. Meanwhile, the members of this Confederation may assist in bringing the matter to a more speedy conclusion by acquainting their legislatures with the difficulties to be overcome and by urgently recommending the adoption of such amendments to existing laws as will meet and remove the present defects. Great care must be exercised, however, in the preparation of amendments; the State laws are for the public weal, while reciprocity is only for the few. Amendments to the existing statutes should be proposed only through State medical examining boards or State medical societies; they are familiar with defects and best know the remedies needed. When legislatures can be persuaded to turn a deaf ear to all amendments that are proposed outside of official sources, it will be a happy day for the friends of State license. The object of this discussion is to divert further criticism of the delay of reciprocity into the proper channel. If legislators could be made to appreciate the fact that public health interests are involved in the question of State license, that every attempt to weaken the principle is a blow at public sanitation, and that higher standards of medical education mean better health to the people, then perhaps it would be easier to obtain and maintain the necessary laws to protect the commonwealths against that kind of ignorance, superstition or superrefinement that always lurks in the environment of quackery.

AFTERNOON SESSION.

The Confederation reassembled at 2:30 P.M. with President Potter in the chair.

Dr. EUGENE BEACH of New York, offered the following resolution, which was unanimously adopted.

Resolved, That when for any reason a license to practice medicine in any State has been revoked or suspended, the proper officer of Boards of Examiners in other States should be notified of the facts.

Prof. J. W. HOLLAND of Philadelphia, delivered an address in which, speaking as a teacher enthusiastic for higher medical education, he expressed the friendly intent of college men in the growth of the work of the medical examiners. He said: Conscientious teachers, who first looked askance, were now frankly recognizing that the State examinations had proved a stimulus to students and teachers. In fifteen States the regulations required that the medical degree should first be conferred by the college before the State Boards would consider the application for license. The examining professors must continue to meet this requirement, even while they recognize the fact that the teacher's bias in favor of his pupil tends to make a lenient examiner. The mere existence of the Confederation was significant of the unity of the medical profession and the desire for co operation in their functions. To secure uniformity among the States the prime requisite was to recognize the difference of ideals of education, not in medical qualifications so much as the preliminary branches of study. For any single licensing board to set up, as a standard preliminary to medical study, a graded curriculum requiring six or eight years and ending in a high school diploma, was to cut itself off from the satisfaction and rewards behind to attain reciprocity among the licensing boards. Was not such a standard too far in advance of the opinion of the people and the legislatures? Would not more important features of the work be imperiled by too great exaction in this particular? The task of educating each new legislature to appreciation of the needs of medical education was proving a difficult one in Michigan, Illinois and other States. Let us among ourselves prove that certain preliminary studies are *essential* to doctors everywhere and then be sure we hold fast that which is good.

Dr. WM. S. ELY of Rochester, said it was difficult for State Examining Boards to frame rules without doing injustice at some time or other to men who lacked the advantages of early education; and yet some of these men, by the possession of wonderful skill which amounts to genius, were able to make up for all the Latin and Greek and all the culture they may represent in the practical outcome of their work.

Dr. **William Bailey** of Louisville, in speaking of minimum requirements, said it was difficult to apply the principles that might be applicable to some districts, to Kentucky. He would like to see a graduate of Princeton or of Yale, after going through with his collegiate course, graduating with honor, spending four years in Jefferson Medical College, then going into one of the back counties of Kentucky, undertake to make a living. The people would not understand him. He was in sympathy with the most perfect advances that could be made in medical education, and he heartily approved of examining boards investigating medical colleges.

Dr. **N. R. Coleman** of Columbus, Ohio, read the preliminary

REPORT OF COMMITEEE ON MINIMUM STANDARD OF REQUIREMENTS FOR ADMISSION TO MEDICAL COLLEGES.

The object of this report was to prescribe such a standard as may serve as a common ground upon which all of the examining and licensing boards of the United States may unite, both with credit and protection to society. The question of practicability must take cognizance of the existing status not only of medical education, but of preliminary education in each of the several States of the Union. The present report was submitted only as one of progress, with the suggestion that the Committee on Minimum Requirements be continued for the ensuing year. It was important for the Confederation to consider the requirements already enjoined by the colleges themselves. These are as follows:

Section 1. Colleges, members of this Association, shall require of all matriculates an examination as follows: 1. An English composition in the handwriting of the applicant of not less than 200 words, said composition to include construction, punctuation and spelling. 2. Arithmetic, fundamental rules, common and decimal fractions, and ratio and proportion. 3. Algebra, through quadratics. 4. Physics, elementary (Gage). 5. Latin, an amount equal to one year's study as indicated in Harkness' Latin Reader.

Sec. 2. Graduates or matriculates of reputable colleges or high schools of the first grade, or normal schools established by State authority, or those who may have successfully passed the entrance examination provided by the statutes of the State of New York, may be exempted from the requirements enumerated in Section 1.

Sec. 3. Students conditioned in one or more of the branches enumerated as requirements for matriculation, shall have time until the beginning of the second year to make up such deficiencies; provided, however, that students who fail in any of the required branches in this second examination shall not be admitted to second course.

The foregoing extract, being Article III of the Constitution of the Association of American Medical Colleges, is to be accepted not only as the official declaration of the schools, but as the definition of the existing practice among them. It is the belief of the Committee that the colleges as a rule, particularly those of a higher class, are enforcing those regulations with a commendable degree of uniformity. Other schools are known to be lax in this particular. The supplementary evidence required by many of the licensing boards brings to the surface many examples of gross illiteracy which could not exist if the rules adopted by the College Association, as set forth above, were rigorously enforced. In the opinion of the Committee, no profession can maintain its pretension to be a learned profession, the preliminary educational requirements of which are placed upon the low plane indicated in the Constitution of the American College Association. The view is generally entertained, and the Committee is impressed that its position is a tenable one, that admission to a medical college ought to be based upon at least as high requirements as those for admission to an academic course in our universities. This view has been emphasized in the State of New York, in which, under the administration of the Regents of the University, the high school curriculum leads to the door of the academic facilities. This state of affairs, however, does not exist with any degree of uniformity in other parts of the United States. In certain of the States, education beyond the common school grade is by no means definitely organized. In others the standards are determined by municipal rather than State regulation. It is, therefore, important in designating a high school course, that the curriculum itself be specified; the general term is without specific significance. What is needed in the various States is a central body or authority which shall define and preside over the general educational interests of the State. In this way alone can the question of uniformity in educational requirements, as implied in a high school course, be determined. The Committee is of the opinion that it would not be well for the Confederation to employ the term "high school course" as definitive of the minimum requirements for admission to medical colleges without going a step further and defining just what is implied by the term "high school course."

The question of the conduct of examinations for admission, by independent examining boards, is a proposition which ought to be warmly supported by every right-thinking, honest-working medical faculty. The schools that come within the purview of such a law are relieved of all suspicions and imputations of commercialism. When such a proposition is advanced, the practical difficulty encountered in many of the States is the absence of the central authority vested with the power to conduct such examinations.

The Committee is deeply sensible of the fact that the matter of minimum requirements is one that should take precedence over all others in the general question of medical education. It is not, however, unmindful that much criticism that is effective with a legislative body, lies in the fact that a very long period of time is embraced in the academic and professional courses. The Committee commended the position taken by the Ohio State University in furnishing a course leading to the baccalaureate degree, especially adapted to the needs of medical students, and which course is covered in the period of three years. The practical character of this course can only be indicated by a specific enumeration of its studies, which we give below:

OHIO STATE UNIVERSITY. COURSE PREPARATORY TO THE STUDY OF MEDICINE.

Applicants must be at least seventeen years old, and must pass in grammar, geography, arithmetic, algebra (through quadratics), plane and solid geometry, physics, rhetoric, United States history and botany, and either astronomy, civil government or general history.

FIRST YEAR.

First Semester.	Credit hours.	*Second Semester.*	Credit hours.

Physiology: Laboratory	5	Physiology: Laboratory	5

The Committee is of the opinion that a general adoption of the example set by the Ohio State University will presently bring us to contemplate the pleasant spectacle of the general adoption of an academic rather than a high school qualification for admission to medical colleges.

The report concluded with the recommendation that, as far as it be vested in the discretion of existing examining and licensing boards, the rule be enforced that any colleges to be considered in good standing must enforce an entrance requirement embracing the studies of English grammar, English composition, rhetoric, Latin (two years), arithmetic, algebra (through quadratics), plane and solid geometry, physics (especially in heat, light, sound and electricity), botany, zoology, United States history, civil government, one modern language other than English (two years); or a high school diploma issued after four years' attendance and based upon examinations in the foregoing subjects. These subjects are embraced in the courses of a large majority of high schools which require four years of study?

DISCUSSION.

Dr. **John A. Larrabee** of Louisville, said if the standard proposed and the conclusions reached be carried out, he feared the Confederation would be deprived of many of its valuable members, and that the Association of American Medical Colleges would be depleted to a considerable extent. In regard to the qualifications being equal to degrees in colleges at their close to the baccalaureate or A.M. degree, that would leave out all but two or three of the Faculty of the University of Pennsylvania. He cited this to show that there was danger in making progress too rapidly. If we have the minimum requirements of the College Association, we had a good academic education, and what more could be desired for commencing a four years' course of study?

Dr. T. J. Happel of Trenton, Tenn., said the idea of requiring the study of astronomy was something he did not understand. He failed to see what object it could serve, unless to tell us when we might do an operation in accordance with the signs of the almanac. With reference to a high school diploma or a certificate of graduation from a high school being accepted in lieu of an examination for entrance to a medical college, his experience for the last seven years as Secretary of the State Board of Tennessee, was that a certificate from the average high school was not worth much more than a diploma of the average medical school ten years ago. Let the medical colleges examine every young man regardless of what he brings with him in the way of a diploma or certificate.

Dr. L. B. Godfrey of Camden, N. J., referred to the interchange of certificates. New Jersey had been unable to effect an interchange of certificates with New York up to this time; yet he was prepared to say, that the New Jersey standard was higher than that of New York; that the former required a more thorough medical education.

Dr. J. P. Creveling of Auburn, N. Y., endorsed the report of the Committee. The State of New York rejects from 30 to 33 per cent. of applicants, while in the examinations in New Jersey they reject from 10 to 12 per cent. He could hardly believe that New Jersey was so rigid in its examinations.

Dr. Hugh M. Taylor of Richmond, Va., believes very little good can be accomplished by enacting laws to govern medical colleges, as they could not be controlled in that way.

Dr. Augustus Korndoerfer of Philadelphia, said the great difficulty which he had observed in all discussions upon the subject of preliminary examination was that the whole idea seems to be to expect from the candidate a general literary education rather than a preliminary preparation. The whole thought of the Committee should be centered in one line, namely, how to develop a course of preliminary study to fit a medical student for the reception of the lectures he hears in a medical college, etc. If proper preliminary qualifications were required of applicants seeking admission to our medical colleges, it would better fit them for the study of medicine.

Dr. Willis F. Westmoreland of Atlanta, Ga., said if history, geography, higher mathematics, modern languages, etc., were to be incorporated in the prelimary requirements, very few men in the Confederation would be competent to conduct the examination. If a physician went before the Georgia legislature and exacted of all applicants such qualifications before entering upon the study of medicine, it would mean the wiping out of existence everything that has been accomplished in the past few years.

Dr. S. R. Dunn of Mississippi, said that while he agreed with the proposed advancement, the work should be undertaken with great care. Medical colleges could make what rules they saw fit for the admission of applicants to their schools, and the legislatures of the various States could not abolish them, and were an attempt made by State examining boards to prevent graduates or non-graduates from coming forward to be examined under stringent rules, he fears it would result in the abolishment of State examining boards.

Dr. A. K. P. Merserve of Portland, Me., said State examining boards were appointed not to attend to medical education, but to see by thorough examination and to judge of the character of the men presented whether their education has been satisfactory. These boards had the power to reject men who could not spell such words as radius and ulna, and he thinks the colleges would learn a good deal by the rejection of such men.

Dr. Wm. S. Foster of Pittsburg read a paper on

SOME PRACTICAL EXPERIENCE WITH AND THE RESULTS OF THE MEDICAL LAW OF PENNSYLVANIA.

Reference was made to the present medical law of Pennsylvania, which went into effect March 1, 1891. The act provides for three boards of seven members each, representing the State Medical Society of Pennsylvania, the homeopathic and eclectic associations. The "regular" board, representing close to six sevenths of the physicians of the State, was accorded the privilege and responsibility of taking the lead in formulating suggestions and rules for the government of the respective boards, as well as details pertaining to the examinations. The entire field of medicine is divided, for examination, into seven departments or subjects. These departments and the subjects allotted to each were then taken up *seriatim*. The essayist closed by saying that the most serious deficiency in medical graduates today was the want of sufficient preliminary education.

Dr. W. H. Sanders of Montgomery, Ala., followed with a paper entitled

THE ALABAMA SYSTEM.

The author prefaced his remarks by giving a brief explanation of the fundamental principles underlying the organization of the medical profession of the State.

The Board of Censors of the State Medical Association acts as a committee of public health for the State, and in the intervals of the sessions of the State Association exercises all of the functions conferred upon that body. This same Board also acts as a State board of medical examiners. The authorized boards of medical examiners are: 1, the Board of Censors of the State Medical Association acting as a board of examiners, and known as the State Board; 2, the boards of censors, also acting as boards of examiners, of the several counties of the State, of which there are sixty-six, known as the County Boards.

In order to practice medicine in Alabama a successful examination must be passed before some one of these authorized boards. The standard of qualifications, the subjects and methods of examination and the rules for the government of the examining boards are such as may be from time to time prescribed by the State Medical Association.

The rules at present in force may be briefly stated as follows:

1. All examinations must be in writing, and must comprise ten branches, viz., chemistry, anatomy, physiology, natural history and diagnosis of diseases, physical diagnosis, surgery, mechanism of labor, obstetric operations, hygiene and medical jurisprudence. Materia medica and the practice of medicine are intentionally omitted from this schedule in order to avoid ground upon which different sects or schools of medicine disagree.
2. The examinations are conducted by a paid supervisor, and are intended to be so conducted as to render it impossible to obtain aid. The answers to the questions are separately valued, one hundred being the maximum. For an examination to be successful, the final average must not fall below seventy-five. The time consumed in an examination is usually from six to ten days.
3. Every written examination made by a county board must be reviewed and reported upon by the State Board.
4. The county boards are not allowed to examine any applicants for license unless they hold diplomas from reputable medical colleges, the State Medical Association determining the question of reputability. Non-graduates can be examined, but they must apply to the State Board.
5. If any applicant is rejected by a county board he can not obtain a second examination by any county board until after the lapse of twelve months, but he may forthwith appeal to the State Board, which will not review the previous examination, but proceed to give an entirely new one.
6. Eclectics and homeopaths must be subjected to the same examination as "regulars." The law does not recognize sectarian differences among doctors, but erects the same standard of qualifications for all.
7. Anyone proposing to locate in a given county of the State must apply for a license either to the Board of that county, or, if he prefers, he can apply directly to the State Board. From whichever source a certificate of qualification is obtained it must be recorded in the probate office. A certificate may be transferred from one county to another.
8. All examination papers are bound and so filed as to be of easy reference.
9. Fees: To the supervisor, ten dollars; for registering in probate office, one dollar.

A very natural criticism of the Alabama law would be that it creates a multiplicity of Boards, but viewed from another standpoint this is an element of strength rather than of weakness. The great aim is the organization and discipline of the medical profession throughout the State; and the most potent of all the factors is that the County Medical Societies, through their Boards of Censors, have been made the agents of the State for the administration of the law to regulate the practice of medicine.

The following preamble and resolution was introduced and adopted:

Whereas, There exists in this country, under full authority of law, every grade of medical school, from those which equal the best in the world, to those which have not even a pretense of teaching force or equipment. And,

Whereas, Little official or authentic information exists or is available relating to the methods or standing of the low grade and fraudulent schools in such form that it can be relied upon and used by licensing bodies and courts.

Now, Therefore, be it

Resolved, That a Committee of twelve be appointed by the Chair, so distributed geographically that convenient sub-committees of three may be formed, whose duty it shall be during terms to visit, inspect and report on the equipment, teaching methods and requirements of every medical college in the United States, said report to be made to this body at its next annual meeting.

The election of officers resulted as follows: President, Dr. Wm. Warren Potter, Buffalo, N. Y.; vice-presidents, Dr. E. L. B. Godfrey, Camden, N. J., and Dr. William Bailey, Louisville, Ky.; secretary and treasurer, Dr. A. Walter Suiter, Herkimer, N. Y.

The Confederation expressed its regret, in the form of a resolution, at the early death of one of its most active, companionable and accomplished members—Dr. James Mackintosh Hays, of Greenboro, N. C.

Adjourned.

SELECTION.

Suture of Arterial Wounds.—Djemil Pasha of Constantinople, reported at the Moscow Congress two cases, one in 1894 and the other in 1896, in which he had sutured the axillary artery in the course of an operation to extirpate a recurrent cancer of the mamma. He continued: It frequently happens that surgeons are compelled to ligate a large artery, either because it has been accidentally injured in the course of an operation, or on account of some small aneurysm or an arteriovenous aneurysm, when a few stitches would have made it possible to retain the physiologic functions of the artery and save a member from occasionally inevitable gangrene. For a certain number of years, thanks to the efforts of German surgeons, suturing wounds in the veins has become almost a classic procedure, and several communications on the subject have been published. On the other hand, very few observations of sutured arterial wounds have been reported, and almost all the classic works are dumb on this very important subject.

Glück was the first to call attention to the suture of arterial wounds, when he reported to the Berlin Medical Association a case of arteriovenous aneurysm in Scarpa's triangle, in which Jage-Charteuffel had successfully sutured the femoral artery. Israel reported a second case, in which the external iliac artery had been sutured in the course of a difficult operation for perityphlitic suppuration. Heidenhain also has reported the suture of the axillary artery for carcinoma of the right mamma.

Quite recently J. B. Murphy, in an important article in the *New York Medical Record*, of January, 1897, has demonstrated that it is not only possible to suture arterial wounds, but also to resect a considerable portion of the artery. After performing the operation thirty-four times on dogs and calves, he applied it to man with complete success. He proves that simple suture is impracticable, if more than half of the circumference of the artery is torn. In such a case he advocates resection of the injured portion, followed by suture of the ends of the artery after invagination. He reports the case of a young man of 29 who had been shot in Scarpa's triangle. The hole in the artery was three-eighths of an inch in length. He resected one-half inch and sutured the central to the peripheral end with invagination.

Before having any knowledge of the observations and labors of Heidenhain, Israel and Glück, we performed the operation of suturing a lacerated artery with perfect success, more than two years ago. The first observation was the case of a woman 49 years old, Mrs. Kristik, who had recurrence of a carcinoma of the left mamma extirpated six months before. The recurring tumor was firmly attached to the vasculo-nervous bundle in the axilla, the left superior member edematous, with violent pains in the axilla and member. A second operation was decided on and performed Feb. 5, 1895. As the tumor encircled almost the entire vasculo-nervous bundle, we were obliged to proceed to an actual anatomic dissection, during which the axillary artery was injured and the hemorrhage arrested by compression with the finger. I prepared a strong silk thread to ligate the artery, but recalling an unfortunate case of gangrene of the superior member consecutive to ligature of the axillary artery for a laceration that occurred during curettement of the axilla, I abandoned the idea of ligating and determined to suture the injured part of the artery, as had been done for venous lesions. The wound, 15 mm. long, was parallel to the longitudinal axis of the artery. After having wound the blades of a couple of pairs of long, flexible curved forceps with sterilized gauze, I applied them to the artery, one above and one below. The hemostasis was complete. With a very fine curved Reverdin needle, I took five stitches, with extremely fine silk thread, close to the edge of the tear, and two more stitches in the sheath of the artery. Immediately afterward the forceps were removed and the circulation proceeded quite regularly. A few minutes' compression was sufficient to arrest the slight oozing of blood through the stitch holes. The artery pulsated strongly; the lumen was not contracted and the sutures held perfectly. The skin was sutured, leaving a small strip of sterilized gauze over the suture, to produce a slight compression, and also to enable the artery to be seized in case of ulterior hemorrhage. The patient passed a good night.

The next day the dressings were renewed and the gauze removed. The superior member was not edematous. We removed the sutures in the skin February 13, and the wound healed by first intention. The patient left the hospital the fifteenth day after the operation, completely cured. The pulsations of the axillary and even of the radial artery could be distinctly felt, but not quite so forcibly as on the other side. It is now two years and a half since the operation. I saw the woman again recently, and examination showed that the axillary artery pulsated its entire length, without trace of traumatic aneurysm.

The second observation was a recurrence of a malignant tumor of the right mamma, which had been extirpated with the whole of the pectoralis major and the corresponding axilla curetted. The patient was a woman of 48 years. The second operation occurred Aug. 15, 1896. As all the vasculo-nervous bundle was firmly adherent to the tumor, I was obliged to resect a large piece of the axillary vein and the two branches of the median nerve. In the process the artery was torn. I succeeded in arresting the hemorrhage, as above described, and discovered a lesion a centimeter in length, which I closed with four stitches, using a Reverdin needle and fine silk, as before. I could not suture the sheath in this case, as that had been destroyed in extirpating the tumor. The forceps were removed at once and as the circulation was restored the artery beat its entire length, the lumen no smaller than before. The integument was sutured with silkworm gut, and a strip of sterilized gauze left near the suture. For more than a month the superior member remained edematous and the large wound which extended to the sternum cicatrized with suppuration, but the wound in the axilla healed by first intention. Two months later I examined the patient, finding that the axillary and radial artery pulsated perfectly, but not so forcibly as on the other side. There was no traumatic aneurysm. The patient died later from generalization into both lungs; a necropsy was impossible.

The observations published by Glück, Israel and Heidenhain and Murphy's experience, demonstrate very clearly that we can not only suture a wound in an artery as we would in a vein, but also resect and suture the stumps of an artery with perfect success and without inconveniences. The technique is extremely simple, the chief point [illegible] to secure absolute hemostasis in order to determine the extent of the wound and to take the stitches properly. This can be accomplished in two ways; by applying as I did long, flexible forceps wound with sterilized gauze or rubber; one 2 cm. above and the other the same distance below the wound; or as Schede recommends for suturing a vein by applying three or four pairs of Téan's forceps close together the entire length of the wound, removing one at a time as the stitches are taken. It seems to me that the hemostasis is more complete and certain, which is an indispensable factor in the suture of arterial wounds, if the forceps are applied above and below the wound with care not to compress the coats too tight.

After having cleared the field of blood and clots the suture is made with a very delicate, slightly curved Reverdin needle, and a strong, very fine silk thread. Four stitches are sufficient for a tear 1 cm. long. If the sheath has not been destroyed it is better to suture that also with two or three stitches to insure against secondary hemorrhage. It also provides a protecting rampart in case of eventual suppuration. If there is slight oozing after the suture, compression with a gauze tampon will check it. As soon as certainty in regard to the re-establishment of the circulation is attained, every precaution must be taken to insure cicatrization by first intention. A small strip of gauze must be left at the point of the suture. It acts as a tampon on the wound and also enables the artery to be seized in case of ulterior hemorrhage, but it should be removed in twenty-four hours after the operation to allow the wound to heal by first intention.

Conclusion.—When the tear in the large arteries: carotid, subclavicular, axillary, external iliac, femoral, etc., does not extend more than 2 cm. in length or more than three eighths of the circumference, the artery must be sutured instead of ligated, as ligatures entail distressing results in the majority of cases. In longitudinal tears more than 2 cm. in length, or in tears involving more than half of the circumference, resection and suture of the stumps by invagination according to Murphy's method should be attempted before resorting to the ligature. There need be no apprehension of a traumatic aneuryism, nor of an endarthritis with thrombosis after suture of an arterial wound.

Dr. J. B. Murphy of Chicago, also demonstrated before the Congress his method of suturing blood vessels after injuries and reported five operations in which he had sutured large vessels. He rejects the principle of provisional ligatures or compression as liable to injure the intima, and secures hemostasis by placing a strong silk thread around the vessel, with which it is held tight against the finger. In all longitudinal injuries, and when continuity is retained for half of the circumference, suture of the vessel should be attempted. In other cases it should be resected for a centimeter and reunited by invagination.

Nitze of Berlin exhibited a small apparatus which he has invented for the purpose of vascular sutures. It consists of a small ivory support on which the ends of the vessel are fitted, bringing the intima into contact. A circular ligature is then applied which holds after the support is removed; tested on animals.

PRACTICAL NOTES.

Parasite of Malarial Fevers at Sierra Leone.—At a meeting of the Royal Medical and Chirurgical Society, Surgeon-Captain C. W. Duggan read a paper on the "Parasite of the Malarial Fevers at Sierra Leone." He described the symptoms of the severe malarial fevers which prevail at Sierra Leone, and gave the results of his observations on the parasite of malaria which is associated with these fevers, from which both Europeans and natives suffer. During two years' residence there he examined blood from the finger in nearly 400 cases and made special duty of fifty cases. Eleven of these cases were given in some detail. His description of the symptoms which usher in and last during the attack did not differ materially from that given by previous observers. In all the cases he found parasites in the blood from the finger. The form in which they were seen was as a very minute ring-shaped body, which in a later stage slightly enlarged, and contained a few very minute grains of pigment. A more advanced stage than this was not observed in the freshly drawn peripheral blood, with one or two exceptions. In blood taken from the surface of the brain in a fatal case he found sporulating forms. The parasite is very small, and even in the sporulating stage only takes up about a third of the red corpuscle. He counted five spores in one parasite. In the majority of cases, after some days' fever, the crescent forms of the parasite were observed, and he described various stages in its development. In one case only did he observe appearances in the parasite which could be interpreted as being possibly due to spore formation. In all the cases observed by him the tertian parasite was observed once only. This occurred in a man who had suffered from malarial fever two years previously in the West Indies. The quartan parasite was never observed. All the appearances observed were analogous to similar appearances described by Marchiafava as being found in the summer-autum fevers of Rome, and, morphologically, Surgeon-Captain Duggan was not able to detect any difference between Marchiafava's parasite and that of Sierra Leone. The crescent body in shape and size resembled that described by Laveran and the Italian authors. In dried and stained preparations of the small parasite in the finger-blood, a deeply stained nucleolar body could sometimes be observed at one point in the periphery; at other times in the center of the parasite surrounded by an unstained zone, whilst the periphery stained; sometimes two such nucleolar bodies could be observed. In the stained preparations the very fine pigment was observed on the periphery of the parasite. Dr. Thin remarked on the importance of a microscopic examination, and mentioned a case in which there was no fever, but in which by careful searching Surgeon-Captain Duggan established the diagnosis by demonstrating the malarial parasite. The fevers on the west coast of Africa were extremely fatal as compared with those in the south of Europe, and this appeared to be due to a plurality of parasites. As illustrating the danger to Europeans he mentioned an instance in which four out of five artisans died from fever almost immediately after arrival in the country. One of them was attacked on the second day, showing an unusually short period of incubation. Death occurred on the fourth day. The regular administration of quinin had a most remarkable protective effect. Dr. Mansen drew attention to the previous work of Plehn in the Cameroons, which pointed in the same direction. Microscopic examination was of the utmost importance for purposes of diagnosis, as many of the cases now known to be instances of severe malaria would formerly have been returned as cases of sunstroke. He regarded the practice in the army, of discharging men from the hospital after three days treatment, as quite inadequate, as observations showed that the parasite recurred in the blood at the end of the week. Patients should be retained in the hospital for two or three weeks, until the parasite had entirely disappeared from the blood, and if the presence of the parasites was persistent the patient should be deported from the country. He was surprised that reference was only made to the crescentic forms, as the flagellated forms could easily be produced by placing the cover glass with the film of blood in a damp cell made with a piece of wet blotting-paper. With reference to transmission of the parasite by means of mosquitoes, he pointed out that the transference was not direct, as the mosquito did not suck blood more than once. He believed that this insect was the host in which the parasite developed, and he had specimens demonstrating the presence of the flagellated form of the parasite in its stomach.

Successful Operation for Rupture of the Liver.—Moore (*Lancet*, Sept. 18 1897, p. 722) reports the case of a boy 11 years old who was kicked in the lower part of the right side of the chest by a horse. He became completely collapsed and complained of great pain in the side, and a diagnosis of rupture of the liver was made. In the course of four or five hours the abdomen had become distended, the distension continuing for about five days, without the addition of other symptoms. The bowels acted after enemata. In a short while vomiting set in and was thought to be due to pressure on the duodenum or pyloric end of the stomach. The vomited matter was fluid and of a greenish color, with specks of blood in it. The bowels were now constipated, despite the administration of enemata and purgatives. The patient suffered from pains at times which appeared to occur in paroxysms. The child was pale and thin and lay on his back with his knees drawn up. The temperature was normal and the pulse accelerated, of small volume and easily compressible. There was no abdominal distension, but there was some fulness in the hepatic region and the area of liver dulness was increased. On percussion there was marked tenderness over the liver. Hot fomentations were applied over the upper part of the abdomen and for some days the boy then presented no symptoms of importance. The bowels acted and the temperature was normal. Shortly, however, the respiration became much quickened, and on examination it was found that there was a large rounded swelling below the ribs and just to the right of the mid-line. The liver dulness became gradually increased and there was dulness over the right side of the chest almost up to the clavicle. The abdomen was somewhat distended and tympanitic. These conditions grew slightly more marked, while the area of the liver dulness became a little increased downward in the mid-axillary line. The temperature was slightly elevated. On aspiration of the chest in the sixth right interspace, twenty-four ounces of yellowish-green (bile stained) fluid were withdrawn. The fluid was subsequently found to contain bile. The chest at once became resonant in front and in the axilla. The prominence in the epigastrium became slightly less. For the next two days there was no improvement in the patient's condition. His pulse was quick, feeble and irregular and he was very pale. In the epigastrium, a little to the right of the mid-line, the rounded swelling had become very prominent and distinct. The margin of the liver could be felt about two inches above the umbilicus. The abdomen became gradually distended all over and tympanitic except in the epigastric and right hypochondriac regions. At this time he lay generally with his knees drawn up. Under chloroform, a three-inch vertical incision was now made through the rectus muscle a little to the right of the mid-line, commencing just below the ribs. The parietal peritoneum appeared to be much thickened, and on opening it a cavity containing a large quantity of dark fluid, in which clotted blood and bile could be easily distinguished, was entered. This cavity was very large, at least six inches deep, and it extended upward toward the diaphragm. The upper convex surface of the liver could be felt forming its lower boundary, and it was shut off from the general peritoneum by adhesion of the liver to the anterior abdominal wall. The cavity was washed out with warm boracic lotion and drained with strips of iodoform gauze. Four horsehair sutures were used to close the ends of the incision. The wound was covered with dry antiseptic dressings. Even after this the boy's condition was not satisfactory. The discharge from the wound quickly diminished and in a few days almost ceased. The temperature was slightly raised. There was no increase of dulness in the front of the chest or in the axillary region, but the epigastric fulness was well marked and now it appeared to fluctuate distinctly. On introducing a hypodermic needle through the wound a little dark, bile-like fluid was withdrawn. As the patient was about to be taken to the operating room he was seized with vomiting and his temperature rose to 103.6 degrees. He was anesthetized and a trocar and canula were introduced through the wound into the fluctuating swelling in the epigastrium and dark fluid bile flowed through the canula. The latter was removed and forceps introduced, opened and withdrawn in order to enlarge the opening. In this way a very large quantity, probably several pints, of fluid was evacuated. A large rubber drainage tube was introduced and left in place. From this time the patient rapidly improved. He became less pale, his breathing was easier and the fulness in the epigastrium disappeared. The discharge of bile was very profuse for about a week, but subsequently the tube was removed and the discharge ceased entirely before the patient was dismissed.

Fatal Poisoning by Arsenic in the Vagina.—Haberda (*Centralbl. für Gynäkol.*) states that a maidservant from Styria, aged 25 years, was seized with vomiting and faintness on September 20, left her situation in Vienna on September 22, and was picked up prostrate a day later and sent to a hospital. She was almost pulseless and the abdomen very tender; she pretended that she was menstruating, and no pelvic examination was made, but as she stated that she was constipated, an enema was given and a stool with bloody mucus came away. There was scarcely any pulse, and she died on September 25. At the necropsy, acute fatty degeneration and hemorrhages in solid viscera were detected and phosphorous poisoning suspected, so Haberda made a closer examination of the subject on order from the magistrates. He found icterus and hemorrhages under the skin and in the muscles. The spleen was greatly enlarged and there was recent fibrinous pelvic peritonitis. Arsenic poisoning was suspected. On searching the vagina a paper bag was found containing still a quantity of white arsenic in fine crystals. Acute inflammation of the vagina with false membrane on the labia minora and incipient sloughing of the rectal mucosa over the rectovaginal septum were detected. The labia majora were very edematous. The case was probably suicidal, as the deceased had told the hospital authorities that she was menstruating so as to throw them off their guard, though the pain must have been intense and desire for relief urgent. Haberda states that in the last century a peasant murdered three of his wives by introducing arsenic into the vagina after connection. Another wife murder was effected in the same way in 1799. In 1864 a single woman, finding herself pregnant, attempted to produce abortion by this means, but killed herself thereby. In 1890 a prostitute was murdered by a man who by force introduced a quantity of arsenic into the vagina, wrapped up in a knot of horsehair.—*British Medical Journal.*

Gastro-Jejunostomy for the Relief of Gastrectasis.—In a communication presented to the Missouri State Medical Society, Cordier (*Medical Record*, Sept. 25, 1897, p. 441) offers the following conclusions: 1, Carcinoma of the pylorus, even though removed, returns quickly and always kills; 2, pylorectomy is attended with a high mortality and is not a justifiable surgical procedure in cases of advanced carcinoma of the pylorus; 3, gastrectasis due to malignant closure of the pylorus is best treated by gastro-jejunostomy; 4, the operation advised by von Hacker best meets the indications; 5, it is not necessary to twist the bowel in making an anastomosis to prevent the bile from entering the stomach; 6, the anastomotic opening in the stomach should be at the most dependent point of the dilated organ; 7, the operation is attended with a low mortality; 8, in all cases in which marked dilatation of the stomach exists and is accompanied by emaciation, pain and invalidity the operation of gastro jejunostomy should be performed; 9, the relief of pain due to the effort of the stomach to relieve itself follows this procedure at once, the patient gains rapidly in weight and if non-malignant disease be present his former good health is restored.

Treatment of Otitis in Children.—*Before suppuration:* Soothe the pain and disinfect with 10 drops of phenicated glycerin at 1 to 20, slightly warmed in a small spoon and poured into the ear, closing the orifice with a little boricated cotton. Otherwise leave the ear in repose; no injections, etc. If this is insufficient, relief from the pain can sometimes be obtained if the tympanum is not perforated, by a ten-minute local bath of 10 drops of the following solution, as hot as it can be borne: 1 per cent. phenicated water 10 grams; cocain hydrochlorate 2 grams; neutral sulphate of atropin 0.05. If pain persists, cover the region with a hot compress of boricated water. If the base of the mastoid apophysis becomes painful to pressure and swollen, keep an ice-bag on it continuously, with the phenicated glycerin in the ear. Prescribe at the same time 2 to 3 grams of antipyrin a day, with 1 gram of sulphate of quinin; also a saline purgative, hot foot baths and naso-buccal antisepsis. If pain persists forty-eight hours, puncture the tympanum. *After suppuration:* Continue the local antiseptic treatment of nose and throat, with injections of tepid boiled water and douches of air by the nose with a Politzer syringe. The dressings, injections, douches, etc., repeated twice a day, with the auditory canal kept full of phenicated glycerin in the interim. Continue this treatment for two to three weeks, the average duration of acute suppurating otitis.—Lermoyez in *Jour. Méd. de Paris*, August 15.

Herpes and Tuberculosis.—Rouher has recently published some interesting details bearing upon a possible relation between zona and tuberculosis. It may appear under three different conditions: First, toward the end of severe pulmonary tubercle, and it is then of no special interest, but in other cases it is a very early symptom, and may, according to the writer, be looked upon as a premonitory sign. Thus he quotes cases of patients subject to herpes zoster but who did not complain of any pulmonary affection. On examination of the lungs however, early tuberculosis was discovered. In other cases forming the third group, the signs of pulmonary tubercle may be discovered after a short interval, there being no physical indication at the time of the eruption. Although zona seems to affect neuropathic or neuro-arthritic subjects, it results from the author's observations that in every case of this disease the patient should be kept under observation more particularly as concerns the lungs. The author points out the extreme importance and utility of this question should it be supported by more extensive observations.—*Journal de Médecine.*

The Aseptic Sponge in the Treatment of Metritis.—Lutaud rejects the use of caustics and the curette, except for voluminous proliferations. After slow dilatation with two or three laminaria tents of increasing sizes, requiring three to six days, and swabbing out the uterus with 1 to 10 iodoformed ether, he irrigates with hot 3 per cent. solution of sodium carbonate, first the uterus and then the cervix, and swabs again. Then he introduces a compressed sponge, in severe cases dipped for two minutes in salicylic acid, 1; alcohol, 10; water, 240. He disinfects his sponges by soaking them in a solution of naphthol or sublimate at 1 to 1000, until they are fully expanded, when they are compressed and cut as usual and kept in a well-corked bottle filled with iodoform. The sponge can be left in the uterus for six to eight hours; it produces no pain. As it expands it fills the uterine cavity completely, and squeezes the application into the remotest crevices. If indicated, he performs the Emmett operation.—*Journal de Méd. de Paris*, August 22.

Exophthalmic Goiter Treated by Resection of the Two Cervical Sympathetics.—Gerard-Marchant (*La Presse Médicale*) treated a patient with exophthalmic goiter by resection of the inferior portion of the right and left superior cervical ganglia with about two inches of the nerves; an improvement in the eye condition was noticeable almost immediately, and this increased until the exophthalmos was very slight indeed. The pulse decreased from 80 to 100 to a constant rate of 80. In the same number of this journal, Chauffard mentions a similar case occurring in a man. Quenu performed a bilateral operation as above described. The immediate results were scarcely noticeable. Two and one-half months later an attack of tachycardia came on, and the patient was given a bottle of digitalis with instructions regarding its use. He took nearly the whole contents of the bottle and died some hours later of acute digitalism. However, he lived long enough to demonstrate the failure of the operation.—*Medical News*, September 25.

Improvement in Sounds, etc.—One of the little annoyances that bother the busy practitioner is the difficulty of screwing a metal sound into its conductor at the bedside; the screw never catches in the thread at first. Gourdet has obviated this difficulty by having his sounds, etc., made with a smooth continuation of the screw part, extending about the same distance below, the diameter just large enough to allow its being slipped into and beyond the female screw in the conductor into a corresponding hole below, bringing the two long axes of the sound and conductor into line at the first contact.—*Presse Médicale*, July 28.

Treatment of Anal Pruritus.—Make frequent lavages with chamomile water, boricated or combined with saponined coal tar; afterward apply a soothing salve of vaselin and zinc oxid, and powder profusely with the following powder: pulverized camphor, 2 grams: zinc oxid, 30 grams; bismuth subnitrate, 30 grams; talc, 40 grams, holding the powder in place with absorbent cotton. When the parts are less irritated, paint every other day with a 25 per cent. solution of nitrate of silver. A suppository of cocoa butter, cocain and belladonna can also be inserted every night.—L. Brocq, in *Jour. de Méd. de Paris*, August 8.

Flexion Cure for Sciatica.—P. Bonuzzi reports ten absolute cures in fourteen cases of obstinate sciatica, treated by his method of forced anterior flexion of the body preceded and followed by massage at intervals of one to five days. Improvement commences with five or six, and the longest time required was twenty *séances*. When all other means have failed he recommends this treatment, which is merely the bloodless stretching of the nerves involved in the neuralgia. He never uses chloroform, but advises it in extremely painful cases. Only one case resisted the treatment completely.—*Gazz. d. O. e d. C.*, August 22.

Oil Injected into the Vasa Deferentia, Resected for Prostatic Troubles.—The patient was a man 77 years old whose prostate was so hypertrophied that each lobe felt as large as a hen's egg by rectal palpation; for two years he had had difficulty in urinating. After bilateral section of the vasa Jaboulay continued by injecting iodoformed oil inserted without pressure into the peripheral and central end of each canal, ligating the four ends to prevent the escape of the fluid. A few days afterward the patient was able to urinate freely and the hypertrophy of the prostate had entirely disappeared.—*Semaine Méd.*, August 4.

Suppositories for Dysentery in Children.—Neutral sulphate of aluminum and potassium, 20 centigrams; lead acetate, .05 centigrams; cocoa butter, 20 grams; melted wax, 20 drops; to make 10 suppositories. Insert one every three to four hours. Especially beneficial after intestinal irrigation with a 1 per cent. solution of tannin, to which a few drops of Sydenham's laudanum are added.—T. Guida, *Semaine Méd.*, August 4.

The X-Ray in Food Inspection.—It has been found that with a little experience adulterations in tea, coffee, flour, beans, *etc.*, and old and wormy nuts can be readily detected with the X-ray.—*Therap. Woch.*, August 22.

Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance	$5.00
Foreign Postage	1.75
Single Copies	10 Cents.

In requesting change of address, give *old* as well as new location.
Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the *Editor*, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, OCTOBER 23, 1897.

THE VISCERAL CHANGES IN EXTENSIVE SUPERFICIAL BURNS.

Many hypotheses have been brought forward to account for the constitutional symptoms following extensive superficial burns. Thus almost every writer on the subject advances a theory of his own as to their general pathology. Recently C. R. BARDEEN[1] reviews these various theories and finds it possible to group them somewhat like this: 1. Theories that involve the idea that burns are due to loss of normal cutaneous activity, especially as regards, *a*, the respiratory function; *b*, the perspiration; *c*, the heat regulating functions, and *d*, the protective functions. 2. Theories based on the idea that death is due to excitation of the nervous system, such as shock or reflex exhaustion and loss of vascular forces. 3. Theories urging death as due to cardiac paralysis caused by cooled blood, overheated blood or poisonous substances in the blood. 4. Theories that explain death as due to alterations in the circulation, because the blood is "driven in" by the heat (earlier writers), or because it accumulates in the peripheral vessels or on account of thrombosis. 5. Theories that claim the fatal result is due to alterations in the blood itself due to destruction or loss of function of red corpuscles. 6. Theories that attribute death to the presence of poisonous substances in the blood produced directly or indirectly in the burned areas.

"The clinical picture presented after extensive cutaneous burns is a striking one. The unfortunate victim, after a brief period of excitement and agony caused by the extreme pain, soon loses the power of much movement or resistance. The intelligence, at first fairly clear in spite of the great shock, gradually becomes beclouded. At times there may be delirium and cramps. The skin in the burned areas usually rapidly undergoes premature swelling. The pulse becomes very weak and rapid. . . . The respiration becomes rapid, irregular and shallow. The temperature, at first rising quickly above the normal, soon becomes subnormal in the rapidly fatal cases. There may be vomiting and diarrhea. The urine often shows traces of hemoglobin and albumin."

Now, after death, especially if this occurs soon after the burn, there may be no striking internal pathologic lesions, and irregularly distributed passive hyperemia of varying degree and small extravasations are often observed and cloudy swelling is usual. Occasionally gastric and duodenal ulcers are present. The blood shows well marked alterations, among which may be mentioned some rise of specific gravity, structural and also functional changes in the red corpuscles and a marked polymorphonuclear leucocytosis. Fragments of red blood corpuscles and blood pigment are found in the spleen, bone-marrow and lymphatic glands; thrombosis occurs occasionally in the capillaries and veins of some of the internal organs, and the majority of current text-books attribute death after burns to thrombosis.

Recently the view has become prominent that after burns toxic substances enter the circulation and cause the symptoms above quoted. This toxemia might be caused in various ways, but definite proof of the existence of toxic substances has not yet been offered. We know that in many infections and intoxications, spontaneous and experimental, certain quite typical lesions in the form of foci of necrosis may develop. BARDEEN's demonstration[2] of similar areas of cell death in the lymph follicles after burns is therefore very suggestive and point, in truth, to the existence of a veritable toxemia.

BARDEEN had a chance to examine systematically the organs of five children that died at intervals of from four to nine and one-half hours after extensive cutaneous burns. Without going into details, the microscopic findings may be summed up as consisting of parenchymatous degenerations in the liver, the kidneys and the lymphatic tissues. Of these changes those in the lymphatic tissues are the most interesting because they were so widely distributed, because of their severity in spite of the short time between the death and the burn, and because of their specific and focal nature, pointing to the presence of toxic substances in the plasma. Thus there were found numerous areas of cell fragmentation essentially like those produced by the toxic substances in diphtheria in children as well as in experimental inoculations in animals with various so-called toxalbumins. The character of the lesions described by BARDEEN furnish, therefore, important additional evidence of a toxemia after burns; destruction of red blood corpuscles and thrombosis did not seem to play so prominent a part in producing death as did the poisons in the blood plasma.

[2] Loc. cit.

THE PHYSICIAN'S PRIVATE DIAGNOSTIC LABORATORY.

The exactions of modern clinical diagnosis through the application of pathologic and bacteriologic methods have imposed new obligations upon medical practitioners. A few test-tubes and a spirit lamp no longer constitute a satisfactory laboratory outfit for a physician's office. To be abreast of the times, and to give his patients the benefit of the progress in medical science, a physician who conscientiously feels his obligations, must extend his laboratory practice far beyond the old confines of a search for albumin and sugar in the urine. The old microscope which has so long stood under the protection of a bell-glass, or has accumulated the dust of years in the closet, must be resurrected not alone to search for tube-casts and spermatozoa, but to take a place beside the thermometer and the stethoscope in daily practice.

The microscope, the test-tubes and the spirit lamp by no means constitute the requisite outfit. A number of additional pieces of laboratory equipment are required, until the office laboratory of the progressive physician becomes a miniature chemic, bacteriologic and pathologic laboratory. A small microtome and the centrifuge with its hematocrite are desirable; a simple sterilizer, incubator and paraffin bath are absolutely necessary; along with such glassware as test-tubes, flasks, slides and cover-glasses and a number of reagents. It fortunately happens that, aside from the microscope and microtome, the material necessary to equip a small working laboratory for purposes of clinical diagnosis is comparatively inexpensive, providing material of a simple character be chosen. A judicious outlay of $25 would supply the material necessary for a useful nucleus.

No doubt there are hundreds of physicians over the land who appreciate more or less keenly the desirability of employing laboratory methods in medical and surgical diagnosis, and to these individuals the item of expense in laboratory equipment would offer no obstacle. More serious objections are raised, and notably the one which confesses total ignorance of the methods of modern laboratory work. Here is indeed a serious stumbling block—one, unfortunately, which lies in the way not only of the older practitioner, but also before the majority of recent graduates in medicine, who imagined while they were in college that they were receiving "practical laboratory instruction," but who find themselves utterly helpless when the first tumor or the first case of diphtheria presents itself for diagnosis. The fault lies in an ignorance of laboratory technique which makes the would-be laboratory worker quite as helpless as one who aspired to do modern surgery while ignorant of the technique of hemostasis or of aseptic procedure.

How can this essential knowledge of laboratory manipulation be obtained? Obviously, by practice alone. This means that a reform should be inaugurated in a large portion of the laboratory instruction, as given today by medical schools, so that each student will be provided with a complete, simple laboratory outfit, and enabled to pursue all the steps of technical detail involved in an elementary study of such subjects as histology, bacteriology and pathology. Moreover, for graduates in medicine, identical courses should be offered involving the various methods of a laboratory diagnosis, until the steps in manipulation and the tools required become thoroughly familiar. Post-graduate laboratory courses should be made thoroughly practical in the full sense of the word, and thus attractive; and that army of graduates in medicine who are unfamiliar with laboratory methods should avail themselves of such courses instead of haunting the surgical and gynecologic clinics as is now the fashion. If more rural practitioners aspired to give their patients the benefit of a thorough diagnosis, and trained themselves for this purpose, the public and the profession would alike be benefited.

It is objected that laboratory work in medicine has become a specialty, and that it should be entrusted to the specialists in medical colleges, hospitals and boards of health. So far as advanced work is concerned this is true, and it is very desirable that laboratory specialism be recognized and duly encouraged. But there is no excuse for a physician who does not prepare himself to do the work demanded in routine daily practice. It would be quite as reasonable to argue that since there are cosmopolitan specialists in surgery no practitioner should open a boil; or because there are specialists in physical diagnosis no physician need possess, or perfect himself in the use of, the stethoscope and thermometer.

THE CONSERVATION OF THE OVARIES.

The reflex influence of the ovaries and testicles upon the animal organism has been so long a matter of common observation in the lower animals, that it would seem needless to offer any argument in favor of any question based upon it. The effects in the human species of castration in the male are also matters of common knowledge, but those of the corresponding operation on the human female seem to be still largely a matter in dispute. At least, such would be the inference from reading a discussion at the recent meeting of the American Association of Obstetricians and Gynecologists, reported in the October number of the *American Journal of Obstetrics*, where a paper on the conservation of the ovary, by Dr. B. SHERWOOD DUNN, was read and called forth various expressions of widely differing opinion. Dr. DUNN opened his communication with a reference to the opinion of BROWN-SÉQUARD that every gland, ductless or otherwise, gives to the blood some useful product, the loss of which by its extirpation is more or less severely felt in the economy, and after alluding to the researches of MOND, CHROBAK, MAINZER and others, gave the results of his own observations upon one hundred cases of complete oöphorectomy observed by him in the Broca and St. Louis Hospitals in Paris. In 78 per cent. there was subsequent loss of memory, in 60 per cent. vertigoes and heat flashes, in 50 per cent. change of character. Forty-two cases suffered from mental depression and ten were close upon melancholia. In 75 per cent. there was diminution of sexual desire, and varying percentages had other inconvenient symptoms after the operation. The troubles were generally the more marked in women under 30 or 35 years of age, and the deduction was that the theory of BROWN-SÉQUARD had a substantial basis of truth, and that removal of the ovaries in women before the menopause was undesirable.

In the discussion that followed, Dr. DUNN's views were supported by Drs. M. D. MANN, L. S. MCMURTRY and A. GOLDSPOHN, but the opinions of the majority of the speakers were more or less at variance with his ideas. It was held that castration did not make a woman feel unsexed, that conservatism often or even generally necessitated later operations, that the reported effects on the mental and emotional nature were not common and that the nervous and other symptoms described by the author of the paper were not observed in the general experience of gynecologic surgeons. Indeed, good results were claimed by some to be the more frequent the more thorough the extirpation, and the weight of opinion appeared to be against the conservatism recommended. The danger of the need of a subsequent operation was especially emphasized, and appeared to be, in the opinion of the majority of the speakers, a sufficient contraindication to such measures as the retention of a portion of the ovary that seemed unaffected by the disease requiring the removal of the remainder.

The psychic and physical consequences of castration in the male are so well known and evident that one would naturally expect to find something equivalent in the female from a like operation. It must be remembered, however, that these effects are less pronounced the later in life the operation is performed, and it is quite conceivable that many women who have suffered oophorectomy after the full establishment of the sexual functions may feel no special loss of womanhood and exhibit no marked physical indications of the change. Conventional notions have also less play in regard to this deprivation in the female than in the male, and this, as Dr. CUSHING suggested in the discussion, as reported, has an important bearing. In the woman, moreover, it is only an anticipation of a physiologic change which occurs before a very advanced age, and which has no exact analogue in the male, at least to any marked extent. These facts may therefore be taken as legitimately modifying the estimate we should put upon castration in the female as compared with the same operation in the other sex. Having said this much, however, we have made all the legitimate allowance that is required for the operation when not imperatively demanded by disease, and the statistics offered by Dr. DUNN are abundantly supported by other evidence of the serious functional and organic alterations that are liable to follow the too early induction of the menopause by operative interference. When it is spoken of, as it sometimes is, as justifiable in young girls, or its consequences in such are made light of, one is excusable in reserving a doubt and questioning whether the operative furor may not have had too full play and there may not have been less than the full judicial consideration of the circumstances that ought to have been given. Women suffer many inconveniences and pains connected with their sexual organization that they do not report even to physicians, and it is perfectly within the bounds of possibility that many symptoms following oöphorectomy are overlooked by operators. It is not easy to suppose that the operation which, however slight in its consequences in later life, cuts off the whole sexual life of a female, can be entirely without unpleasant results.

The fashion, for such it has been at one time, of removing ovaries for hysteria and other conditions without actual organic disease, has no good excuse, unless it may be the Malthusian one or that of preventing a perpetuation of a degenerate stock—both of them rather questionable reasons for any such procedures. Any undervaluation also of the possible moral, psychic or physical symptoms following castration in women is a result to be deprecated. If we are to accept, which it is to be hoped is not the case, the general tone of the discussion referred to as indicating that such is a prevalent tendency amongst gynecologists, the fact is one that is to be regretted.

RACE PROGRESS AND RACE DEGENERACY.

A paragraph has been going the rounds of the lay press stating that a distinguished paleontologist and professor in Yale University has pronounced that the Japanese at the present day possess the largest brains, and that therefore they are the coming race that are to rule the world in the near future. Whether he is correctly quoted or not can only be told by seeing his original publication, but the proverbial accuracy of the daily papers in publishing sensational items leaves an uncertainty in regard to this point. On top of this however, we find in a recent work by a presumedly prominent anthropologist, Prof. CHAS. PEARSON, that in his opinion the dark-skinned races are destined to outlast the lighter or Aryan group, and still another anthropologic specialist pronounces the opinion long since favored by certain of his European confrères, that in this country we are reverting to the type of the red man, thus affording us Americans at least a chance to get into the ranks of the majority when Truthful James' question as to whether the Caucasian is "played out" is finally answered in the affirmative.

Possibly, however, the future of the human race is not so altogether dark; there may be something better ahead than these scientists can forsee, that is, looking at it from our point of view. Just now it seems to be the fashion to take a pessimistic view of things; the times are out of joint to a large class of modern thinkers on social and other topics, and this may be only one of the signs of the times in this particular line. Degeneration of individuals and races is much more the theme of popularizing writers at least, and these prophecies may be rather incidents of the prevalent tendency than the results of the fullest scientific consideration of all the facts and possibilities.

It is a well-known and established principle that race progress and race retrogression depend rather on adaptation to environment than directly on cerebral development, however marked that may be. Europeans degenerate in the tropics and the Aryan Hindoo with all his metaphysical subtility, is, in all essentials, an inferior to his more practical Anglo-Saxon rulers. In the human species, moreover, the law of natural selection is only in part efficient; to a certain extent it is annulled, as Lawson Tait and others have long since pointed out, and there are a host of moral, social and political conditions that make or mar its progress. The environment therefore is a complex of conditions, only a small part of which are so thoroughly understood as to afford a basis for foretelling the outcome of any race or people beyond their immediate future. A scientific authority will hardly add materially to his reputation by venturing such prophetic utterances, except it be avowedly as a mere tentative opinion.

A recent French writer, Professor Schrader, has, in the *Revue Mensuelle* of the Paris School of Anthropology, offered some views in regard to this question of race advance or retrogression that are at least hopeful as to the future possibilities of what we have been accustomed to call the inferior races. He holds that, given a better environment, the most inferior race may become superior to all others, and that a race long resident in a certain *milieu* becomes best suited to it and, granted equal facilities, has the advantage over all others there resident; as an example he refers to the native population of Mexico, which though conquered and oppressed for centuries is now rising and furnishing the ruling class again in their country. There appears to be a degree of truth in this last statement, but the view he with others seems to hold, that the climate and soil affect the race type to produce that most suitable to them, which is that of the aboriginal inhabitants, is less encouraging. "Is it an illusion," he says, "that reveals to us in the physiognomy of the Yankee the hard bony face of the redskin?" This generalization of the idea that physical environment molds the human type is a favorite one with some European anthropologists, and its particular application is almost invariably made to this country and its European descended population. The physical peculiarities of the American aborigines are, after all, not so altogether objectionable; we can endure at least the contemplation of this prophesied fate of our race in this country, when we think of that of the portion of it that has displaced the Bushman and the Hottentot.

Speaking seriously, however, it may be repeated that speculations of this character are too indefinite and uncertain to be depended upon; they are much like Mark Twain's figurings on the length of the Mississippi—attempts to furnish the largest returns of theory from a minimal investment of facts. When in the distant future they, or anything like them, come to realization it will be as probably the result of factors not yet imagined as along the lines fancied by these prophets of science of the present. It is perfectly possible even that events may occur, as they have in the past, to check civilization and put the world some steps backward in its march, but it does not seem very probable that any very serious retrogression is at present imminent or that the inferior races are just now very rapidly coming to the top. It is safer and really more scientific to watch developments and to let such uncertain generalizations from the limited facts alone.

CORRESPONDENCE.

Treatment of Typhoid Fever.

Cleveland, Ohio, Oct. 12, 1897.

To the Editor:—Will you permit me to second the wise suggestion which appears in the Journal, of October 2, under the caption "A Way to Settle the Respective Merits of the 'Brand' and 'Woodbridge' Treatment of Typhoid Fever." Permit me, also, to assure your correspondent that I cheerfully accept all of his conditions and I will meet such a commission as he advises, whenever it may command my services and wherever it may choose to hold its sessions, whether in some typhoid stricken city in the United States, in England, on the Plains of Thessaly, or wherever the disease may occur; only show me the patients and I will supervise the treatment of as many cases of typhoid as may be necessary to enable the commission to make a *final* and *decisive* report. No one shall be taxed either for my services or for my expenses.

With the possibility of verifying the clinical diagnosis of typhoid fever by the diazo-reaction of Ehrlich and by the serum test of Widal, it ought to be possible to "settle" this much discussed question at once and forever. After having expressed myself in full accord with "M." on all of the essential points of his communication will he permit me to enter a mild protest against the, no doubt, unintentional injustice of including me in the deprecation of "the redolent with personalities" phase of a recent controversy. No one can abominate more than I do the "bitter personalities," yet it has been my lot to have been the recipient of more captious, unreasoning and even insulting criticisms, than perhaps, any other living man, and I would have been more than human or less than man if I had not resented some of them, but I appeal to the medical profession to witness that even in the heat of debate, and under the provocation of the grossest misrepresentations my speeches and my written communications have always been as free as possible from "offensive personalities," even in the controversy to which "M." alludes. I did not correct the erroneous statements or false inferences which referred to myself alone, although some then were calculated, if given credence, to do me grievous harm and as soon as the "mud pelting" was directed toward me alone, I at once *dropped* the correspondence.

Again placing myself at the command of the commission suggested by "M." I remain

Your most obedient servant,

JOHN ELIOT WOODBRIDGE, M.D.

Woodbridge Versus Typhoid Fever.

SAN DIEGO, CAL., Oct. 9, 1897.

To the Editor:—I heartily concur with your correspondent 'M." that the time is opportune to determine the status of Woodbridge's method as an abortifacient of typhoid fever. Certain it is that no just conclusion can be attained through acrimonious discussions in the medical journals, and meanwhile, possibly, humanity suffers. I would therefore suggest an appeal to the Académie de Médecine of Paris, members of which would doubtless be willing to pass upon a subject of such importance. There hospital and other facilities are unsurpassed, and it is well known that in times past its members have solved many problems of interest to the medical and scientific world.

For example, says Pereira, homeopathy has been fairly put to the test of experiment by some of the members of the Académie, and the result was a failure. Andral tried it on 140 patients, in the presence of the homeopathists themselves, adopting every requisite care and precaution, yet in not one instance was he successful!

At a later period, I believe members of the same distinguished body, with the active concurrence of Gull and Spurzheim, investigated the claims of phrenology and declared many of them untenable.

Within the recollection of the writer, specimens (roots) of the sarracenia purpurea, at that time a much vaunted remedy for smallpox among whites and Indians of Canada, were forwarded to the Académie and after a thorough trial were found to be inert.

I propose then that Parke, Davis & Co., already widely and favorably known for their interest in the advancement of materia medica, etc., transmit the necessary literature and a sufficiency of their Woodbridge tablets to the Académie de Médecine, requesting a thorough investigation of their possibilities in typhoid fever. I am sufficiently interested to assist in paying the expense if necessary. C. M. FENN, M.D.

An Interesting Case.

FORT SMITH, ARK., Sept. 28, 1897.

To the Editor:—In 1895, while in charge of the U. S. Jail at this place, I treated a very interesting case. A strong, robust young man, during the progress of a fight, received a severe contused wound about two inches in length and laying bare the frontal bone just over the right eye, which in spite of the ordinary antiseptic treatment proceeded to suppurate very freely, and, notwithstanding bichlorid douches and iodoform dressings were faithfully employed, the process was not stayed, but rather increased. On the third day after the injury, in an insignificant little scratch on the cheek two or three inches below and to the outer side of the eye, erysipelas developed and rapidly spread until the whole face was involved, and at the second removal of the dressing after the wound became involved in the erysipelatous process, I found it firmly sealed by a dry scab and presenting no evidence of pus. Being anxious to see the outcome this was not disturbed and the face was lightly covered with absorbent cotton saturated with bichlorid of mercury 1 to 2,000, which application I had been using in the treatment of the erysipelas. Now from this fourth day there was not an untoward symptom or a drop of pus in or about this wound, and when the scab dropped off I found a nicely and perfectly cicatrized scar. The stitches were allowed to remain in the wound nineteen days, and when removed, notwithstanding there had been stitch abscesses developed during the first two or three days, were found firmly inpacted in the tissues, requiring some little effort in their removal, and I firmly believe had they not been reinfected from without they would have remained indefinitely in the tissues without producing any irritation or inflammation.

This case was reported at the time at our local medical society with the prediction that a toxin would be found which when introduced into the body would be fatal to the germs of suppuration and infection, and it seems that my prediction is thus early about to be verified. W. R. BROOKSHER, M.D.

Report of Three Cases of Asphyxia from Submersion.

GREENVILLE, TEXAS, Oct. 16, 1897.

To the Editor:—I deem it necessary to preface this letter with some preliminary remarks bearing upon this unfortunate affair. These cases consisted of one prominent wealthy man, and two young women. There are various rumors and finespun theories by the laity, relative to the causes and reasons why this drowning occurred.

The examination of the bodies was not made at the place of drowning, which was due to oversight on the part of the coroner. I was summoned to make examination of the bodies after they were brought to town, which was about ten hours after the accident.

I obtained the following facts from reliable members of the searching party, as follows: The drowning occurred Wednesday about 10 P.M. on June 18, 1897, about six miles northwest of Greenville, in a "pasture pool." There were two men and two women, and one of the men was fortunate to escape alive and report the affair.

One of the searching parties arrived from the neighborhood about two hours afterward and they observed one of the bodies floating. The searching party from Greenville arrived upon the scene about 1 A.M. and immediately removed the floating body, it being in shallow water. Rigor mortis had not set in in this case. The other two bodies were not removed until 4 A.M., and they were found in ten feet of water and rigor mortis had taken place. I made a careful examination of the bodies and found that all three of these cases presented practically all the external signs of asphyxia due to submersion and gave my opinion, based upon the statement of the only eye witness and searching parties, that they met their death by accidental drowning.

The special point of scientific interest was why one of these bodies was found floating two hours after accident, and two were at the bottom of pool. The floating one was found in about five feet of water at an inclined angle, with the face at the surface of the water. The other two (the man and the most corpulent woman) were close to each other in about ten feet of water at the bottom of the pool.

These people drowned at the same time in close proximity to each other in the same pool. The water was clear and not stagnant, and the temperature of air and water was the same for each case. The women had on loose wrappers and the man an undershirt and an old pair of trousers when found.

The time for submerged bodies to float depends upon such varied conditions that no absolute period can be fixed for all cases.

It is my purpose to call attention to the unusual occurrence of one of these bodies floating at least two hours after the accident.

The specific gravity of a human body is slightly heavier than water, and it will not float immediately. I present the following reasons as the cause of this body floating:

1. She was found in shallow water, and the weight of the superimposed water may have kept the other two bodies from rising.
2. The body being in shallow water, putrefaction, with formation of gases, would be more apt to take place than in those completely submerged.
3. I learned from a colleague of mine that this person was being treated for fermentative or flatulent dyspepsia, and this, in connection with beverages and lunch prior to bathing, may have caused excessive formation of gases in the stomach, also in the small intestine.
4. If no water was taken into the lungs and she died with the lungs full of air, then the specific gravity of the body would be made lighter than otherwise.

The day after the inquest, it was alleged by some of the laity that the reason the woman floated was due to pregnancy. I am not in a position to state whether she was in that condition, as a postmortem was not made. Now to the point: Will a pregnant woman be more liable to float than if she was not pregnant, conditions being the same?

J. R. Nichols, M.D.

Goat's Blood and Milk.

Reply to Dr. Parker's Inquiry as to the Use of Goat's Blood and Milk in the Treatment of Disease. Translated from the French (Transactions Congress for the Study of Tuberculosis, Session of 1891.)

New York City, October, 1897.

To the Edtor:—"In a work published last year we have shown that it is advantageous to substitute the goat to the cow for vaccinating purposes. The goat is refractory to tuberculosis, not when she is inoculated only, but in the ordinary tenor of its existence. When rabbits were inoculated with tuberculosis, if goat's blood was transfused into them the same day, these rabbits resisted inoculation; if the transfusion was strong after inoculation the tuberculous processes retrograded and were cured. The transfused goat's blood determines then, in the rabbits, a bactericide condition. Could not it act similarly on man? As the transfusion of animal blood to man was not without danger, we recurred to subcutaneous injections or even intramuscular injections of goat's blood, complete and fresh. The injections were of 15 to 20 gr. and repeated three or four times in the same patient with intervals of ten to fifteen days. Of 110 patients, 10 had abscesses, 50 to 60 urticaria. The patients who suffered with laryngeal phthisis reaped no benefit from these injections; in the cases of pulmonary caverns there were some ameliorations. The amelioration was evident in the cases of tubercular bronchitis, tuberculosis of the first degree, ganglionary tuberculosis, osseous tuberculosis and the lupus."—Bertin and Picq.

Transfusion of goat's blood in pulmonary tuberculosis.—"The goat is refractory to tuberculosis as I have seen by the autopsies of forty-eight individuals and by the injection (intravenal) of bacilli into four others. While the rabbits inoculated with tuberculosis die within two months if they are left without treatment, those injected with goat's blood die less quickly, and those into which this blood is transfused present caseous foci but without generalization. I have satisfied myself by other experiments that the transfusion of blood from one animal to the other is not dangerous. I have, therefore, transfused goat's blood into man. The apparatus which I used consists of two trocars, joined by a rubber tube; the one, rather voluminous, is introduced into the carotid of the goat, the other, capillary, into the cephalic vein of the patient; 100 to 120 grams of blood may be transfused in one minute. The first sittings must not last longer than fifteen to thirty seconds, the subsequent ones more than one minute. I have thus treated two chloro-anemics, who were cured; seven tuberculous of the second, one of the first degree, who may be considered as cured, inasmuch as their general condition is good and the physical symptoms as well as the bacilli have disappeared; three more tuberculous who were ameliorated; finally two, who at first ameliorated, have since died rather rapidly. A last patient who had reached the last degree of cachexia, died of syncope in the course of the transfusion."—M. Bernheim.

Immunity against cholera by goat's milk.—M. Gamaleia presents a work on the immunity against cholera imparted by the milk of goats, composed on his advice and under his direction by Dr. Ketscher of St. Petersburg. In the present time the pandemic extension of cholera has specially directed the efforts of bacteriologists to discovering effective means of combating this scourge. Thus have been imagined of late, divers methods of vaccination, which have more or less in common with the well known studies of Ferrau. But despite the innocuousness of most of these methods they have not been practically applied even during the most devastating epidemics, as that of Hamburg; for preventive vaccination is not a national measure, adapted to a struggle against an acute disease like cholera, which affect only a minority of the population. The less so that bacteriology, not content with its ability to obviate infectious diseases, has made important progress, allowing it to defeat even declared affections. Everyone knows something about serotherapy, or the treatment of infections by the serum of vaccinated animals. But the use of serum presents a certain number of drawbacks which hinders its introduction into practice, especially for cholera. Another immunizing fluid furnished by the vaccinated animal's milk is without any of them. It is for this reason that M. Ketscher has studied the immunizing properties of milk in cholera. For these experiments he has employed the most virulent cultures of cholera, sent him from Massua. The goats were vaccinated by subcutaneous, *intraperitoneal* and *intravenous injection* of these cultures. The immunizing power of their milk was observed in the following series of experiments by means of its introduction into the peritoneum of the guinea pigs. The chief results of his experiences are as follows: The milk of the vaccinated goat injected at the doses of 5 c.c. has the property of vaccinating the guinea pigs against a mortal dose of cholera (½ c.c. injected into the peritoneum). The guinea pigs which had received the milk remained well, while the witnesses succumbed in the first six to ten hours after the inoculation of the virus. In order to make out whether the milk acts only directly upon the cholera vibriones or also upon the whole vaccinated organism, M. Ketscher varied his experiments by injecting the cholera cultures in another place than in the peritoneum, especially in the muscles of the posterior extremities; this mode of infection gave exactly the same results as the preceding. The guinea pigs prepared by the milk lived, the witnesses succumbed six to eight hours after the infection. These experiments show that the milk of vaccinated goat injected into the peritoneum of the guinea pigs renders them *refractory to a mor-*

tal dose of cholera. It is not without importance to add that the milk of the non-vaccinated goats, which M. Ketscher has repeatedly tried, possesses no immunizing power. By another series of experiments he has studied the curative power of milk. For this purpose he injected a mortal dose of cholera into the muscles or peritoneum of the guinea pigs and then treated them by the intraperitoneal introduction of goat's milk. In these cases the guinea pigs treated showed some symptoms of infection, for instance, a slight edema on the inoculated thigh. But these symptoms vanished altogether in a short while and the guinea pigs survived. The witnesses invariably perished. It follows that the milk of a vaccinated goat injected into the peritoneum of guinea pigs not only vaccinates them against future infection, but cures even the declared disease."

Albert S. Ashmead, M.D.

Surgical Treatment of Impotence.

Chicago, Oct. 9, 1897.

To the Editor:—In your Journal of Oct. 9, 1897, you published an article by J. A. Murray, M.D., entitled "Ligation of the Dorsal Vein of the Penis for Functional Impotence With Report of five Cases."

In this article the Doctor states that he has seen no literature on the subject, but further says that he does not claim priority of discovery for the operation.

The first case reported advocating this operation was by Dr. Waugh formerly of Philadelphia, and now of this city, in the *Southern Clinic*, 1893, Vol. xvi.

In 1893 I did the operation for the first time after having seen Dr. Waugh's article, and have since then performed it twice. In all three cases I had good results.

Evert E. Tracy, M.D.

NECROLOGY.

Surgeon General Newton L. Bates of the navy, the President's family physician, died at the Shoreham hotel, Washington, D. C., October 18, at half-past nine, of a renal trouble. He was appointed Surgeon General about two weeks ago, to succeed Surgeon General Tryon, and was obliged on account of the illness which finally resulted in his death to take the oath of office in bed. He entered the navy from New York State in June, 1861, and prior to his appointment as Surgeon General was a medical director, with the relative rank of Captain, and was on duty at the Naval Museum of Hygiene in Washington.

Rodolphe Heidenhain, M.D., incumbent of the Chair of Physiology at the University of Breslau, according to a cablegram dated October 14, is dead. He was born at Marienwerder, Jan. 19, 1834, studied medicine and natural science at the Universities of Koenigsberg, Halle and Berlin, and after receiving his diploma in 1854, entered the laboratory of Professor Du Bois-Reymond, under whose direction he conducted his researches in experimental physiology. He was appointed to the chair of Physiology at Breslau in 1859. Among his best known publications are: "Studies in Physiology," "The Physiology of Secretion," "Animal Magnetism, so-called," and "Vivisection Applied to Medical Art."

Walter E. Anthony, M.D., New York University, 1867, at his home in Providence, R. I., aged 50 years.——Oliver M. Doyle, M.D., University of Pennsylvania, 1856, died at Calhoun, S. C., October 6.——George R. Hunt, M.D., at Warrensburg, Mo., October 4, aged 73 years.——Timothy D. Connor, M.D., Springwater, N. Y., October 8, aged 65 years.——Richard D. Cowan, M.D., Rolla, N. D., October 7, aged 42 years.——Theodore Munro, M.D., Union, S. C., October 10.——Vespasian Smith, M.D., Duluth, Minn., October 11, aged 79 years.——Andrew J. Spalding, M.D., Leonardtown, Md., October 5.

PUBLIC HEALTH.

Yellow Fever.—The dispatches of the 12th closed our record in last week's Journal. This week we have the following data: October 13.—New Orleans, 9 deaths, 27 new cases; Mobile, 7 new cases in the city proper, and 6 brought in from Magazine Point; Wagar, Ala., 1 death, 1 new case; Nittayuma, 1 new case; Edwards, 3 new cases and and 1 death, October 14.—New Orleans, 4 deaths, 41 new cases. The "suspicious" cases at San Antonio, Tex., were on this date claimed not to be yellow fever, and there were no new cases at Galveston. Mobile, 5 new cases, 1 death; Flomatom Junction, Ala., 8 cases; Franklin, La., 1 death; Bayminette, Ala., 1 death; McHenry, Miss., 6 cases; Edwards, 6 cases; Clinton, 1 death; Biloxi, 13 cases and 1 death. October 15.—New Orleans, 44 new cases, 3 deaths; Mobile, 5 new cases. October 16.—New Orleans, 22 new cases, 1 death; McHenry, Miss., 1 new case; Edwards, 5 new cases, 1 death; Nittayuma, 1 new case; Cayuga, 4 new cases; Mobile, 7 new cases; Wagar, Ala., 1 death. October 17, the deaths at New Orleans numbered 5, with 24 new cases; Bay St. Louis, 7 new cases and 1 "suspicious" case. October 18, the death list at New Orleans reached the hundred mark, as 7 deaths were reported on this date. The new cases numbered 37, bringing the total cases at New Orleans, to date up to 865, of which 322 are still under treatment. At McHenry, 2 new cases were reported; 12 new cases at Scranton; 2 new cases at Pascagoula; 16 new cases at Biloxi; Mobile, 6 new cases, and 1 death, making the total cases there to date, 170, and the total deaths, 22. Cayuga reports 2 new cases and 2 "suspicious" cases, with 1 death. Edwards reports 2 new cases, and 3 deaths. Montgomery, Ala., reports 2 cases, with a few "suspicious" cases. Franklin, La., 2 cases, and 1 death near Patterson, La. Dispatches of October 19 give no encouragement in the situation at New Orleans, there being 56 new cases and 4 deaths reported.

The Cost of the Yellow Fever.—Although there has been comparatively little loss of life in yellow fever districts of the South, there has been a tremendous loss of money to the community because of the contagion. The New York *Herald* says it is estimated that the loss to the business men in New Orleans alone will amount to $25,000,000, while the losses in other directions and the cost of maintaining the quarantine will run the total up to $38,000,000. Most of this loss is the result of the wild and unreasonable excitement of the neighboring towns and villages that have shut off all supplies shipped from New Orleans and have absolutely paralyzed business in that city.

Typhoid Fever and Damage Suits Against Municipalities.—The *Lancet* remarks that the city fathers of Yarmouth, England, have, by a narrow margin, escaped being mulcted in damages for having been the unwitting means of causing fatality by typhoid fever, in the course of their construction of a very necessary sanitary improvement, which was intended to have a precisely contrary result. The Court of Queen's Bench was occupied for three days in hearing the evidence on this point. It appears that a new sewer was being laid down in Queen street, and that shortly afterward a resident in this street complained that the water in a well situated in the basement of his house was foul and that he and others had been made ill by its consumption. He attributed the contamination of the water to percolation of sewage, which was alleged to have found its way into the trench dug for the reception of the new sewer. A month later the complainant, Mr. Durrant, sickened with typhoid fever, from which he died. An action was brought by his executors claiming damages from the corporation for having, through their negligence, caused the pollution of the well and the death of Mr. Durrant. Without entering into the question as to whether the consumption of this water was the cause of his fatal illness or not, and even admitting this possibility, the defence went to show that the well could not have been contaminated by the temporary disturbance of the soil thirty-six feet distant, but that it was, and probably had been long fouled by leakage from a privy situated at a higher level, only sixteen feet away. For after the well had been daily pumped out for a month the water remained still highly impure. As Mr. Justice Hawkins remarked, the poisonous contamination of the well was a singular coincidence at the time of the progress of the works, and the jury gave a verdict for the defendant.

The Home in Its Relations to Tubercular Consumption.—Dr. R. Thorne Thorne, in the "St. Bartholomew's Hospital Reports," thus states the case as to phthisis in the domicile: Conditions of dwelling house tending to the promotion of tubercular consumption.—1. A soil either naturally damp and cold or subject to the influence of the rise and fall of a subsoil water lying within a few feet of the surface. 2. A dwelling house of which either the foundations, the area they inclose, or the walls are, by reason of faulty construction or otherwise, liable to dampness. 3. Such immediate surroundings of the dwelling house as tend to prevent the free movement of air about it, and its ample exposure to the influence of sunlight. 4. Such structural defects as would prevent the maintenance within all parts of the dwelling house of ample movement of air by day and by night, and free exposure of its habitable rooms to daylight.

Conditions of dwelling house tending to the prevention of tubercular consumption.—1. A soil which is dry naturally, or freed by artificial means from the injurious influence of dampness and of the oscillations of underlying subsoil water. 2. A dwelling house so constructed as to be protected against dampness of site, foundations and walls. 3. Such open space on at least the two opposite sides of the dwelling house as shall secure ample movement of air about it, together with its free exposure to the influence of sunlight. 4. Such construction of the dwelling house as will secure for its habitable rooms, and throughout its interior, free movement of air by day and by night, and free access of daylight.

On the Convection of Plague by Merchandise.—The editor of the *Lancet* considers the above subject in a leader designed to set forth the kind of proof that is offered to prove the affirmative of the question as against merchandise, such as cotton, wool, etc., from the Orient. At the present time, when we read of the action of certain European powers in respect to cargoes of cotton from plague-invaded ports, it may not be out of place to inquire briefly on what evidence this fear of the importation of plague through the agency of such articles as cotton or wool is based. It is an easy matter to assume that when an infectious disease is prevalent within any given district, there may be fear of such disease being conveyed through the agency of merchandise from the invaded center; but when we ask upon what evidence this fear is based, we are not so easily supplied with an answer which is proof against destructive criticism. We read in the text-books, of plague having been conveyed from one place to another through the agency of bales of cotton or wool, but the evidence which is given as supporting this statement is, as a rule, somewhat scanty. Indeed, it seems that when some of these questions are approached in a spirit of unbiased inquiry there is but little evidence tending to support the text-book statements. For instance, among European nations the French are not behindhand in their dread of the importation of infection through the agency of certain merchandise from infected Indian ports, but it does not seem that the French in taking up this attitude, are mindful of a certain report which was made to the French government in 1846, by a Special Commission appointed by the French Academy of Medicine, upon this very subject, and which report was brought before the Lord President of the Privy Council by Sir John Simon in 1875. In bringing forward the evidence adduced in this report, Sir John Simon pointed out that western Europe had not suffered from plague for more than one hundred and fifty years, and that up till quite recently the disease had been frequent in the Levant, from which plague-invaded district wool had in all times been exported without apparently any case of plague having been caused thereby. We are far from asserting that it is impossible for plague, when its virus is in a certain phase of activity, to be conveyed through the agency of cotton or wool, but in endeavoring to arrive at any conclusion on this question the very important negative evidence furnished above should receive its due share of consideration; and it is to be regretted that articles on plague in the textbooks are, for the most part, silent as to the conclusions of the French Commission, although at least sufficient prominence is given to "reports" in the other direction. If action were taken upon the statements contained in some of the textbooks, it is conceivable that under certain circumstances much misery might be produced in some of the manufacturing districts of England, loss and misery which would be, perhaps, hardly justified upon the evidence obtainable on this point.

The Malarial Hand.—Dr. Edward Craster, a governmental officer, resident on the West coast of Africa, invites attention to a diagnostic coloration of the hand that is, in his opinion, malarial in origin. He says, in the London *Lancet*, for September 4: "It is well known that long residence in a malarial climate causes, in a large majority of cases, such changes in the coloring matter of the skin that, instead of 'sunburn' a peculiar 'putty-like' appearance is produced. With some this appearance disappears after a short residence at home, with others it is permanent. This 'West-coast complexion' is so commonly recognized as to need no comment here. The peculiar phenomenon to which I wish to draw the attention of the profession is one which I have called 'the malarial hand.' I have noticed during my sojourn in the Niger territories, among those Europeans who have resided on the Niger more than two years, a singular rose-pink coloration of the skin over the thenar and hypothenar eminences and also over the under surfaces of the last phalanges of both hands. This coloration comes on imperceptibly and increases gradually until the appearance is as if these surfaces had been dipped in red ink. I have not noticed it in persons of any particular complexion, but it seems to affect fair and dark alike, and it always appears simultaneously on both hands, never on one alone or on one before the other. It would be very interesting to hear if a similar manifestation exists in other malarial climates, and if so to what it has been ascribed. Personally I am not yet in a position to give an opinion on the subject, but would be much interested to hear that of confrères who have noticed the peculiarity."

SOCIETY NEWS.

The Newport Sanitary Protective Association met at Newport, R. I., October 8. The following were elected officers for the ensuing year: President, Elbridge T. Gerry; first vice president, James J. Van Alen; second vice-president, A. B. Almon; treasurer, Peter F. Curley, M.D.; recording secretary, Creighton Withers; corresponding secretary, H. R. Storer, M.D.; honorary counsel, Samuel R. Honey; consulting engineer, George E. Waring, Jr.; inspectors, William H. Chapman and George W. Farquhar.

The National Sanitary Association met at Nashville, Tenn., October 13. Papers by Dr. Charles S. Benedict, Dr. Thomas C. Craig and President Young were read and discussed. The Association elected the following officers: President, Dr. Charles E. Benedict; vice presidents, Dr. H. C. McLean and Dr. F. L. Jewett, both of Brooklyn; Dr. E. A. Wilson, Meriden, Conn.; secretary and treasurer, Dr. Thomas E. Veal of Atlanta, Ga. New York City was selected as the next place of meeting.

MISCELLANY.

Personal.—H. Augustus Wilson, M.D., has severed his connection with the Polyclinic Staff, Philadelphia.

New Journals.—*Edwards' Journal of Health*, Vol. i, No. 1, October, 1897, has been received. It is edited and published monthly by Joseph F. Edwards, A.M., M.D., Atlantic City, N. J. *The National Hospital and Sanitarium Record* is a new publication published in Detroit, Mich., Vol. i, No. 2, September, 1897, being noted among our exchanges.

Death from Ivy Poisoning.—A death is reported from Chester, near Middletown, N. Y., from rather an unusual cause, the effects of ivy poisoning. The patient was a female, 69 years of age, who came in contact with the plant early in July. Her whole system seemed to be profoundly affected by the poison and death resulted after two months of great suffering.—*Boston Medical and Surgical Journal.*

Not an Unreasonable Contract.—There is no manifest unreasonableness, the supreme court of Rhode Island holds, Tillinghast vs. Boothby, in such a contract as one by which a certain person was employed to work as a dentist, with a stipulation that he would not, after the termination of the contract, "either directly or indirectly, carry on, or be employed or concerned in, the practice of dentistry in the county of Providence, Rhode Island."

Intracorpuscular Parasites in Birds.—Danilewsky, who first observed intracorpuscular parasites in the blood of birds, believes that these organisms are identical with those of the malarial fevers. Certain subsequent observers have attempted to establish an analogy between the different varieties of the malarial parasites and forms which they find in birds. Others have considered the parasites in birds to be entirely independent of those of man. It seems probable that there are in birds at least two distinct species of intracorpuscular parasites. In almost every detail of structure they very closely resemble the malarial organisms of man, but they are, nevertheless, essentially distinct.

Observation of Conduct.—In Burt v. State, a murder case, where the defense was insanity, the court of criminal appeals of Texas says that it is not informed of any case holding that because a prisoner is in jail, unwarned, therefore his conduct can not be observed, so that an expert can give an opinion as to his sanity. It would be a remarkable case, indeed, the court goes on to say, in which the accused, if insane, would simulate sanity. Nor can it comprehend how the fact that he was in jail could affect his conduct in this particular in any manner. Consequently, it holds that the testimony of a medical expert who has carefully observed the conduct of a prisoner under such circumstances is admissible in evidence on the question of his sanity.

A Diagnostic Point Worth Knowing.—A young physician of East Liberty, who was called to see a consumptive patient in the absence of the family doctor, was asked by the patient's sister, in anxious tones: "Doctor, are consumptive persons full of bugs?" "Bugs?" repeated the physician, doubtfully. "Yes; our doctor says they are full of bugs." "Oh," he replied, "your doctor probably told you of the bacilli tuberculosis, but they can't be called bugs. They are very small creatures. I forget their exact size, but it would take probably 10,000 to make an inch, and they can not be seen except by the highest power of the most powerful telescope." The questioner listened doubtfully and then said: "Well, anyhow, my sister can feel them crawling inside her."—*Pittsburg Chronicle-Telegraph.*

Statements to Physicians.—The Court of Appeals of Kentucky takes the position, in the case of Omberg v. United States Mutual Association, that the declarations of a patient to his attending physician with regard to what his injury is or was caused by are competent evidence where the cause of his injury is in issue. A narrative of the events attending the mishap, it goes on to state, would not be competent, but the patient may tell what the injury is, if he knows. He is suffering, and is seeking relief. To get it he must tell the truth. Any other course would mislead his physician, and might result disastrously. But the court says that it is not disposed, for obvious reasons, to extend this doctrine so as to embrace declarations made to others than the patient's physicians.

Rectal Feeding in Typhoid Fever.—For some time past Dr. Queirolo, Professor of Clinical Medicine in the University of Pisa, has been in the habit of feeding his cases of typhoid fever entirely by the rectum in order to afford the diseased bowel complete rest. The nutrient enemata are given four times daily, and consists of triturated meat and pancreas with a few drops of laudanum, each injection being preceded by irrigation of the bowel with boracic acid—the plan, in fact, advocated by Leube. The patients are allowed to drink hydrochloric acid lemonade. In this way the digestive tract is preserved from putrescible substances, and this Dr. Queirolo considers obviates one of the most fruitful sources of auto-toxic action. All the cases treated on this system, many of them a very severe type, are stated to have recovered.—London *Lancet.*

A Danger from the Underground Wire.—Electrolysis is damaging the water-pipes at Springfield, Mass., as well as elswhere. A water engineer of that city in describing a volt meter test of an affected pipe, says: "To my mind the solution of these queer antics is that the return wire at the point where the current showed was not as good a conductor as the iron pipe which runs along Belmont Avenue. When the current neared the pipe which we are discussing, the ground was wet and the current left the main pipe and entered this one. The current does no harm so long as it runs along the pipe, but when it leaves the pipe for some other connection it raises mischief. Iron pipe is affected as badly as lead pipe. Sometimes a pipe will be ruined in three or four weeks. In Brooklyn, cases have been reported where three or four days have spoiled the pipe. But this is not a circumstance to what happened on State Street. There a pipe had been cut off and plugged in close proximity to another line. The amount of electricity in the plugged line pipe was something remarkable. I took and wired a pen to it and held it with a rubber mitten, and it would emit sparks two or three feet long. I then held the pen a short distance from the second line of pipe and found that I could mark the pipe, in fact, could write my name as easily as a diamond writes upon the glass."

Power of Railway Officials to Employ Physicians.—A judgment for the value of medical services rendered railway employes was affirmed by the appellate court of Indiana in the case of Bedford Belt Railway Company v. McDonald. The court said that a railway corporation is under no different obligation to procure medical and surgical aid for its employes than is any other corporation or person under like circumstances. At the same time it is well settled that the general officers of a railway company have power to employ medical attendance for workmen injured in the performance of duty in the company's service. Subordinate officers or agents can only do so in cases of urgent exigency. The court further said that it failed to see any difference, in effect, between a corporation, through its general officers, employing a surgeon at the time an employe is injured and employing him in advance to render services to an employe only in the event that the employe is injured. But it would not decide here whether a corporation has power to employ a surgeon at a stated salary, which he is to receive in any event, though it stated that it did not consider that such a contract would be against public policy or an invasion of the rights of injured employes. There can be no presumption that the amount paid the surgeon by the company is deducted from the wages of the injured employes, nor that such a contract as the foregoing cuts off the right of an injured employe to call in any surgeon he may choose.

Termination of Liability for Care at Hospital.—St. Barnabas Hospital v. Minneapolis Electric Company, is the title of an action brought to recover for the care and treatment of one of the employes of the defendant company, whom it had taken, after he had been seriously injured, to the hospital named, where he was received as a patient for an indefinite period, no length of time being mentioned, at the company's request and upon its promise to pay for his care and treatment. Subsequently, and while the patient was yet incapable of being removed or discharged from the hospital without great danger to his life or health, the company gave notice that thereafter it would not be responsible for his care or treatment. Could the company thus terminate its liability, especially at such a time? The supreme court of Minnesota holds not. It holds that under the circumstances it was an implied condition of the contract that the company could only terminate its liability by removing the patient or when he could be dismissed by the hospital without serious danger to his life or health. In order to relieve itself from liability for care and treatment furnished after the notice on the ground that the patient had means of his own to pay for it, the court further holds that the burden was on the company to prove that he had means out of which the hospital could and should have collected its pay. But for the hospital to maintain its action, the court intimates that the burden belonged to it to prove that the patient could not have been dismissed without great danger to his health or life until the date of his dismissal, or that at least it could not recover pay after the notice against the company beyond the time to which it proved that such condition extended.

X-ray Photographs as Evidence.—In the course of the trial of the personal injury case of Bruce v. Beall, a medical expert, Dr. Galtman, was introduced as a witness, and he was permitted to submit to the jury an X-ray photograph taken by him, showing the overlapping bones of one of the plaintiff's legs, at the point where it was broken by the fall which was charged to the defendant's negligence. This was objected to by the defendant's counsel. The photograph was taken by the witness, who was a physician and surgeon, not only familiar with fractures, but with the new and interesting process by which this particular impression was secured. He testified that this photograph accurately represented the condition of the leg at the point of fracture in question, and, as a fact, that by the aid of X-rays he was enabled to see the broken and overlapping bones with his own eyes, exactly as if stripped of the skin and tissues they were uncovered to the sight. After calling attention to these facts the supreme court of Tennessee says that it might, if it so desired, rest its conclusions on the general character of the exceptions taken to this testimony, but that it prefers to place it on the ground that, verified by this picture, it was altogether competent for the purpose for which it was offered. New as this process is, continues the court, experiments made by scientific men, as shown by this record, have demonstrated its power to reveal to the natural eye the entire structure of the human body, and that its various parts can be photographed as its exterior surface has been and now is. No sound reason was assigned at the bar why a civil court should not avail itself of this invention, when it was apparent that it would serve to throw light on the matter in controversy. Maps and diagrams, drawn by hand, and photographs of exterior surfaces have been admissible in numerous cases. It is not to be understood, however, adds the court, that every photograph offered as taken by the cathode or X-ray process would be admissible. Its competency, to be first determined by the trial judge, depends upon the science, skill, experience and intelligence of the party making the picture and testifying with regard to it, and, lacking these important qualifications, it should not be admitted; and, again, even when it is not conclusive upon the triers of fact, it is to be weighed like other competent evidence.

Insanity Abroad on the Increase.—There has been a deal of comment of late on the increase of insanity in England. It seems from an official report that a similar, if not a worse, condition of affairs exists in Prussia, where the lunatic asylums find difficulty in providing accommodations for the crowds of applicants for admission. In 1871 the total number of lunatics in Prussia was 55,063, in 1880 it had risen to 66,345, while in 1896 it had gone up to 82,850. It is interesting to note also that, while the growth of insanity is general, it is more marked among men than among women. Of 100,000 Prussian males it seems 278 are found insane; but in a like number of women only 243. From figures given in the same return it appears that blindness is diminishing, while the number of deaf mutes is rather increasing.—*N. Y. Evening Post.*

Classification of Epilepsy.—Dr. Frederick Peterson, President of the Board of Managers of the Craig Colony of Epileptics, has the following to say in his third annual report regarding the classification of this disease: "So little is known of the etiology of epilepsy that it is not possible, in the light of present knowledge, to make a satisfactory classification of its forms. The terms grand mal, petit mal, psychic and Jacksonian are largely symptomatic designations, and bear little relation to causative factors. A classification based strictly on etiology is not possible, but none will deny that such a classification would be more scientific and valuable. The classification here offered is not held to be perfect or even satisfactory, but is used as a working basis for future improvement: 1, genitoneuropathic; 2, post-paralytic; 3, traumatic; 4, hystero-epilepsy; 5, hereditary; 6, imbecilic; 7, acquired; 8, senile."

Limit to Power of Health Officers.—The question was presented in the case of Eckhardt v. City of Buffalo, whether, under a general power to declare certain matters and things to be nuisances, and to abate the same in such manner as the official may deem expedient, the power may be implied to cause new erections to be made, new appliances, apparatus and contrivances to be used and new improvements to be adopted, all in accordance with supposed scientific principles of sanitation, and to charge the expense, however costly it may be, to the landowner, whether he will or no? This, the fourth appellate division of the supreme court of New York answers in the negative. Or, to be more specific, the court holds that a health commissioner, given by statute only power to abate nuisances, has not the right or power to force on a landowner the mechanical contrivance of water-closets, with all their requisites and accessories, instead of privies, which, sufficient as privies, if kept in the condition proper for such conveniences, are on his lands for the purposes of his building there. No such extensive powers exist at common law. The conservation of public interests and the people's health and safety, says the court, must be looked to, but at the same time private rights of property must be guarded and protected against unwarrantable invasion, and the undue exercise of authority must be restrained within reasonable and proper bounds. The fact that a privy may not conform in all its appointments and accessories to the most approved modes of scientific sanitary plumbing does not of itself condemn it as a nuisance. Besides, the right to abate is limited to the removal of that in which the nuisance consists. Nor does the court think that the existence of Asiatic cholera in the seaports of Europe, having connection with the city of Buffalo, N. Y., would put inhabitants of the latter place in great and imminent peril, such as to warrant the health commissioner compelling them to incur large expenses in the improvement of their property, far beyond what the ordinary exigencies or necessities would require.

Danger from Gauze Tampons in Postpartum Hemorrhage.—Schaeffer regards with disfavor the use of gauze as a material for uterine tampons in cases of flooding. If impregnated with iodoform or some other antiseptic, there is no danger of sepsis. If, however, it should happen, as is often the case, that the tampon fails to stimulate uterine contractions, and if when the bleeding is from a lacerated cervix the plug does not cause the torn artery to close by thrombosis, the gauze increases the danger, for it acts as a capillary drain and takes up much blood. All who have attended many labors know that the tolerance of hemorrhage is very irregular in different subjects, and an apparently trifling loss will kill certain women. Hence, the best rule in flooding is not to allow one drop more to be shed, if possible. Gauze, above all, if "absorbent," which simply means more absorbent than commoner material, at least takes up many drops of blood. Schaeffer now uses non-absorbent gauze, prepared by impregnating it with gutta-percha. It can be mixed with iodoform or airol. By rolling it up into a ball it can be passed into the uterus, which it distends without absorbing any more blood. As a tampon the gutta-percha gauze retains its elasticity. Hence Schaeffer finds it suitable for inducing abortion.—*British Medical Journal.*

Carcinoma of the Rectum.—Prof. J. Hochenegg concludes a review (prepared for the Moscow Congress) of his 129 operations for cancer and 173 for other troubles of the rectum, with the remark that we seem now to have reached the limit of what we can do for patients in an operative way, with the exception of locating and removing affected lymphatics as in carcinoma of mamma. He found the glands involved in far more than half of his cases. Future progress will be in earlier diagnosis, as surgeons are not to blame for the small percentage of permanent recoveries, the patients being sent to them altogether too late. He rejects the use of the mirror as directly injurious and needless, when the carcinoma is below the sphincter at the edge of the anus, where it can be easily seen; also for carcinoma located in the ampulla, usually in the anterior wall, which is characterized by level, soon ulcerating prominences, spreading later into a ring of infiltration around the whole rectum with a tendency to hemorrhage, slimy diarrheic passages and pain in the lumbar region, the rigid carcinomatous growth holding the lumen open. When located at the sphincter tertius it tends rapidly to a ring formation, with stenosis, violent constipation alternating with diarrhea, and hemorrhage, as fragments of the neoplasm are torn away by some violent evacuation. A specific symptom with this form is the presence of gas in the ampulla, which is very much distended although empty of solid contents. The sensation to the investigating finger is that of a gas-filled balloon. Irrigation, etc., liberates the gases but the condition recurs again in two to three hours, and is a characteristic indication of this form of carcinoma, which is very deceptive to palpation. One day it feels like a solid body projecting into the gas-filled ampulla like the vaginal portion of the uterus into the vagina; another day, after an evacuation usually, it is not to be felt at all. The amount of water that can be injected is an unreliable method of locating the stenosis. A better means is Otis's improved endoscopy, which requires care and experience. There are no typical carcinomatous feces. Mucus merely indicates catarrh, and hemorrhage before, during or after an evacuation may be produced by hemorrhoids. Microscopic investigation also fails to reveal cancerous particles in most cases, and the pains at first are too slight to drive the patient to the physician. Digital investigation and palpation are therefore the chief if not the sole reliance in diagnosing. Where a pelotte is necessary after an operation, he orders for his hospital patients a large sponge, wet and well wrung out, held by an elastic band. In eighty-nine extirpations by the sacral method, since 1887, thirty-two are still living without a relapse, five with relapse, thirty-three died from relapse, seven from an intercurrent disease and four have been lost track of. In two cases there have been normal pregnancies and deliveries. The article is published complete in the *Wien. Klin. Woch.* of August 12.

Constitutionality of Laws Regulating Practice of Medicine.—Under the civil law no barriers were drawn around either professions of law or medicine. Any one who pleased might practice them without any previous qualification, subject always for injuries inflicted upon others. The common law, having an habitual regard for the widest freedom of action and borrowing from the civil law, always favored the right of any man to practice in any profession or business in which he was competent. It was a right inherent in every man to practice the art of medicine. But in modern times the tendency of legislation is to prescribe qualifications for the practice of the professions of law and medicine. Its competency can not be successfully impugned. Learning and good moral character may be required as a condition to the exercise of the rights to practice them. A law enjoining reasonable requirements as to learning and character is simply an exercise of the police power. This power may be exercised in barring from admission those who apply for the right to practice the profession of medicine, and also in excluding those who have been practicing it. Such legislation is justified by the safety of the lives, health and comfort of the people, which is the supreme law. In no case is the practice of medicine a property right. Nor is it a vested right. But it is a valuable right; and no one can, arbitrarily and without reason, be deprived of it. Such is the general statement made by Judge Pugh of the court of common pleas of Franklin county, Ohio, in the case of State v. Ottman, where he holds the law of that State passed February, 1896, entitled "an act to regulate the practice of medicine," constitutional. That it authorizes the medical board to refuse to grant or to revoke a certificate to practice "to any person guilty of felony or gross immorality," he does not consider in violation of the provision of the constitution of the United States which prohibits the passage of any *ex post facto* law or bill of attainder, though it was argued that this was a deprivation of a civil right for past conduct. Neither does he think that it violates the provision which ordains that the citizens of each State shall be entitled to all privileges and immunities of citizens of the several States; nor anything in the fourteenth amendment; nor the constitution of the State, especially in its provisions as to appeals.

Cheap Sanatoria for Consumptives.—Unterberger in the *St. Petersburger med. Wochenschrift* argues that the part played by the bacillus of tubercle in the spreading of the infection of phthisis has been over-estimated. He refers to Riffel's case as a case in point, namely, the instance of a consumptive family occupying for thirty years a small house; several children and five adults died of phthisis in the house. The house was then immediately occupied by another (large) family, and although no kind of disinfection had been undertaken and many years have elapsed, none of the second family have yet developed phthisis. As an instance of what he means by the cure of phthisis, Unterberger narrates the history of Dr. Dettweiler. This physician, aged 58 years, has a family history of phthisis. At 17 years of age (1859) he had chronic pleurisy on the right side; hemoptysis in 1860. In 1867 there were signs of a cavity at the apex of the right lung and much hemoptysis. In 1868 he improved during treatment at Goerbersdorf, but had an attack of pleuropneumonia after giving lectures at Darmstadt. He then became assistant to Brehmer at Goerbersdorf. In May, 1870, he had severe typhlitis, and then, during service in the Franco-German war, had fresh hemoptysis and pulmonary inflammation. After six weeks' rest at Goerbersdorf he was able to return to the war, but on the way back from France had again the signs of a cavity at the right pulmonary apex. He remained at Goerbersdorf, improving slowly, but had an exacerbation in 1875. In this year he went over to Falkenstein, where he has had occasionally hemoptysis or fever, and in 1883 a left pleuritic exudation. In 1884 no tubercule bacilli could be found in the sputum, but after a fresh cold they were again present. Since 1885 no bacilli have been found in the sputum, although there have been occasional slight hemorrhages. He also treats of the experiments that have been made in Europe in organizing simple and cheap sanatoria for phthisic patients. In Russia there are two such sanatoria; Halila in Finland founded by Dittmann in 1883, and Lindheim in Livonia founded by Trew in 1895. The great expense hinders the erection of many large sanatoria, but he maintains that little houses or cottages might be erected at less expense, where consumptive patients might have pure country, dust-free air, good food and hydrotherapeutic treatment and remain under medical supervision as at larger sanatoria. The air may be artificially scented with the aroma of pine trees if the latter are insufficient. With Winternitz he believes that the hydrotherapeutic processes act by increasing phagocytosis. Employers of labor might even be induced to erect small sanatoria of this kind from purely economic considerations.—*British Medical Journal.*

Longevity a Feature of Temperate Climates.—During 1896 the death of 188 persons over 90 years of age, fourteen of them being over 100, was recorded in Great Britain and Ireland. It is a somewhat curious circumstance that the average longevity is greater in Scotland than it is in England, and greater in Ireland than in Scotland, the birth-rate being largest in England and least in Ireland. Of a thousand persons, men, women and children, resident in England, the average number over 60 years of age is seventy-two or somewhat more than 7 per cent. In Scotland the proportion over 60 years of age is 7.7 per cent., and in Ireland it is 10.5 per cent. Ireland stands second to France as regards the longevity of its inhabitants, the proportion of men and women in France over sixty years old being by the last census 12.7 per cent., or 127 of each 1,000 of population. The official figures of the census report show that longevity is, to a considerable extent, regulated by climate, that is, in countries within the temperate zone, the duration of life is greater than in warmer or semitropical countries. The average number of persons over 60 years old in 1,000 inhabitants in the United Kingdom is seventy-seven, and in the German Empire, the climate of which is similar, it is the same. In Holland it is also seventy-seven; in Denmark, eighty-four; in Sweden, eighty-eight, and in Norway, ninety. In Russia the longevity of the inhabitants is greatest in the northern provinces and lowest in the southern ones. The average of European countries in the north temperate zones, England, Germany and Holland, seventy-seven a thousand falls to seventy-one in Austria and in Portugal. In Spain, where the climate is generally milder than in Portugal, the number over 60 years of age, in a thousand, is fifty-eight only, and in Greece it is fifty-six. In the East Indies, as far as there are any authentic figures, the average is only forty in a thousand inhabitants. In South America the average is about fifty, though there are, of course, many exceptional cases.

The Surgical Attributes of the Southern Negro.—Dr. Rudolph Matas, of the Charity Hospital of New Orleans, has made a very thorough statistic study of the records of that hospital as to the surgical peculiarities of the negro of Louisiana. His research, which covers a period of ten years ending 1894, has warranted the conclusion that the race of the patients play little or no part in the prognosis of surgical operations, except in so far as it is influenced by degenerative tendencies due to the hygienic, social and moral environment. He holds the opinion that the colored man of his section is at nearly all points, whether anthropologically, physiologically and pathologically, different from his original African ancestors and from his uncivilized brothers on the west coast of Africa of the present generation. A residence of nearly three hundred years in the southern States of North America, in contact with the white man and under the influence of civilization, has produced a marked change in the mental and physical organization of the negro. This change is evidently due to the combined influences of acclimatization and adaptation to surroundings, and especially miscegenation with the white race. The *International Journal of Surgery* weighs the argument of Dr. Matas and with him concedes that the general morbidity and mortality of the colored race was less than that of the white population in the South, during the whole period of slavery and up to emancipation; but concludes that since the colored race has been thrown upon its own resources, its morbidity and mortality have enormously increased, and are now much greater than those of the white population. While the more typical African diseases are rapidly disappearing, the general liability of the negro to the common diseases of this country is rapidly increasing, so that many immunities which he formerly enjoyed have been lost, and new predispositions to disease have been acquired. There are no conditions, continues the author, which prevail exclusively in the colored race, any more than there are diseases which prevail exclusively in the white race. The differences, pathologically speaking, that do exist between the white and colored population, lie only in their relative predispositions to some of the diseases that prevail in *this country, and in their relative immunity from* others. When viewed from the purely surgical operative standpoint, the white and colored races are practically alike, especially when individuals of both races, taken from the same social environment, are compared. There are no apparent differences between the races on the operating table; the same technique applies to both equally as well, and often, especially in the matter of resistance to shock, the negro appears to better advantage than the white man. *In the general and local reactions of* the tissues to infection, there are some differences in the races. It is in the histogenetic tendencies of the tissues that we find the real surgical contrast between them. If we are to judge from this alone, the colored race reveals in this last particular a marked tendency to degeneration.

English Governmental Report on Glycerinated Vaccine.—The researches of Sir R. Thorne Thorne, M.D., and Dr. Copeman, upon the newer preparations of bovine vaccine, have been reported to the Local Government Board. These reporters visited Paris, Berlin, Brussels and several other cities of central Europe in order to investigate the laboratories where the glycerination of vaccine lymph has been conducted on an extensive scale. Since 1891, Germany especially has been engaged in perfecting a system of vaccination in which the English method of arm-to-arm operations plays no part, and these reporters state that in that nation the laboratories have found it possible to obtain from a single calf sufficient vaccine to vaccinate 6,000 to 15,000 individuals. Whereas, says the *Lancet*, the English governmental vaccine establishment has been content to obtain 200 or 300 vaccinations from each animal operated upon for lymph production. These reporters brought back with them from Berlin a quantity of the glycerinated and most highly diluted lymph and made test vaccinations after intervals of nine to thirty-seven days after collection, and obtained a success of 92 per cent. in their series of seventy-six individuals. With other samples less highly diluted with glycerin there were obtained successes in 100 to 97 per cent., when the lymph had not been subject to a longer interval after collection than thirty-one days. Not only is the activity of the lymph not impaired by the addition of very considerable proportions of glycerin, but this latter agent exerts a distinct bactericidal effect on organisms that accidentally find their way into the vaccine, inclusive of the pus producing germs, which are more or less resistant to many bactericidal agents other than glycerin. Lymph containing an aqueous solution of glycerin has also been experimentally proved to have the property of destroying the vitality of the bacillus of tuberculosis. It is not in terms stated that the glycerinated lymphs were found to be sterile, but that they did not contain those pathogenic forms that may possibly produce erysipelas, suppuration and tuberculosis, the three conditions that have been said to be possibly communicable by the use of the non-glycerinated bovine virus. Economy and a greater safety both point the same way, namely, to the use of glycerin in the preparation and storage of vaccine. The proportion of glycerin added in the different laboratories varies greatly. In Paris the lymph is diluted with equal parts of the agent; in Brussels about two parts thereof are added; in Berlin fourteen parts of a solution of equal parts of glycerin and boiled water are added to one part of the epithelial pulp scraped from the vesicles. These differences can only be settled to the satisfaction of the profession and of interested officials by continued laboratory work, and the reporters point out the necessity for the prompt establishment, in England, of a home laboratory to aid in the settlement of this and allied problems. The question of the centrifugalization of the lymph has been experimented upon in Berlin, but the desirability of this additional measure of purification has not been demonstrated. It is true that the vaccine has a better appearance and shows a smaller amount of micro-organisms, even before the addition of the solution of glycerin, but it is argued that if the activity of the lymph depends upon a particular body "and is locked up specially in the epithelial cells, continued centrifugalization would remove it and the lymph would lose its activity." This is another phase of the question that can only be cleared up by laboratory work. In some of the laboratories the tuberculin test is applied to the calf. In others of the places the reliance as against possible tuberculosis in the animal is placed in the postmortem. The selected animal is closely followed from the time of purchase until that of slaughter. This latter is done in the presence of experts and none of the collected lymph is allowed to leave the establishment until after a thorough examination has been made upon the producing animal and it has been pronounced to be free from tuberculosis.

Bites of Insects and Serpents.—Dr. Gonin of Lyons, sends a note to the Paris Academy of Medicine recommending formol for mosquito and gnat bites, also for bites from small animals. The bites should be covered with formol by a small brush or the surface of the cork of the bottle containing it. After evaporation the formol is again applied. The soothing effect is instantaneous: there is never any inflammation. M. Gonin asserts that formol is efficacious for serpent and scorpion bites.

Hospitals.

The Virginia Hospital and the Richmond (Va.) Male Orphan Asylum each received $10,000 from the late Major Lewis Ginter. St. Luke's Home for the Sick, the Sheltering Arms Hospital and the Richmond Eye and Ear and Throat Infirmary each receive $5,000, while $2,500 goes to Maternity Hospital and $1,000 to Foundling Hospital.——The corner stone of the new Jamaica (L. I.) Emergency Hospital was laid, with appropriate ceremonies, October [illegible].

Societies.

The following meetings are noted:

Connecticut.—New Haven Medical Association, October [illegible]

District of Columbia.—The Alexandria Medical Society, October 5.

Illinois.—Clinton County Medical Association, Clinton, October 5. Medico-Legal Society, Chicago, October 14.

Iowa.—Dubois County Medical Association, October [illegible] Iowa State Medical Association, Des Moines, October 13 and 14. Polk County Medical Association, Des Moines, October 12.

Kentucky.—The Kentucky Medical Association, Richmond, October 5. Southern Medical Association, Bowling Green, November 3 and 4.

Michigan.—Saginaw Medical Society, Saginaw, October 6.

Minnesota.—Minnesota Academy of Medicine, Minneapolis, October 6.

Missouri.—Southwest Missouri Medical Society, Springfield, October 14 and 15.

New York.—Broome County Medical Society, Binghamton, October 5. New York State Medical Association, New York City, October 13, 14 and 15.

Ohio.—Association of Surgeons of the Pennsylvania Railroad Company, Zanesville, October 12. Clark County Medical Society, Springfield, October 7. Columbus Academy of Medicine, October 4. Pickaway County Medical Society, Circleville, October 6.

Pennsylvania.—Luzerne County Medical Society, Wilkesbarre, October 6.

Tennessee.—American Association of Colored Physicians, Nashville, October 15. East Tennessee Medical Society, Knoxville, October 5. Tri-State Medical Society, Nashville, October 12, 13 and 14.

Utah.—State Medical Society, Salt Lake City, October 5.

Wisconsin.—Northwestern Wisconsin Medical Association, Marshfield, October 12.

Ontario, Canada.—Chatham Medical and Surgical Society, October 7.

Washington.

Health of the District.—The report of Health Officer Woodward for the week ended October 9, shows the total number of deaths to have been 97, of which number 51 were white and 46 colored. There were 16 deaths from diseases of the nervous system; 7 of the circulatory; 7 from diseases of the kidney; and 19 from diseases of the respiratory system. There were 5 cases of fatal diphtheria and 3 of typhoid fever.

Central Dispensary and Emergency Hospital.—At the meeting of the Attending Staff recently held, the resignation of Dr. George Byrd Harrison was received and accepted. The Staff tendered him a vote of thanks for his faithful and efficient services and expressed regret at his severing his connection with the institution. Dr. Harrison was director of the clinic of General Medicine, Skin and Venereal Diseases. Dr. Hawkes, who has been traveling in Europe for the past several months, has returned and assumed charge of his department in the Hospital.

Public Health Committee.—A meeting of the Public Health Committee of the Washington Board of Trade was called to order on October 13, by the president, Dr. Samuel C. Busey, for the purpose of preparing the annual report for the year 1897. The principal recommendations, unanimously agreed to, and earnestly recommended, were the reclamation of the Anacostia Flats (Washington's Black Hole of Calcutta), the sewage disposal and water purification work.

Medical Society.—At the regular meeting of the Society, held October 13, Dr. Claytor read a scientific and instructive paper entitled "A contribution to [illegible] of the pulse and its significance." The subject was made further interesting by the exhibition of charts explanatory of the subject. Dr. D. S. Lamb presented some very interesting specimens and gave the histories of hemorrhage into the spinal cord, and human bones excavated from mounds in Florida, [illegible] pre-Columbian syphilis.

Washington Obstetrical and Gynecological Society.—The annual meeting of the Washington Obstetrical and Gynecological Society was held on October [illegible] at the residence of Dr. Magruder, a retired member of the Society. The [illegible] of officers for the ensuing year [illegible]: President, Dr. Thomas C. Smith; vice-presidents, [illegible] and John T. Winter; recording secretary, [illegible] corresponding secretary, [illegible] The following committees were formed: [illegible] Tompkins and Bovee; [illegible] Drs. [illegible] treasurer: publication [illegible] Drs. [illegible]

County Medical Society, held Oct. 7, 1897, the following officers were elected: President, L. E. Maire, M.D.; vice-president, A. H. Steinbrecher, M.D.; secretary, J. H. Sanderson, M.D.; treasurer, C. H. Leonard, M.D.; board of directors, Drs. R. Hislop, R. H. Honner, Dayton Parker, J. A. Patton, C. D. Aaron. The secretary reported the society in a flourishing condition, with a membership of 211.

The Detroit Medical and Library Association at its regular meeting, Oct. 11, 1897, listened to an interesting paper by Dr. Charles D. Aaron entitled "Intestinal Auto-intoxication," in which the Doctor made the statement that the meaning of auto-intoxication was not yet definitely agreed upon, but that it consisted of the retention of normal and abnormal material in the intestines, the result of which is decomposition, putrefaction and fermentation, and that the products of the carbohydrate fermentation gives formic, butyric, lactic and acetic acids, with gases, etc. In albuminous decomposition we get NH_3, leucin, tyrolin, cystin, phenol, indol, skatol, tyrosin, acetan, etc. The Doctor alluded to the fact that a great number of microbes within the intestinal canal generate poisonous ptomains and toxins, which are quickly absorbed, and that when we get this production with the retention in the intestinal tract certain symptoms which show a condition of the digestive, respiratory, circulatory, uropoietic and nervous systems takes place. While there is no proof that this is due to auto-intoxication, yet it is certain that when these poisons are removed the different symptoms disappear. In vertigo we have a symptom which shows itself in the poisoning due to alcohol, nicotin, etc., also headache, neuralgia and vomiting due to cerebral retention. The author stated that constipation was not always necessary in auto-intoxication and said that the more fluid-like the contents of the intestines were the more rapid were the absorption of the toxins, as the urine in diarrheic condition has been found to be quite poisonous, and that patients in a condition of auto-intoxication feel better when constipated than when they have frequent evacuations. The Doctor stated that in cholera patients the absorption of toxins is kept up even when there is frequent evacuations. He cited the digestive disturbances of children, which he claimed could be more easily explained on the lines of auto-intoxication than on the reflex theory, and said that such disturbances of the circulation as tachycardia and other symptoms of vasomotor disturbances are very often due to intestinal auto-intoxication. In certain skin affections as urticaria, this matter is not now recognized as being due to idiosyncrasy, but rather to the intestinal auto-intoxication. He also argued that asthmatic dyspepsia, symptoms of collapse produced by obstruction of the bowel and sclerosis, depended somewhat upon auto-intoxication.

CHANGE OF ADDRESS.

Alford, R. Lee, from Laddonia to Vandalia, Mo.
Allen, W. H., from Horr to Joliet, Mont.

THE PUBLIC SERVICE.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the two weeks ending October 16, 1897.

Medical Inspector J. C. Wise, P. A. Surgeon F. A. Hesler, Asst. Surgeon B. K. Smith, detached from the "Philadelphia" and ordered to the "Baltimore."

Medical Director N. L. Bates, detached from the Museum of Hygiene and ordered to duty as chief of the Bureau of Medicine and Surgery.

Medical Director J. R. Tryon, detached from the Bureau of Medicine and Surgery and ordered to New York as general inspector of United States naval hospitals.

Medical Inspector H. J. Babin, ordered as president of the naval examining board, New York, October 9.

Medical Director C. H. White, detached as president of naval examining board, New York, October 9, and ordered to Washington in charge of Naval Museum of Hygiene.

Asst. Surgeon J. C. Pryor, detached from the naval hospital, Mare Island, and ordered to the "Adams."

Asst. Surgeon A. Farenholt, detached from the "Vermont" and ordered to New York navy yard.

Surgeon C. G. Herndon, ordered on temporary duty at the Naval Museum of Hygiene.

Asst. Surgeon W. B. Grove, detached from naval laboratory, New York, and ordered to Mare Island hospital.

P. A. Surgeon C. P. Bagg, detached from the "Marion" and ordered to the "Adams."

Asst. Surgeon M. K. Johnson, detached from the "New York" and ordered to duty with the "Vicksburg."

Asst. Surgeon R. Spear, detached from the naval laboratory, New York, and ordered to the "New York."

Surgeon C. Biddle, detached from marine rendezvous, San Francisco, ordered to Washington in charge of patient, then report at the Navy Department.

The Journal of the

American Medical Association

Vol. XXIX. CHICAGO, ILL., OCTOBER 30, 1897. No. 18

ORIGINAL ARTICLES.

THE PRESENT STATUS OF PREVENTIVE MEANS AGAINST THE SPREAD OF TUBERCULOSIS IN THE VARIOUS STATES OF THE UNION CRITICALLY REVIEWED.

Presented to the Section on State Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, June 1-4, 1897.

BY S. A. KNOPF, M.D. (Paris and Bellevue, N. Y.)

PHYSICIAN TO THE LUNG DEPARTMENT OF THE NEW YORK THROAT AND NOSE HOSPITAL; FORMER ASSISTANT TO PROFESSOR DETTWEILER, FALKENSTEIN SANATORIUM, GERMANY; FELLOW OF THE NEW YORK ACADEMY OF MEDICINE, ETC., NEW YORK.

In order to ascertain the exact condition of prophylaxis in regard to tuberculosis, I have addressed letters of inquiry to all the secretaries of the State boards of health of all the States and Territories of the Union, and to the health officers of forty of the largest cities. To all the gentlemen who by their prompt replies so kindly aided me in compiling this report, I wish to express my sincere thanks and appreciation. Here are the results of my inquiries:

Alabama.—No laws or regulations concerning tuberculosis in man or beast, and no circulars issued.

Arkansas.—No laws, regulations or circulars concerning tuberculosis. Dr. Jennings, the executive officer, writes that the State not having made any appropriation, the board is handicapped for want of funds.

California.—Good bovine laws and regulations, circular issued on consumption.

Colorado.—Good bovine laws and regulations and a special circular, "How to prevent the spread of consumption in Colorado."

Connecticut.—Good bovine laws enforced by the State Board of Agriculture, and a circular on consumption, its cause and means of prevention.

Delaware.—Circular on the prevention of consumption.

District of Columbia.—Only one law in regard to tuberculosis, which forbids the sale of milk that may be tuberculous. No circulars or public notices.

Georgia.—There was formerly a State board of health but it has been allowed to become extinct for lack of appropriation.

Idaho.—No State board of health. Provision is made for the appointment of health officers by the various boards of county commissioners, but they are answerable to the local authority only.

Illinois.—The board has never passed any laws or resolutions concerning tuberculosis and no circulars have been issued.

Indiana.—No bovine laws yet, but the question is agitated. The board issues 2,000 quarterly bulletins free to all county, city and town health officers, and to others who may subscribe for them.

Iowa.—The board is very active in educating physicians and laity in regard to tuberculosis and is enforcing its bovine laws with vigor.

Kansas.—No laws, regulations nor circulars concerning tuberculosis in man or beast. The legislature failed to make any appropriation and the State veterinary office is abolished.

Kentucky.—For want of appropriation, the board has undertaken no work in regard to bovine tuberculosis, but a circular on consumption has been issued.

Louisiana.—Circulars are sent to physicians, and stations for the free examination of sputum have been established, but *the attempts of the board to* secure legislation in regard to bovine tuberculosis have been thwarted by concert of action on the part of the ignorant and prejudiced Creoles, who have almost entire control of the dairy business.

Maine.—The cattle commissioners are authorized to slaughter tuberculous cattle and reimburse the owners, and the board has issued a circular on consumption.

Maryland.—No laws, regulations or circulars on tuberculosis.

Massachusetts.—Five cattle commissioners appointed by the Governor are entrusted with the suppression of bovine tuberculosis. A circular on the best means of preventing consumption is issued.

Michigan.—The State Live Stock Commission is entrusted with the work concerning the suppression of bovine tuberculosis. Circulars for public instruction are issued. Sept. 30, 1893, resolutions were adopted *to include consumption in the official list of* diseases dangerous to the public health.

Minnesota.—Good bovine laws. I received no report in regard to provisions concerning tuberculosis in man.

Mississippi.—No laws, regulations or circulars concerning tuberculosis in man or beast. With the reorganization of the board, better work is hoped for.

Missouri.—No answer to my inquiries, but I learn from the daily paper that the State Board recommends public lectures on the question in the more populous centers, and all pupils of the public schools throughout the State be given a course of instruction in the causes of consumption and means by which it may be prevented.

Montana.—No State board of health.

Nebraska.—The board at present is a mere licensing body without sanitary powers.

New Hampshire.—No special regulations on the prevention or restriction of tuberculosis, but some papers on the subject have been printed. In 1891 the legislature enacted a law creating a State Board of Cattle Commissioners.

New Jersey.—The State Board of Agriculture enforces the bovine laws and a circular on consumption has been issued.

New Mex[illegible] e Te[illegible] oard has noti[illegible]d the increase of phthisis among natives of the Territory and has traced many cases to an exposure to possible infection, New Mexico being a favorite resort for consumptives. Circulars on consumption are profusely distributed and last year the board passed resolutions encouraging the testing of domestic animals with tuberculin.

New York.—Good bovine laws not very rigidly enforced because the State appropriation is small. Most efficient work was done at first by the Tuberculosis Committee of the board, but there was no appropriation last year, in spite of the fact that it has been demonstrated that there are at this time 75,000 tuberculous cows in the State.[1] Circulars like those of the New York City Board have been issued. To New York belongs the credit of having done the pioneer work in educating the public to the dangers of tuberculosis. The State board requests all local health officers to register name and address of every person suffering from tuberculosis within their respective jurisdictions.

North Carolina.—No laws, regulations or circulars concerning tuberculosis in man or beast.

North Dakota.—No laws, regulations or circulars concerning tuberculosis in man or beast.

Ohio.—No bovine laws. A circular on the prevention of consumption has been issued.

Oklahoma.—There is a law prohibiting the sale and use of milk from cows not in proper condition of health. Nothing else is done in regard to the prevention of tuberculosis.

Oregon.—No State board.

Pennsylvania.—The State Live Stock Sanitary Board is entrusted with full power to suppress bovine tuberculosis. The Board of Health has passed resolutions that tuberculosis be added to the list of communicable diseases dangerous to the public health. Circulars are issued and the Pennsylvania Society for the Prevention of Tuberculosis is in a flourishing condition, although it does not receive any aid or encouragement from the State.

Rhode Island.—Circulars are freely issued. Sputum is examined free of charge and $10,000 yearly is expended to enforce bovine regulations.

South Carolina.—No bovine laws. Some years ago circulars were printed and distributed, but no more appropriation for this purpose having been forthcoming nothing is now done.

South Dakota.—There is a law providing for the destruction of tuberculous animals and carcasses; nothing concerning tuberculosis in man. Provision is hoped for from the next legislature.

Tennessee.—Circulars on the prevention of tuberculosis in man and beast have been issued. There are bovine laws, but owing to want of funds the board has been deterred from formal action up to this time.

Texas.—The Quarantine Department is the highest sanitary authority. Its powers are limited to epidemic diseases. Circulars on tuberculosis have been sent to physicians. There are no bovine laws.

Utah.—No board of health or any organization of a similar kind whatsoever.

Vermont.—No answer, but I learn indirectly that this State kills tuberculous cattle and recompenses the owner.

Virginia.—Bovine laws are enforced by the Board of Control of the Experimental Station of the Virginia Agricultural and Mechanical College at Blacksburg. Circulars on the restriction of consumption are issued.

West Virginia.—No bovine laws. Circulars on consumption have been issued.

Wisconsin.—The board of health and the State Veterinarian co-operate in destroying milch cows that are tuberculous. Circulars on tuberculosis in man are issued.

Wyoming.—No State board of health. During the legislative sessions of 1895 a bill was introduced to create one, but it was not passed. Sanitary regulations are left to the cities, some of which have boards appointed by ordinance.

This gives us: Fourteen States which have bovine laws and regulations and in which circulars are issued for public instruction in regard to tuberculosis in man, viz.: California, Colorado, Connecticut, Iowa, Maine, Massachusetts, Michigan, New Jersey, New Hampshire, New York, Pennsylvania, Rhode Island, Virginia and Wisconsin; two which have bovine laws but where apparently nothing is done to stop the spread of tuberculosis in man, viz.: Minnesota and South Dakota; one which has bovine laws but can not enforce them for lack of funds and where thus far the board has only issued circulars on the prevention of tuberculosis in man and beast, viz.: Tennessee; two (the District of Columbia and Oklahoma Territory) which have a law prohibiting the sale of tuberculous milk, but nothing else concerning tuberculosis in man or beast; eight which issues circulars of instruction concerning tuberculosis in man, but where nothing is done in regard to bovine tuberculosis, viz.: Delaware, Indiana, Kentucky, Louisiana, New Mexico Territory, Ohio, Texas and West Virginia; nine where nothing is done to stop the spread of tuberculosis in either man or beast, viz.: Alabama, Arkansas, Illinois, Kansas, Maryland, Mississippi, North Carolina, North Dakota and South Carolina; seven which have no board of health, viz.: Georgia, Idaho, Montana, Nebraska, Oregon, Utah and Wyoming; five from which I have received no answer, viz., Florida, Missouri, Nevada, Vermont and Washington.

To the letters addressed to the health officers of forty of our largest cities I received twenty-nine answers. In one-third of these it was stated that nothing at all had been done concerning the prophylaxis of tuberculosis.

This state of affairs speaks for itself and shows that as a nation we have a most limited protection from tuberculosis in man and beast.

Let us consider for a moment the injustice done to States with good laws in regard to bovine tuberculosis by those which have no such laws. Where interstate traffic exists it will be well-nigh impossible for the States with good sanitary laws to suppress bovine tuberculosis within their borders. The following incident which I have from a reliable source will show a danger and injustice to which a State with good laws is no doubt frequently exposed: A farmer in a State with no laws to suppress bovine tuberculosis entered into a compact with a friend residing in a neighboring State where the government kills all tuberculous cattle and recompenses the owner; all the worthless cattle which he can procure are driven across the line to the friend. At the next visit of the State veterinary surgeon these cattle are found tuberculous, ordered killed and, considering their real value, handsomely paid for. The farmer and his friend divide the profit. This may be the first direct loss in money to the State with good laws, but how many times may not these diseased cows, secretly imported, be the cause of infecting whole herds of valuable cattle? And yet the citizens of the State with good laws in regard to tuberculous cattle, though imposed upon, are to be envied, for the State with no such laws is an unsafe place to live in. The following extract from the "Eighth Biennial Report of the Iowa State Board of Health" will show how true this is. "Some time since the State veterinary surgeon found a lot of cattle which he condemned as tuberculous, placing them under quarantine and expecting in a day or two to slaughter them. Upon his return he found that the cattle had been sold to be shipped out of the State for food." The seller claimed that he had fully made known the condition of the cattle to the buyer and thus the law could not reach him. The danger from tuberculous meat, milk and butter has been, I fear, underestimated in years past, and I am willing to admit that I, myself, in previous publications, have considered with many others the dissemination of the germs contained in carelessly deposited sputum of tuberculosis patients the prime and most important factor in communicating the disease to others, but I recently undertook to trace the etiology in regard to antecedents, environments, personal and family history, in as many published cases as I could procure accounts of, and I was surprised to find in how large a number one was justified in excluding the inhalation of bacilli, as the etiologic factor. A farmer, cowboy, gardener, wood-chopper or any other individual living most of the time in the open air, residing in an isolated district where consumption is rare or almost unknown, with no family history of tuberculosis, sickens and dies of pulmonary phthisis. Now, while it is true that primary intestinal tuberculosis is of relatively rare occurrence in adults, we can account for this by the fact that they do not take tuberculous milk as their exclusive nourishment as may be the case with an unfortunate child whose delicate intestinal epithelium becomes the abiding place of the tubercle bacillus contained in countless quantities in every meal the child takes. In the adult the ingested bacillus, in the majority of cases, seems to pass through the lymphatic system into the circulation of the blood to find its favorite lodging place in the badly ventilated apices. It is well known that the bactericidal quality of the gastric secretions is insufficient to destroy the germ of tuberculosis[2] and the only defence against this mode of invasion seems to be the good phagocytic power of the blood of the healthy individual. Now when we consider that milk, butter and meat of cattle constitute the most important and universally used articles of food for man and how relatively recently laws in regard to bovine tuberculosis have been enacted at all, and in how many States such laws do not yet exist, I think it is not surprising when looking into the exact etiology of cases of pulmonary consumption that we find a very large number must certainly have been caused by the ingestion and not the inhalation of the bacillus.

[1] Cassidy and Smith: "Tuberculosis—It is the Duty of the State to Suppress the Greatest Destroyer of the Human Race."

After arriving at this conclusion, I was much gratified on a recent visit to Dr. von Ruck's sanatorium in Asheville, N. C., to hear his opinion in this matter. He told me that to judge from a carefully kept history of many thousand cases from all over the United States which have come under his observation, the majority of cases of pulmonary tuberculosis, in his opinion, had their origin in the ingestion of tuberculous food of some kind. Dr. F. W. Smith of the Tuberculosis Committee of the State Board of Health of New York seems to be of a similar opinion, for he wrote me, "the first great step toward the prophylaxis of tuberculosis in man is to stamp out the disease in cattle."

Let us then, in our war against tuberculosis, divide our attention equally between the bacilli which may be ingested and the bacilli which may be inhaled, and we may then perhaps hope for a victory.

To effectually combat tuberculosis in cattle and other domestic animals, the Federal Government, having equal jurisdiction over all the States and Territories, is alone capable to do the work. How this should be accomplished enters not into the scope of this paper. Abler men than myself will outline the workings of such a National institution which might justly have its center in the Bureau of Animal Industry in Washington, which has already done such excellent work in the direction of preventing bovine tuberculosis.[3] But as physicians entrusted with the care and preservation of the lives of American citizens, we should appeal to the United States Government to take the matter of stopping the spread of tuberculosis through the bovine race into its own powerful hands. By a judicious legislation and proper enforcement of laws in this direction thousands of precious human lives would be saved, and individuals and communities would ultimately be spared the loss and destruction of valuable livestock and property.

While the advisability of Federal laws in regard to the prevention of human tuberculosis may be contested, there is one feature of the prophylaxis of consumption which seems to me should enter into the domain of Government supervision. I refer to the disinfection of passenger and sleeping cars. This seems to me especially desirable and needful on roads much frequented by pulmonary invalids. The insanitary arrangement of these vehicles, especially the sleeping cars, must be evident to any one who has given the matter any attention. Only a few weeks ago when going south I had three traveling companions in the more advanced stages of pulmonary tuberculosis, one unable to leave his berth during the daytime. They were all male patients, and with them the rest of the male passengers, the conductor, the trainman and the colored porter enjoyed the privilege of one drinking glass. The patients coughed and expectorated a good deal, sometimes hitting and sometimes missing the small hole in the flat cuspidor, which contained no liquid whatsoever. Draw your conclusions from this as to the safety of the innocent traveler with a little bronchitis entering this car in a condition of accidently enfeebled health, or with a natural predisposition to consumption. A few days later I returned with the same car and I am sure it had not been disinfected since I traveled in it southward.

Now I am told that it is impossible to hinder a consumptive from entering a Pullman car, and that if there were a law whereby he could be prevented from doing so, it would be well nigh impossible to enforce it. I grant this to be true, but if our wealthy railroad corporations which habitually carry consumptives to and from health resorts could be induced to run ambulance cars, especially adapted to the purpose, a good deal of danger now existing would be done away with. If these ambulance cars would offer to the traveling consumptive only twice the ordinary breathing space, and if the railroad company would be magnanimous enough to have a trained nurse in charge of each car, the accommodations thus offered would be eagerly sought by all invalids; even an additional price would not deter the average patient from making use of this mode of travel, which would certainly lessen to a marked degree the many discomforts from which he has to suffer in the ordinary sleeping car. Wire mattresses, leather cushions, linen curtains, special cuspidors, and linoleum instead of carpets, with better ventilation generally, could make of such a "Pullman" a model ambulance car, easily disinfected, and a credit to the respective company. But a regular, thorough cleaning and disinfection of all passenger cars at stated intervals should be made obligatory.

[3] Salmon, D. E., D.V.M., Chief of the Bureau of Animal Industry. "The Federal Meat Inspection."

Smith, Theobald, M.D., *Chief of the Division of Animal Pathology*, Bureau of Animal Industry: "Some Practical Suggestions for the Suppression and Prevention of Bovine Tuberculosis."

We now come to the subject of tuberculosis as transmitted from man to man in the ordinary walks of life. As to the mode of transmission there is no longer a doubt; all the circulars issued agree on the fact that the main danger lies in the dried and pulverized tuberculous expectorations; but as to the mode of preventing a tuberculous patient from communicating his disease the recommendations vary. Some are simply impossible to carry out, some are useless, and some not without danger.

It is in a spirit of kindness and in the interest of all that I venture the few following criticisms:

All the circulars issued have already done a great deal of good, but the more practicable and feasible the prophylactic measures recommended therein, the more their usefulness will be increased. Prophylaxis in theory is one thing, but put into practice in everyday life it is another.

In the circular issued by the State Board of Health of California we read as follows: "Persons inheriting the liability to consumption should, above all things, avoid the presence and habitations of persons afflicted with consumption." Now who are the persons inheriting the liability to consumption? They are the sons and daughters of tuberculous parents; and they should, above all things, avoid the presence and habitations of persons afflicted with consumption! If the parents are dead, these children may be able to avoid those afflicted with pulmonary phthisis, but if the parents are living, and especially if in poor circumstances, it will be very difficult, often well nigh impossible, for them to avoid the presence and habitations of the unfortunate ones afflicted with the disease. I am convinced that a practical instruction how to live and remain well, even when obliged to live with consumptives, and even if from tuberculous parentage, would be of more real value. In Europe and in the United States the positions as internes in sanatoriums for consumptives are eagerly sought by many of our unfortunate colleagues who have a hereditary taint, or who have often already developed the disease, and I am glad to say that they often get well in these institutions.

The State Board of Delaware recommends that in case the house has no drain, the contents of the spit-cups be buried in ground that will not soon be turned up. Now Lortet and Despeignes[4] have shown by experiments that the earthworm is instrumental in bringing to the surface the bacilli from buried tuberculous substances, and that the bacillus does not lose its virulence from its sojourn in the earth or in the interior of the earthworm. This mode of disposing of the tuberculous material is then hardly recommendable, and it is certainly not safe for animals to pasture in the vicinity of spots used for the purpose of burying tuberculous expectorations. A previous destruction of the bacilli by boiling or addition of a 5 per cent. carbolic acid solution would certainly be the safer way.

The otherwise excellent circular issued by the State Board of Health of Maine contains exactly the same provision in regard to the sputum of tuberculous patients.

The New Jersey State Board recommends that tuberculous patients should not empty their pocket cups, which are to be carried to receive their expectorations when on the street or when traveling, until boiling water has been poured over the contents, and that the water should be allowed to cool in the cup. What is the poor fellow to do when his little cup is filled and he is still away from home or not in a place where he can procure boiling water to pour over the contents of his cup and wait for it to cool? Even if the water is really boiling the contents of the cup will cool it somewhat, and even a temperature of 100 degrees C. will not kill the bacilli at once. From the experiments of Schill and Fischer[5] one must conclude that it takes at least five minutes of steady boiling to destroy the virulence of the tubercle bacilli contained in fresh sputum. The addition of some some bicarbonate of soda will raise the boiling point to a degree (102 or 103 degrees C.) where the bacilli will be quickly and surely killed.

But all we can reasonably expect of a tuberculous patient is that when he expects to be long away from home, he shall provide himself with a small bottle of carbolic acid, 5 per cent. solution, a small quantity of which he will put in his pocket flask every morning before leaving the house. When it becomes necessary to empty the flask he will do so in the water-closet, or if he is on the street and this is not possible, in the gutter at the mouth of the drain. He will then put another small quantity of carbolic acid in the cup.

In this same New Jersey circular I miss the very important caution about the danger of kissing on the mouth, and that spoons, forks, glasses, napkins, etc., through the medium of the saliva of tuberculous patients may become the vehicles of transmitting the disease.

The Ohio State Board circular on "How to Avoid Consumption" says: "In selecting a mate in marriage choose one free from any inherited scrofulous or tuberculous taint." How many will this deter from marrying whomever they please? And if we could, have we a right to debar an individual with an inherited taint from ever marrying? Have not thousands been cured from such a taint? I would rather say that people who have inherited such a taint can, by a judicious mode of living and with proper medical care, overcome such a condition: but they should never marry until their medical adviser finds them completely recovered from that peculiar state known as predisposition. I would further plainly state that for people suffering from tuberculosis, or not completely cured, to marry with the idea of raising a family, means in the majority of cases, the rapid shortening of the wife's life and the probable bringing forth of diseased children. A tuberculous mother rarely lives more than a few months after the birth of her child.

[4] *Lortet and Despeignes: Académie des sciences, Paris, January 2 and July 4, 1892.*

[5] Straus, "La Tuberculose et son Bacille." Paris, 1895.

At its regular meeting, May 10, 1894, the State Board of Health of Pennsylvania passed the following resolution: "That this board strongly recommends to all local Boards of Health that they require returns of tuberculosis when it has reached the infectious stage, from all physicians and householders, in the same manner that the returns of other infectious diseases are now required." Is tuberculosis not an infectious (*i. e.*, communicable) disease the moment the presence of the bacillus can be demonstrated in the saliva or expectoration? Tuberculosis must be considered a communicable or infectious disease at all times and stages, and the greatest danger from tuberculous patients is at the time when they are still up and around, following their usual vocations but disseminating at the same time through careless expectoration, myriads of bacilli every day, until they become too weak to walk about and are obliged to confine their insanitary habits to one room. If prophylactic measures are to be effectual, they must be instituted at the earliest possible moment in the course of the disease.

In nearly all the movements inaugurated by the State Boards of Health to prevent the spread of consumption, there is a conspicuous lack of regulations concerning hospitals, public or private, which receive tuberculous patients. How necessary such regulations are, I felt when visiting recently an institution in a State where much is done in the direction of prophylaxis. This institution receives nearly 200 patients annually, the majority being consumptives. The following is one of the rules conspicuously posted throughout the house: "Patients must at all times, when in the institution or on the verandas, expectorate in the sputa cups provided. They must never expectorate in the sinks, wash-basins, closets, or on the floor or in their handkerchiefs." Outside the institution the patients are not restricted, they may expectorate wherever they please and I have no doubt they do. I was told that a neighboring farmer who had some time ago bought five healthy cows had them tested recently with the result that three were found tuberculous. I wonder if at times man is not responsible for transmitting his disease to animals.

I may say here, that in nearly all the institutions I visited I noticed the most frequent sanitary defects whenever the institution was without a house physician. It seems to me it should be obligatory for such establishments to provide a resident physician. A minister, matron or a sister superior is hardly the proper person to see that the hygienic and prophylactic demands of modern phthisio-therapy are carried out to the letter.

Well conducted special hospitals for the consumptive poor are the urgent need of all our great cities. Their usefulness would be many times increased if each State would provide a suitable sanatorium for the convalescent and early cases.

The Board of Health of the City of New York has endeavored to inforce registration of all tuberculous cases. The great majority of the profession has opposed any attempt in that direction as untimely. Still, the careless and ignorant consumptives should be controlled and prevented from doing harm by some restrictive measures. The same Board and many other city boards have passed ordinances forbidding expectorating in street cars or on the floors of public buildings, and some even make it punishable to expectorate in the street. But any one who observes at all will be surprised to note how little these ordinances are heeded.

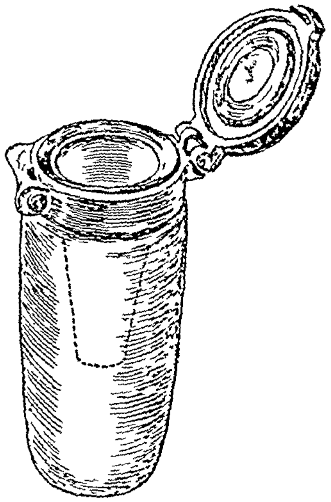

Fig. 1.—Dr. Knopf's modified pocket flask for tuberculous patients.

But do we ever think how really hard it is for a naturally sensitive consumptive to be a law-abiding citizen in this respect? Not to expectorate on the floor or in a handkerchief, but to attract the attention of everybody to his infirmity by his peculiar mode of disposing of his expectorations? Try it once yourself. I occasionally carry a pocket flask and expectorate intentionally therein when riding in the street cars. I wish you could see the eyes sometimes turned on me. And still, I think a more universal use of the pocket flask, not only if we are tuberculous, but also when we have a simple cold, would solve the problem of promiscuous spitting in public and in private.

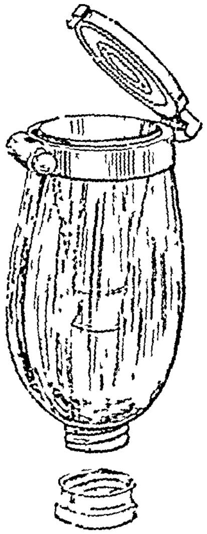

Fig. 2.—Dr. Dettweiler's "Hustenflaeschchen."

The use of the handkerchief for the purpose of expectorating, while better than spitting on the floor, is certainly not very sanitary [illegible] hav [illegible] loubt, at times, is the cause of a sev [illegible] ti [illegible] e nasal mucous membrane. And [illegible] n [illegible] thing unesthetic in the discreet use of a neat pocket flask, such for example as the one you see here.

It is a modification of Dettweiler's celebrated "Hustenflaeschchen," which I also show you.

My flask differs from Dettweiler's inasmuch as it is made of aluminum instead of glass, weighs two ounces instead of six, is of two pieces instead of three and is not patented. It is unbreakable and easily cleaned. Like Dettweiler's, it is constructed on the principle of the irreversible inkstand. It has a nearly uniform diameter of one and three-fourths inches and is about four inches long. It is less bulky than the oval glass flask. Since we must consider the proper spittoon, properly placed, as an important factor in the prophylaxis of tuberculosis, allow me to present you with two drawings, one showing Predoehl's practical cuspidor of enameled iron for factory and workshop use, which can be attached to any height, and the other my own elevated spittoon for hospitals or sanitariums, only visible when in use.

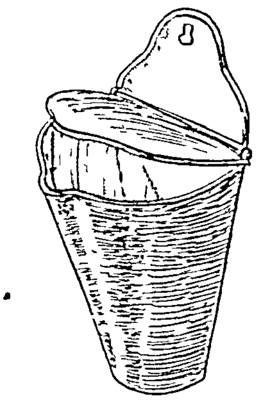

Fig. 3.—Dr. Predoehl's spittoon for factories and workshops.

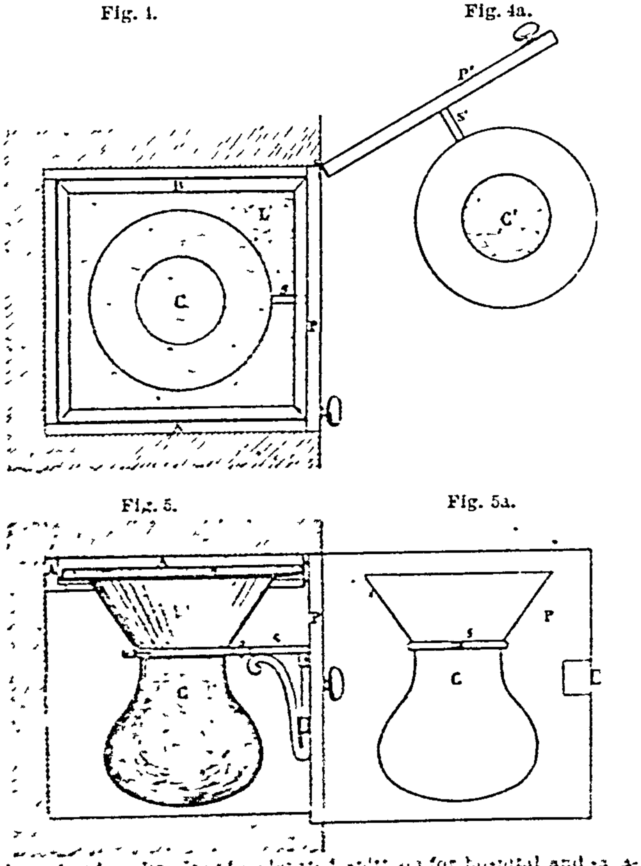
Fig. 4. Fig. 4a. Fig. 5. Fig. 5a.



Figs. 4 and 5.—Dr. Knopf's elevated spittoon for hospital and sanatorium use. Spittoon elevated some feet from the floor and inclosed in the wall. P, door or hinged support. C, spittoon. B, cover. [illegible] 4 and 4a, plan, 5 and 5a, elevation. Figs. 4 and 5 represent the door closed, 4a and 5a represent door open.

Our dispensaries should be supplied with pocket flasks to be distributed gratuitously, or at cost price, to all coughing patients, with instructions for using them.
